normal mean value. The average for the whole of Macedonia and Thrace was 7.25%. The figures for men, women, and children were 7.31, 7.34, and 7.10 g. % respectively. At first it was thought that the rather high protein values might be associated with malaria, but an examination of the data showed that there was no consistent relation between these two. The lowest protein figure was found in the Florina region for children at 6.98 g. % and the maximum figure in the Nigrita region for women at 7.56 g. %. There was no striking difference between the various regions or between the villages in the same region.

Haemoglobin Estimations

The mean average haemoglobin level for men, women, and children of Macedonia and Thrace was 12.75 g. %. The average figure for men was 13.65 g. %, for women 12.31 g. %, and for children 12.16 g. %. Of the population of Macedonia and Thrace 29% had haemoglobin levels of 12 g. % or below; 10% of the men, 38.3% of the women, and 34.8% of the children were below this level. Thus the number of women and children below this level is nearly four times greater than that of the men. In Table VIII the percentage at or below the 12 g. % level is given for all the different regions.

TABLE VIII.—Percentage of Haemoglobin at or below 12 g. %

	Men	Women	Children	Total	Regional Spleen Index %
Florina ..	0.0	11.9	16.5	11.6	13
Kilkis ..	3.2	22.3	17.9	14.8	28
Nigrita ..	19.4	50.0	33.0	33.8	46
Salonika ..	9.8	34.4	41.8	34.2	31
Komotini ..	14.9	50.6	58.5	42.6	36
Xanthi ..	13.0	51.0	41.0	37.3	43
All regions ..	10.0	35.3	34.8	29.0	33

The lowest figures were consistently found in Thrace in the Xanthi and Komotini regions, where the levels for women were 11.7 and 11.9 g. % respectively. The maximum figures were found in the Florina region, with an average for men, women, and children of 13.5 g. %. It was in the Florina region that the proteins were lowest, but not below normal. This lack of correlation between blood proteins and haemoglobins has been noted by other workers. We have no explanation for

the low haemoglobin levels in the Xanthi and Komotini region. Perhaps the fact that they are predominantly tobacco-growing areas may have a bearing. Alternatively, it may be connected with the rather high proportion of Turks in these regions. We have found that in villages with both Turks and Greeks it is always the Turkish section that has the lower haemoglobin level, and the Turks are generally the more wretched. Whether this is due to economic discrimination, indolence, or race has not been investigated—the fact is merely reported.

These haemoglobin figures for Macedonia and Thrace do not compare unfavourably with those of Britain and the U.S. In Britain, Davidson *et al.* (1943) found that among the municipal school children of Edinburgh 39% had haemoglobin levels of 11.04 g. % or below; that among female

factory workers 23% had haemoglobin levels between 8.7 and 11.0 g. %, and that 72% of pregnant women had values of 11.0 g. % or below. In the U.S.A., Milam and Anderson (1944) found that white and negro children in North Carolina had average values of 13.0 and 12.3 g. % respectively, that white and negro males had 14.6 and 14.1 g. % and white and negro females had values of 13.1 and 12.5 g. %. In Florida, Abbott and his co-workers (1945) found the mean values for male and female

Chart showing mean haemoglobin and protein levels.

adults to be 11.45 and 11.74 g. %, with 43% of their subjects having values ranging from 3.6 to 11.4 g. %.

This relatively favourable haemoglobin picture from Macedonia and Thrace when compared with Britain and the U.S.A. needs qualification. The relation of haemoglobin levels to malaria in Greece is by no means a simple one, and cannot be assessed only on the basis of spleen indices. As is well known, the endemicity of malaria in Greece varies from year to year; in some years it is high, in others low, and periodically it takes on an "epidemic" form, accompanied by the occurrence of large numbers of cases of blackwater fever. After several seasons of low endemicity the distribution of spleen size will differ from that found after an epidemic; after the former there will be a greater proportion of the larger "spleens," while after the latter there will be a relatively higher proportion of small spleens. In addition, after years of low endemicity the relation of the parasite index to the spleen index will be far from unity, while after an epidemic the spleen and blood indices will more nearly approach one another. Similarly the widespread use of antimalarial drugs will be expected to reduce the parasite index more quickly than the spleen index.

Spleen Indices

If spleen indices only are taken into account there appears to be no consistent relation between them and haemoglobin levels, as is shown by a comparison between two villages in the Nigrita region—Flamouri and Nikolona. In the former the spleen index was 87% and the haemoglobin level 12.35 g. %, whilst in Nikolona, with a spleen index of only 36%, the haemoglobin level was 12.33 g. %. The relation of the parasite index to haemoglobin levels appears to be more direct. Fairley (1934) has shown that in chronic cases of malaria the anaemia is far from severe, while in acute cases the blood

picture is quite otherwise. A similar situation has been found to exist in the field in Greece. In Flamouri, where the spleen index was 87%, the parasite index was 9% and the haemoglobin level 12.35 g.%; in Mikis the spleen index was 69%, the parasite index 37%, and the haemoglobin level 11.5 g.%. It is to be expected, then, that in years of high endemicity or during epidemics when the blood-parasite index is high the haemoglobin level will be lower than in years when malaria is less rife and the parasite index is lower. The last four years in Greece have been ones of low malarial endemicity in most parts of the country, and the haemoglobin levels were higher than they would have been if this survey had been carried out after an epidemic or a number of years of high endemicity. It is important, then, to realize that the haemoglobin picture in Greece will vary from year to year, according to the malaria situation, and that the present survey probably shows the haemoglobin at its peak. In such circumstances it is extremely difficult to assess the relative importance of malaria, poor diet, and economic status on haemoglobin levels.

As pointed out in a previous paper (Foy and Kondi, 1939), the rural populations of Macedonia eat meat not more often than two or three times a year; other proteins are of course eaten, such as peas, beans, cheese, and less frequently eggs and sour-milk products. So far as we are aware there is no deficiency of iron in the diet here, but a thorough-going nutritional survey has yet to be made in Macedonia by a competent team of workers. In the past the low intake of meat has been regarded as not unconnected with the great prevalence of hyperchromic macrocytic anaemias in Macedonia (Fairley, Bromfield, Foy, and Kondi, 1938), where they form some 55% of all the anaemias occurring in the country. A consideration of all these facts would make it appear that malaria is not the only nor the most important factor concerned in the anaemia picture of Macedonia and that diet may occupy an important place. The dietary deficiency may not be the same as that in Britain or the U.S.A., as is evident from the greater prevalence of macrocytic hyperchromic anaemia here.

Summary and Conclusions

A protein, haemoglobin, and malaria survey has been made over a wide area of Macedonia and Thrace to investigate the relation of these indices to one another and to diet. In all, some 1,500 blood protein estimations and 2,500 haemoglobin estimations have been made, and 3,500 spleens have been examined.

The proteins were all within normal range, in some regions above the normal mean value. The figures for men, women, and children were 7.31, 7.34, and 7.10 g. % respectively. The mean average for the whole population was 7.25 g. %. No consistent relation was found to exist between protein values and spleen indices.

The mean average haemoglobin level for men, women, and children was 13.65, 12.31, and 12.16 g. % respectively. The mean value for the whole population was 12.75 g. %. Of the whole population 29% had levels that were at or below 12 g. %; 10% of the men were at or below this level, 38.3% of the women, and 34.8% of the children. Thus there were nearly four times as many women and children at or below the 12 g. % level as there were men.

There were no consistent relations between low haemoglobins and high spleen indices; there was, however, a closer relation between parasite indices and haemoglobin values. Spleen and blood parasite indices in Greece vary from year to year, according to the severity of malaria. In years of low endemicity the spleen and blood parasite indices will not approach one another very closely—that is, the spleen rates may be high and the blood-parasite rates low: in years of high endemicity or after epidemics the blood-parasite and spleen rates will approximate much more closely. It follows, therefore, that the haemoglobin level will vary from year to year and will be much more directly related to the high blood-parasite indices than to high spleen indices, as in fact has been found to be the case in acute and chronic malaria.

The relatively favourable haemoglobin levels found in the present survey is accounted for by the fact that the past four years in Greece have been years of low endemicity in most parts of the country. The present figures, obtained during a transmission- and relapse-free period, may be taken as probably representing the peak haemoglobin level of Macedonia and Thrace.

The large proportion (55%) of hyperchromic macrocytic anaemia present in Macedonia and Thrace at all times makes it seem likely that there are other factors as well as malaria that are concerned in the anaemia situation in this part of Greece. So far as is known there is no deficiency of iron in the diet. In the past the very low intake of animal protein, which is eaten only two or three times a

year, has been regarded as related to the high incidence of these macrocytic anaemias.

No relation was found to exist between blood-protein levels and haemoglobin levels; nor were there any constant differences between the haemoglobin and protein values for the mountain and plain areas.

AN INVESTIGATION INTO CERTAIN TONGUE CHANGES IN BRITISH TROOPS

BY

B. H. SMITH, M.B., Ch.B.
Formerly Lieut.-Col., R.A.M.C.

(From the Nutrition Section, Department of Hygiene and Pathology, Medical Directorate, General Headquarters, India)

The object of the present investigation was to determine the incidence, clinical picture, and, if possible, the cause of a symptomless tongue condition which was occurring among British troops in India and South-East Asia Commands, and which was giving rise to diagnostic difficulties. The principal features of this condition were fissuring, epithelial changes, and changes in the architecture of the papillae. The most probable aetiology was considered to be a nutritional deficiency, probably of riboflavin.

Briefly, the incidence and macroscopic appearance of these tongues were investigated among troops who had been two years in India or on the Burma Front, and for comparison a similar investigation was carried out on British troops fresh to India from the U.K. Therapeutic trials were carried out to demonstrate the effects of thiamine, riboflavin, and niacin on such tongues. All tongues were examined in a good light, both naked eye and with the aid of a $\times 6$ lens. The same macroscopic tongue appearances were found both in troops fresh to India and in those who had served there for a considerable time. Only the incidence of the condition differed in the two groups.

Principal Features

Fissuring.—Difficulty was encountered in defining what constituted fissuring. For the purposes of this investigation all tongues which showed furrows other than the normal single antero-posterior furrow were accounted fissured. Fissures of all grades of severity were seen and were classified according to the depth and width of their troughs. Where they were shallow, appearing as a parting between the papillae, the term mild was applied. Where they were deeper and their troughs were sunk below the level of the papillary bases, the term moderate was applied. Fissures which were deep and wide were listed as severe. Besides differing in depth and width the fissures varied in number, position, and length. Some were sagittal, some coronal, some oblique, some straight, some curved; they varied from a few millimetres to a few centimetres in length; in number they varied from two or three to twelve to fifteen.

The fissuring sometimes occurred alone, sometimes in association with other tongue changes, such as epithelial stripping, loss of fur, or alterations in the papillary architecture, described later. In no case did the patients complain of sore tongue; evidence of inflammation was absent.

Of special interest was a condition in which the whole dorsum and edges of the tongue were the site of multiple deep wide fissures. A number of men with such tongues stated that the condition had been present from birth, or from as far back as they remembered. In these tongues markedly hypertrophic papillae of fungiform shape were a feature of note. These were undoubtedly cases of "scrotal tongue" and were of little clinical significance.

Epithelial Changes.—The following three main types of epithelial changes were encountered.

Type I.—The patches were single or multiple, round or irregular, and varied in size from a match-head to a sixpence. Over these patches fur was either entirely absent or thinner than that of the surrounding dorsum, giving in consequence a redder appearance to the patch. These areas were transient, appearing and disappearing at different sites on the dorsum for no apparent reason. They sometimes occurred alone, sometimes in association with other tongue changes.

Type II: Geographical or "Mapped" Tongue.—In this connexion multiple areas devoid of fur, similar to the patches seen in Type I, were found, most commonly along the edges but also on the dorsum of the tongue. They were distinguishable from the preceding, however, by a distinctly demarcated border, usually incomplete and consisting of a thickened whitish-grey epithelium. This thickened border gradually advanced over the tongue, leaving behind it an area devoid of normal papillae and fur; *pari passu*, the receding edge of the furless area assumed a normal appearance, so that periodic examinations revealed a change in the "map" of the tongue. The significance of this irregular desquamation of the tongue is unknown. Geographical tongue was always associated with fissuring of greater or less degree.

Type III.—Here red, shiny patches, often circular and the size of a shilling or less, occurred centrally on the posterior third of the dorsum. They were sometimes irregular and sometimes enclosed islands of normal epithelium. Over these areas the papillae were absent. In some cases the area was subdivided by multiple tiny cracks, like a crazy-pavement; in some it was quite smooth. The appearance was suggestive of a past inflammation in which the specialized papillary epithelium had been lost and the area covered with a flattened epithelium. If this is the explanation the contraction of the subepithelial connective tissue would explain the fissures. Sometimes the patch was covered with a delicate white epithelium, like a fine film of paper, giving an appearance similar to a mild localized leucoplakia.

Papillary Changes.—Variations in the general papillary architecture were also noted. In some tongues the dorsum was covered with a uniform papillary mat which made it difficult to differentiate, naked eye, the filiform and fungiform papillae. In others the fungiform papillae, especially at the edges, were prominent and injected. This appearance was only transient. In all the scrotal and severely fissured tongues many large mushroom-shaped papillae were found.

Fissuring, epithelial changes, or the papillary changes apart from injection did not seem to be related to the soldiers' age, length of service, use of dentures, alcohol or condiment consumption, or to tobacco smoking.

TABLE I.—Showing Incidence of Fissuring and Epithelial Changes

	U.K. Group		Burma Front Group	
	No.	%	No.	%
Total examined ..	2,390		761	
Tongue changes ..	240	10.04	112	14.7
Fissuring ..	225	9.4	97	12.73
Severe ..	12	0.5	5	0.65
Moderate ..	42	1.75	22	2.89
Mild ..	171	7.15	70	9.19
Epithelial changes ..	73	3.05	46	6.04
.. plus fissuring ..	53	2.22	31	4.07
.. alone ..	15	0.62	15	1.97
Fissuring alone ..	167	6.98	66	8.6

In Table I the comparative incidence of fissuring and epithelial changes in the tongues of troops recently arrived in India and of those who had been fighting on the Burma Front are given. It will be noted that the incidence of both fissuring and epithelial changes is greater in the Burma Front Group

than in the U.K. Group, the increase in epithelial changes being relatively greater than the increase in fissuring. The differences in incidence are significant statistically as seen by χ^2 test. It will be seen from the table that epithelial changes occurred more often in fissured than in non-fissured tongues. The significance of this is unknown, but it suggests that fissuring and epithelial changes are part of a common syndrome or that the fissured tongue is more liable to epithelial changes.

Other Evidence of Nutrition Deficiency

During the tongue examination signs of nutritional deficiency were looked for in the general condition of the soldier, in the eyes, mouth, skin, etc. The only sign of possible nutritional origin discovered was angular stomatitis. In the U.K. Group four cases were seen among 2,390 men examined; in three it was associated with fissuring of the tongue, in the fourth there was no other sign of possible nutritional import.

Among 761 men who had served on the Burma Front, three cases of angular stomatitis were seen; in two mild fissuring was present, in the third there was no lingual abnormality. In none of the cases of angular stomatitis in either group was the condition severe. The usual appearance was a sodden thickened epithelium at the angles of the mouth without actual cracking.

Therapeutic Tests and Results

To demonstrate the effects, if any, of certain vitamins of the B complex on these tongue conditions, 80 men, showing one or more of the tongue changes described, were selected for therapeutic trials. Men showing similar tongue changes were paired off, and to one man was given vitamin supplements while his "twin" received no supplements and was simply observed as a control. Thirty-one men received five compound vitamin tablets per head daily for 24 days (each tablet containing thiamine 1 mg., riboflavin 1 mg., niacin 10 mg., and ascorbic acid 25 mg.); 10 men received five lactoflavin tablets (each containing 1 mg. of riboflavin) per head daily for 15 days. One man receiving vitamins and one from the control group fell out during the course of the experiment.

During the investigation all the men subsisted on the same scale of rations, all underwent the same training, and the two groups lived so far as possible under comparable conditions. The health of the men studied remained good throughout the investigation. In particular there were no cases of diarrhoea.

To minimize subjective influences, drawings were made of the tongue condition at each examination, and a decision whether there was improvement, deterioration, or no change was attempted. The results are shown in Table II. It will

TABLE II.—Effects of Supplements of Compound Vitamin Tablets and of Lactoflavin on Fissuring and Epithelial Changes

	Experiment using Compound Vitamin Tablets		Experiment using Lactoflavin Tablets	
	Experimental Group	Control Group	Experimental Group	Control Group
Fissuring:				
No improvement ..	24	24	6	7
Improvement ..	4	5	3	1
Epithelial changes:				
Type I { No improvement ..	3	4	0	No control
Improvement ..	4	2	1	No control
Type II { No improvement ..	0	1	0	No control
Improvement ..	0	0	0	No control
Type III { No improvement ..	5	3	1	0
Improvement ..	0	0	0	0

be seen from the table that neither in the cases of fissuring nor in the cases of epithelial changes were there any significant improvements due to vitamin administration. A note was also kept of the papillary architecture of the tongues under observation. No significant alteration was observed as a result of vitamin therapy.

Discussion

The frequency among British troops in India and South-East Asia Commands of tongue changes suggestive of nutritional deficiency made the verification or refutation of this diagnosis a matter of importance. From the first it appeared improbable that certain of the cases investigated were due to inadequate

iet; many cases of severely fissured tongue gave a lifelong history of the condition, and two cases of geographical tongue actually appeared after the addition of vitamin supplements to the diet. As, however, there was little to distinguish the tongue changes in cases giving a helpful history from those with no such history, it was considered best during the investigation to lump all the cases together.

In favour of the diagnosis of deficiency diseases was the dietary history. In the forward areas where these tongues were first noted the dietary of the troops was giving rise to anxiety. Their ration scale on paper contained adequate amounts of all the essential nutrients, but in practice their ration was not being implemented, and it was doubtful whether even minimum requirements for calories, thiamine, riboflavin, niacin, and ascorbic acid were being met. Cases of undoubted primary malnutrition among British troops, apart from loss of weight, were nevertheless rare. The chief evidence adduced in support of doubtful cases was the tongue changes here described. The fact that such tongues were present in significantly greater numbers among men who had been in S.E.A.C. for a considerable period than among troops fresh from the U.K. lent weight to a nutritional aetiology. Refined laboratory tests in support of this diagnosis were not possible.

There were factors against deficiency disease as the cause. While many of the tongues were suggestive of B hypovitaminosis, and several might have passed as cases of hyporiboflavinosis, it is significant that no cases were found which conformed with the textbook picture of advanced deficiency. This was all the more striking because typical textbook tongues of riboflavin deficiency were occurring among large numbers of Indian troops in the same region; among them generalized redness and pain were features of note which were not found in British soldiers. Further, the tongue lesions of hyporiboflavinosis among sepoys were generally accompanied by other evidence of the deficiency such as angular stomatitis, skin changes, etc. Among the British cases under consideration such corroborative evidence was exceptional. It has also been shown by Thomson and Freedman (personal communication) that the tongue lesions of riboflavin deficiency in Indian troops clear up after 5 mg. of riboflavin daily for 14 days. Kruse (1942), on the other hand, in his investigations into the tongue manifestations of niacin deficiency, stressed the long period required for recovery, and talked in terms of 200 mg. of nicotinamide daily for 14 months to effect a cure. It is realized that in the therapeutic trials carried out on British troops the vitamin dosage was small, the courses short, supplements of only well-known vitamins were given and it is not certain whether they were absorbed from the gut, but the absence of a favourable response to thiamine, riboflavin, and niacin exhibition was against a deficiency of these vitamins being causative. Again, the occurrence of similar tongue changes (albeit less frequently) among troops fresh to India and among those living in the base areas of India, all of whom had been subsisting on a diet adequate on modern standards, makes nutritional deficiency appear unlikely as the cause.

To sum up, it is considered that the balance of evidence is against the tongue changes investigated being of nutritional origin. An alternative explanation cannot be offered at present. The chief object in publishing this paper is to draw attention to the frequency of tongue changes which are apt to be diagnosed as due to deficiency disease and to enjoin caution in their acceptance as such.

Summary

A tongue condition occurring frequently among British troops and characterized by fissuring and changes in the epithelium and architecture of the papillae has been investigated.

The frequency was less among troops fresh from the U.K. than among those in base areas of India or on the Burma Front.

No improvement in the condition followed treatment with thiamine, riboflavin, and niacin.

I am grateful to Mr. C. K. Dilwali for statistical assistance. My thanks are due to the D.M.S. in India for permission to publish this paper.

BATTLE EXHAUSTION

REVIEW OF 500 CASES FROM WESTERN EUROPE

BY

EILEEN M. BROOKE, M.Sc.

E.M.S. Statistical Branch, Norcross

In both the 1914-18 war and that of 1939-45 it has been found that the stress of battle conditions sooner or later proves too much for some men and a breakdown occurs. The effects of this may be short-lived, return to the fighting zone being possible after a few days; but in more serious cases a long period of treatment may be required, and even then it may be necessary to discharge the patient from the Forces. During the fighting on the Western Front it was possible to treat the least serious cases on the spot, but in the more severe cases it was found necessary to remove the casualties altogether from the theatre of war and send them home, in many instances to special neurosis centres. An analysis of the medical records of 500 such cases admitted to E.M.S. hospitals since D-Day has been made by the Ministry of Health Statistical Branch at Norcross, where a survey of the records of every fifth admission for in-patient treatment is being carried out. All of the 500 cases were admitted with a diagnosis of battle exhaustion (Medical Research Council Morbidity Code VX/9496/6X), and were not simultaneously suffering from either trauma or disease. Although such a diagnosis depends to some extent on the medical officer, this fact should not invalidate the statistical comparisons which follow.

The figures for the population at risk were not available, and therefore 5,000 wounded men admitted to E.M.S. hospitals from the Western Front during the period from D-Day to the end of 1944 have been used as a basis for comparison. For the sake of contrast, figures of admission for non-combat neurosis have also been extracted for 1942 and 1943, the years for which the statistics are complete. These have been compared with the corresponding total admissions for all diseases, excluding the infective and acute respiratory infections, which are unduly liable to seasonal variation.

TABLE I.—Percentage Distribution of Battle Exhaustion and Non-combat Neurosis Cases by Age (Males)

	Age Groups				
	15-24	25-34	35-44	45-54	55+
Battle exhaustion (M.R.C. Code VX/9496/6X)	48.6	44.6	6.4	0.4	—
Wounds and other injuries from the Western Front (Codes 80-96)	46.5	47.0	6.3	0.2	—
Non-combat neurosis:					
Anxiety states (Codes 3320 and 3321)	24.2	50.0	23.7	2.0	0.1
Hysteria (Code 3324)	30.9	46.5	21.0	1.5	0.1
Psychoneurosis (unspecified) with somatic symptoms (Codes 3330-9)	33.6	42.7	21.4	2.3	—
All diseases (excluding infective and acute respiratory)	33.6	44.8	19.3	2.1	0.2

Comparison of the age distribution of battle exhaustion cases with that for all injuries on the Western Front shows so little difference that it does not appear that any particular group is more prone to combat neurosis than to any other form of accident. The same applies to non-combat neurosis patients admitted for unspecified forms of psychoneurosis with somatic symptoms, and in a lesser degree to cases of hysteria, when these groups are compared with the general average for all non-infective and non-respiratory illness. The proportional incidence of anxiety states is markedly below the average for ages 15-24, and well above for the 25-34 group.

The distribution of days of in-patient treatment shows little variation for the age groups 15-24 and 25-34, and the median periods are approximately equal. For the age group 15-24 the distribution shows that 11.4% were treated for less than 2 weeks, 14% from 2 to 4 weeks, 31.2% from 4 to 8 weeks, 32.9% from 8 weeks to 3 months, and 10.5% over 3 months; while, for ages 25-34, 11.8% were treated less than 2 weeks, 12.8% from 2 to 4 weeks, 27.7% from 4 to 8 weeks, 36.8% from 8 weeks to 3 months, and 10.9% over 3 months. The numbers in the higher age groups are too small for any

TABLE II.—Length of In-patient Treatment for Battle Exhaustion and Non-combat Neurosis

Days of In-patient Treatment:	0-	4-	10-	14-	21-	28-	42-	56-	91-	182	Not Stated	Total	Med (day)
Age Groups	No. of Cases											Total	Med (day)
15-	4	11	11	18	14	22	49	75	23	1	15		
25-	1	14	11	11	17	23	38	81	22	2	3		
35-	1	1	—	4	3	1	8	9	3	—	2		
45-	—	—	—	—	—	—	1	—	1	—	—		
55+	—	—	—	—	—	—	—	—	—	—	—		
Total	6 (1.2%)	26 (5.2%)	22 (4.4%)	33 (6.6%)	34 (6.8%)	46 (9.2%)	96 (19.2%)	165 (33.0%)	49 (9.8%)	3 (0.6%)	20 (4.0%)	500 (100%)	51
Distribution of 400 cases of non-combat neurosis	0.5%	8.8%	4.2%	10.5%	5.8%	16.2%	15.5%	27.7%	9.8%	1.0%	—	100%	41

conclusion to be based upon them, but from the distribution it does not appear that age is a factor affecting the length of treatment needed. For 400 cases of non-combat neurosis selected at random the median period of treatment was 45 days.

TABLE III.—Length of Service in the 1939-45 War

	Years of War Service							Total
	0-	1-	2-	3-	4-	5 and Over	Not Stated	
Frequency	22	73	55	46	127	98	79	500
Percentage of known cases	5.2	17.3	13.1	10.9	30.2	23.3	—	100%

That only 5.2% of the patients whose period of service was known had had less than 1 year's service may simply reflect the fact that the complexity of modern warfare necessitates longer training before exposure to battle conditions. Men with 4 to 6 years' service accounted for 53.5% of the breakdowns. Of 127 with 4 years' service, 36 had had previous battle experience—8 in France and 28 in the Mediterranean theatre; while of 98 with 5 years' service 16 had been in the fighting in France and Norway and 28 in the Mediterranean. The incidence of breakdown is greatest in those with less than 2 or more than 4 years' service. This may be compared with the experience of Minski (1945), who found that in a series of 54 wounded patients with neurosis, 46 had extremes of service—either 1 to 1½ years, or 4 years or more. It might have been expected that exposure to battle stress would develop a form of resistance to those external causes which promote fear. But for a number of men who had successfully endured all the hardships of the North African campaign, followed in many cases by the Sicily landings, it seemed as if the cumulative effect of their experiences had exhausted all their reserves, leaving them nothing with which to face a new trial. In all, 99 men with varying lengths of service had previously been exposed to battle stress, and of 60 for whom information was given 27 had previously broken down, including 11 who had been treated in neurosis centres.

The view has been expressed that it is not the immediate strain which causes breakdown, but rather a constitutional predisposition. Slater (1943) in an analysis of the records of 2,000 neurotic soldiers found that 55.7% of these men had one or

more first-degree relatives—parent, sib, or child—with definite neurotic illness, psychosis, epilepsy, or some form of psychopathy such as drink, shiftlessness, or violent habits. Ballard and Miller (1945), discussing psychiatric casualties in the R.A., found a positive family history in 60% of all cases of both sexes. In the battle exhaustion series information as to family mental history was given in 169 cases, of whom 71.6% had at least one first-degree relative with neurotic traits, psychopathy, psychosis, epilepsy, mental deficiency, or insanity. A series of 400 records of non-combat neurosis a positive family history was found in 69% of the 248 cases for whom information was given, 60% having at least one unstable first-degree relative. The distribution of such relatives is shown in Table I and rather lends colour to the view that in some families there is an inherent underlying defect, which may manifest itself outwardly in a variety of forms of unstable conduct. The high percentage—71.6—of battle exhaustion cases with an adverse history of first-degree relatives might be accounted for by the fact that, while such individuals adapt themselves more or less successfully to their normal environment, any extraordinary situation exerts a selective action and brings them to notice.

Apart from adverse hereditary factors, a history of previous neuroticism was often found. Compared with 66 records of normal childhood there were 237 in which one or more neurotic traits were mentioned, including 17 who were dull and backward; the frequency with which the symptoms occurred was "nervy" or neurotic, 119; fears, 50; somatic symptoms, 46; shy and solitary, 39; moody, 16; sleep disturbance, 14; breakdown, 10. It was not possible from hospital records to obtain comparative frequencies of family or personal abnormalities in any group of "normal" men, since questions on these matters are rarely put to patients admitted for wounds and injuries.

It has been found that the rate of breakdown is low among the civilian population (Ballard and Miller, 1945), and this is attributed to a better ability to bear strain among familiar surroundings. The rate is also low among submarine crews, despite the dangers of their work.

With a view to seeing whether one type of unit or another was more productive of breakdown cases, the 500 battle exhaustion cases were analysed by units and compared with a similar analysis of 5,000 injury cases from Western Europe

TABLE IV.—Distribution of Unstable Relatives among Men with Battle Exhaustion and with Non-combat Neurosis

Type of Disability	Battle Exhaustion										Non-combat Neurosis									
	Father only	Mother only	Father and Mother	Father and Sibs	Mother and Sibs	Father, Mother, and Sibs	Sibs	Other Relatives	Family Unspecified	Total	Father only	Mother only	Father and Mother	Father and Sibs	Mother and Sibs	Father, Mother, and Sibs	Sibs	Other Relatives	Family Unspecified	Total
Mental disease*	2 (1)	2 (2)	2 (2)	—	—	6 (2)	5 (4)	2 (2)	—	19	3 (2)	—	1	1 (1)	5 (3)	1	3	5 (4)	—	19
Epilepsy	—	1	—	—	—	—	3	—	—	4	1	—	—	2	—	1	6	4	—	14
Psychosis . .	—	2	—	—	—	—	—	—	—	2	5	—	2	—	—	2	1	—	—	131
Neurosis	14	40	23	5	11	11	9	4	9	126	20	43	17	20	21	22	21	—	14	13
Psychopathy	1	1	3	—	—	1	—	2	2	10	4	2	—	—	—	—	—	—	—	—
No. of men with adverse family history	17 (14%)	46 (38%)	14 (11.6%)	3 (2.5%)	4 (3.3%)	6 (5%)	16 (13.2%)	4 (3.3%)	11 (9.1%)	121 (100%)	33 (19.4%)	46 (27%)	10 (5.9%)	12 (7.1%)	12 (7.1%)	10 (5.9%)	26 (15.3%)	6 (3.5%)	15 (8.8%)	150 (100%)

* Under this head figures in parentheses denote the number under treatment in mental hospitals.

In only a few cases was the difference between the numbers derived from the two samples very much more than that due to the chance involved in sampling. In the Infantry and R.E.M.E. the incidence of battle exhaustion cases was significantly less than that of all injuries, while in the Paratroops, R.A.M.C., and A.C.C. it was higher. Hence it does not appear that there is any distinction between offensive and passive units in the proportion of breakdowns.

The predominant symptoms accompanying breakdown were somatic, both in the battle exhaustion cases and in those of non-combat neurosis. While both showed a high incidence of symptoms referable to the nervous system and special senses, the latter showed a much higher frequency of symptoms in the gastric and genito-urinary systems. The incidence of sleep disturbance was higher in battle exhaustion cases, probably due to 13.4% of all patients having battle dreams. The percentage frequency of the various symptoms is given in Table V.

TABLE V.—Frequency of Symptoms per 100 Patients with Battle Exhaustion and Non-combat Neurosis

Symptoms	Battle Exhaustion	Non-combat Neurosis
Somatic symptoms :		
Nervous system	94.2	72
Special senses	31.6	40
Cardiovascular and glandular ..	1.2	19
Respiratory	0.4	12
Upper gastro-intestinal tract ..	4.6	27
Abdomen	6.6	11
Genito-urinary	1.2	40
Limbs	4.6	7
General	7.0	8
Sleep disturbance	32.4	24
Fears	14.8	17
Depression	11.6	14.5
Moodiness	8.6	24
Suicidal tendencies, etc. ..	0.4	2.5

Various reasons were given by the patients to account for their breakdown: 167 could not face shelling, 56 complained of blast, 48 broke down when their friends were killed or injured, 16 were exhausted by being in the front line for days on end, 14 could not endure horrible sights, 10 were trapped in burning vehicles or buried alive, 7 gave domestic worry as a reason, 5 broke down when separated from their unit; only 3 admitted to a fear of being killed or wounded, and one complained of inability to keep up with younger men. After treatment it was found necessary to discharge 5.6% of the patients from the Army; 17.6% were returned to duty, and the rest recategorized or treated under the annexure scheme.

The analysis made here does not suggest that age, length of service, previous battle experience, and type of unit are factors affecting the incidence of combat neurosis, but rather that the causative agent is an inherited predisposition to one or another form of instability.

Summary

A statistical analysis is presented of a random sample of 500 cases of battle exhaustion from Western Europe.

Distributions according to age, duration of treatment, and length of service are given.

A comparison is made with 400 patients admitted for non-combat neurosis.

I am indebted to Dr. Bernard Hart, Consultant Adviser to the E.M.S., Sir Francis Fraser, Director-General, E.M.S., and Dr. Percy Stocks, General Register Office, for their help and suggestions.

Routine medical inspections to the number of 13,782 on the children attending the primary and secondary schools of Liverpool have shown excellent nutrition in just over 5% of the children, and that in 93.8% the nutrition could be assessed as normal. The proportion in whom the nutrition was slightly subnormal was 1.15%, and in 0.02% it was considered to be bad. These results are given in a report on the work of the School Health Service submitted to the Liverpool Education Committee by Dr. W. M. Frazer. A study has also been made on the school-children from the point of view of physical measurement, from which it appears that at the present time both boys and girls, for the respective age-groups, were heavier than the boys and girls in 1911. The boys aged 12 are, on the average, 12.4 lb. (5.6 kg.) heavier and the girls 10.2 lb. (4.6 kg.).

ABACTERIAL PYURIA PRESENTING AS "URETHRITIS"

BY

A. B. FIELDSEND, M.B., Ch.B.

Captain, R.A.M.C.; Graded Venereologist

In view of the increasing recognition given to this clinical syndrome (Donovan, 1945; Peters, 1946), the records of these cases, noted over a period of three months at a military hospital in the United Kingdom, are presented in detail. I trust this will lead to a better understanding and treatment of cases previously labelled "urethritis" or "cystitis" of unknown origin.

The patients reported sick, or were referred to a special treatment centre, on account of a persistent urethral discharge. Two cases had been seen on previous occasions and were given courses of sulphathiazole, urethral irrigations, and intravenous fever therapy (T.A.B. vaccine), but with no permanent relief from their symptoms.

Three Case Histories

Case 1.—Pte. X, aged 25, seven years' service, had gonorrhoea in 1940, and mild synovitis of the left knee since April, 1945. He first noticed a urethral discharge, accompanied by an increasing frequency of micturition, with the passing of cloudy urine, in May, 1945. He had been treated at three different special treatment centres in the U.K. in June, August, and October, 1945, for non-specific urethritis, with the usual sulphathiazole courses, but with no permanent relief. Examination on Nov. 8, 1945, revealed scanty urethral discharge, mild circinate balanitis, uniform turbidity of bladder urine after acidification, mild synovitis of left knee, with little or no pain on movement; rectal examination, N.A.D. An early morning urethral smear showed numerous pus cells and a few epithelial cells. Urine: pus cells, +++; albumin, +; aerobic culture sterile. A radiograph of the knee revealed no bony changes. Kahn and gonococcal complement-fixation tests negative. Urethroscopic appearances and prostatic secretions were normal. On Nov. 9, 25 million units of T.A.B. vaccine (Army laboratory preparation) were given intravenously. A good pyrexial response, 103° F. (39.4° C.), was obtained, but with no clinical improvement. On Nov. 13, 15, 17, and 24, 0.3 g. of neosarsphenamine were given intravenously (total 1.2 g.). Frequency ceased and the urine cleared within 48 hours of the first injection. No clinical change was noted in the knee condition. A follow-up one month later revealed no recurrence of urinary complaint; knee i.s.q.

Case 2.—Pte. Y, aged 29, five years' service, had "urethritis" on Oct. 10, 1945. He was treated with sulphathiazole (20 g.), silver nitrate (1:3,000), and irrigations twice daily, and was apparently cured. When first seen on Nov. 6, a diagnosis of non-specific urethritis was made on account of the urethral discharge. He was given 25 million units of intravenous T.A.B. vaccine; pyrexial reaction, 102° F. (38.9° C.), and urine cleared. He was discharged to duty and surveillance. On Nov. 24 he reported sick with recurrence of urethral discharge and marked frequency of micturition. Examination revealed muco-purulent urethral discharge, uniform turbidity of bladder urine after acidification, and mild almost painless synovitis of right knee (a past history of trauma to the knee was admitted); rectal examination, N.A.D. An early morning urethral smear showed numerous pus cells and a few epithelial cells. Urine: pus cells, +++; albumin, +; aerobic culture sterile. A radiograph of the knee revealed no bony injury or disease. Kahn and gonococcal complement-fixation tests negative. Urethroscopic appearances and prostatic secretions were normal. From Nov. 25 to 27 he was given 20 g. of sulphathiazole, with no clinical improvement. On Dec. 3, 5, 7, and 14, 0.3 g. of neosarsphenamine were given intravenously (total 1.2 g.). Frequency ceased, and the urine cleared within 48 hours of the first injection. No clinical change was noted in the knee condition. A follow-up one month later revealed no recurrence of the urinary complaint; knee i.s.q.

Case 3.—Pte. Z, aged 22, two and a half years' service, had no past history of V.D. He was exposed to risk of infection on Oct. 13, 1945. He reported sick with a urethral discharge and frequency to a special treatment centre on Nov. 26. All tests for active V.D. were negative. He was transferred to the surgical ward for treatment of "cystitis." Urine: pus cells, +++; albumin, +; aerobic culture sterile. Cystoscopy revealed a contracted bladder, capacity 3 oz. (90 ml.), with an acute inflammatory condition of the bladder mucosa. He was given 25 g. of sulphathiazole over five days, without any clinical improvement. Examination on Dec. 11 revealed muco-purulent urethral discharge and uniform turbidity of bladder urine after acidification (some shreds in the specimen); rectal examination, N.A.D. An early morning urethral smear showed

numerosus pus cells. A further examination of the urine gave similar results (culture sterile). Kahn test negative. Urethroscopic appearances and prostatic secretions were normal. On Dec. 13, 15, 17, and 28, 0.3 g. of neoarsphenamine were given intravenously (total 1.2 g.). Pronounced clinical improvement was noted within 48 hours of the first injection. The urine became completely clear after the third injection. A follow-up one month later revealed no recurrence of urinary complaint.

Discussion

These cases had all received the recognized treatment for cystitis and urethritis, but in no case had a permanent cure been effected. Specific urethritis was excluded. A cystitis was assumed in all cases, but no organism could be detected after repeated attempts at culture. In the two cases presenting a synovitis of the knee old gonococcal infection was excluded.

Causation is discussed by Donovan (1945). Renal causes were excluded in his series of cases, and a virus cause was suggested; but I question whether organic arsenicals have any therapeutic value in a virus infection (cf. Peters, 1946). According to Lydon (1945) recurrent attacks simulating pyelitis occur during the course of *Trichomonas vaginalis* infection in the male. In view of this I venture to suggest *T. vaginalis* as a possible cause of "abacterial pyuria." Since I had not seen that article before treating the cases, *T. vaginalis* was not excluded as a possible cause of the condition. Stovarsol, an organic arsenical, is widely used in the treatment of this infection in the female. Therefore it is not unreasonable to assume that an intravenous arsenical may reach and destroy such an organism attacking the bladder mucosa in the male.

As the three cases in question had received prolonged treatment by the recognized therapeutic measures, with no permanent relief, the effect of intravenous neoarsphenamine is dramatic in its action. Follow-up was limited to one month because of constant troop movements, etc., but no recurrences of the condition were reported. It would be interesting to know whether any other investigations have been carried out exploring the possibility of *T. vaginalis* as a potential cause of "abacterial pyuria."

Summary

The clinical picture and the histories of three soldiers, originally diagnosed as cases of "non-specific urethritis" but who were found to be suffering from "abacterial pyuria," are recorded in detail.

Causation of this syndrome is discussed. All patients responded dramatically to a course of four injections of 0.3 g. neoarsphenamine given on the first, third, fifth, and twelfth days.

At a meeting of the British-Yugoslav Association, with Mr. Somerville Hastings, M.P., in the chair, Mr. J. N. BARRON, the retiring chief surgeon to the U.N.R.R.A. plastic surgical unit at the Belgrade Hospital, spoke recently on medical problems of rehabilitation in Yugoslavia. He emphasized that the terribly high rate of amputation in that country, affecting all sections of the people, was the result of incredible hardships of mountain resistance over a period of years in the struggle against the common enemy. As the Allies gave both material and moral support to the resistance, by which countless Allied lives were saved, some responsibility rested upon them to help the Yugoslavs to solve their medical problems with regard to the maimed, blinded, and wounded adults and children. With the lack of doctors and of medical supplies they were faced with an exceedingly grave situation. So far as Mr. Barron could estimate, there were well over 15,000 men and women who had lost their legs as a result of war injuries. The plastic surgery unit had been endeavouring to cover the whole field of accident surgery; this was an immense problem and the hospital had commitments of over 10,000 cases, but in six months Mr. Barron's team had been able to look after less than 400 of these. The primary function of the team had been to train Yugoslav personnel: the treatment of patients, notwithstanding its importance, was secondary to the great need of training others who could carry on the work. A major problem in surgery was that of the thousands of war-injured children. Asked about the future of plastic surgery in Yugoslavia when U.N.R.R.A. closed down he said he wished to stir up interest in Britain, the United States and elsewhere, so that the work now being fathered and financed by the Administration could be carried on. In his judgment Yugoslavia needed help in a programme to solve its surgical problems, and this should extend over the next eight or ten years.

Reviews

THE BRONCHIAL TREE AND LUNG ABSCESS

The Anatomy of the Bronchial Tree. With special reference to the Surgery of Lung Abscess. By R. C. Brock, M.S., F.R.C.S. Oxford Medical Publications. (Pp. 96; illustrated. 42s.) London: Oxford University Press, 1946.

In this volume Mr. Brock attempts to achieve two objects: first to give a coherent account of the anatomy of the bronchial tree and its implications, and secondly to furnish a topographical guide to the surgeon who has to drain lung abscess. Until recently the anatomy of the bronchial tree has been neglected by the anatomist, and the account of it given in the book not only gives a clear picture of our present state of knowledge, but adds much original work by the author which has previously only been available in several journals. Particularly noteworthy are his accounts of the distribution of the bronchi of the axillary area of the upper lobe and those of the lingula; in the former, he adopts a terminology which is rather different from that usually used, but he gives good reasons for it. The last chapter includes a description of the commoner abnormalities of the bronchi which is very interesting and useful.

To the physician, his demonstration that in the recumbent position lipiodol normally flows into areas in the upper part of the lung where spreads of tuberculosis frequently occur affords a possible explanation of some difficult problems. The sections on the surgical treatment of lung abscesses are excellent, and in no other book is such a clear and comprehensive guide available. As a work for the specialist physician or surgeon it is difficult to praise it too highly, and it will probably become the standard textbook on the subject. The reproductions of bronchograms, however, are so good that it seems pity that they are not separately indexed so that they could be used for reference by those who have to interpret bronchograms less frequently.

Most readers are heartily tired of the utility type of production of books generally available at present; but the way in which this volume is produced brings the hope that it is the forerunner of a return to pre-war standard. The x-ray pictures come out very well and show the conditions described clearly; some of the lipiodol shadows show evidence of being touched up, but only sufficiently to clarify them. The book is one of the few which can be recommended without any qualifications to all who are interested in its subject.

WORK ON STROPHANTHIN

Strophanthin. Clinical and Experimental Experiences of the Past 25 Years by Bruno Kisch, M.D. (Pp. 158. No price given.) New York City: Brooklyn Medical Press, 2700, Broadway.

The preface states that this monograph has been written for the purpose of urging the American medical profession to reconsider the question of the clinical application of strophanthin. The author was previously professor in Cologne and came under the influence of the late Albert Fraenkel, who introduced strophanthin for the treatment of heart disease in 1906. Fraenkel was impressed by strophanthin as an agent for intravenous injection which had much less cumulative action than the glycosides of digitalis, and of which injections could be given with safety at intervals of 48 hours, knowing that by the strophanthin of the previous injection had been completely excreted. Owing to deaths which followed the use of too high doses, few doctors were converted to the use of strophanthin, though in 1925 Vaquez succeeded to some extent in popularizing its use in France. In this country strophanthin was known to be a substance of varying potency; in the *British Pharmacopoeia* of 1932 a standardized preparation was included, but by that time digoxin was available, and by reason of Lewis' interest took a prominent place as a heart remedy, which it was certainly to retain. Digoxin is, however, for the most part unknown on the Continent of Europe and in America.

This monograph gives a less interesting account of strophanthin than the glycoside deserves. Of 118 pages of text, 79 are devoted to papers on the pharmacological action in animal tissues, which are so numerous that often the account becomes

catalogue; the remaining 39 pages on clinical action fail to show in what respects strophanthin is superior to digitalis, or to make any comparison with digoxin. It is significant that digoxin does not occur in the index, and is not mentioned in the text. Fraenkel's own writings provide a much more convincing case for the view that strophanthin has a useful place in medical practice, and it is unlikely that this monograph will achieve its declared aim. The English is in several places defective.

MICRO-ANALYSIS IN MEDICAL BIOCHEMISTRY

Micro-Analysis in Medical Biochemistry. By E. J. King, M.A., Ph.D. (Pp. 168. 10s. 6d.) London: J. and A. Churchill. 1946.

Micro-chemical procedures for commonly determined blood constituents, developed by Prof. E. J. King and his associates during the past ten years, have been widely adopted by chemical pathologists. The advantages of micro-methods have been fully appreciated. There is a considerable saving in reagents when an analysis can be made on 0.2 ml. of blood instead of 2 ml.—not to mention the saving of labour in making up reagents. Coagulants may be omitted and samples measured with precision in capillary blood pipettes. Micro-chemical methods are particularly useful in investigations that require the taking of frequent samples.

Hitherto details of such methods were available only in the original publications. Some of the procedures have undergone further modifications and improvements by King and his colleagues since their original descriptions. All users of these methods will, therefore, welcome the appearance of this book, in which the latest recommendations for the published procedures, and also some additional methods, are brought together. Standard procedures are also included, so that the present book forms a complete set of instructions for the execution of all the determinations commonly asked for in routine laboratory investigations.

Analyses include those for whole blood, plasma, serum, cerebrospinal fluid, faeces, urine, gastric contents, and calculi. A chapter is devoted to gastric, renal, and liver function tests. Spectroscopic procedures are described. A most useful chapter on colorimetric and photometric measurements includes details for the construction and assembly of a simple direct-reading photo-electric colorimeter. Tables of normal values and abnormalities in composition of blood, with some very sensible observations on the use of the word "normal" in this connexion, form an admirable introduction to the very lucid descriptions in the analytical chapters.

Since this is a book to buy and not to borrow, the publishers are to be congratulated on the very reasonable price.

ELECTROTHERAPY AND LIGHT THERAPY

Electrotherapy and Light Therapy. With the Essentials of Hydrotherapy and Mechanotherapy. By Richard Kovács, M.D. Fifth edition, thoroughly revised. (Pp. 694; 352 engravings and a coloured plate. 42s.) London: Henry Kimpton.

It must be twenty years since Dr. Richard Kovács produced his first edition of *Electrotherapy and Light Therapy*. The present edition is the fifth, and it comes at a most opportune time, when the whole outlook of the medical profession in relation to the techniques used in rehabilitation has undergone a profound transformation.

Dr. Kovács, in his preface, states quite correctly that in 1927 "medical men practising as electrotherapists were looked upon by many of their medical brethren with suspicion, mingled with pity." Now all this is changed and the whole profession, and indeed not only the whole profession but even Ministers of the Crown, now acknowledge the value and scope of rehabilitation methods. Dr. Kovács's several editions have always moved forward with these developments. One of the great advantages in all his writings is that he never claims a physical or electrical method as a cure-all or a 100% benefactor. The techniques are well set out and the book can either be read consecutively by the aspirant to knowledge of the subject or used as a textbook of reference. It has won for itself an honoured place which it thoroughly deserves.

It is a pity that this edition was in the press at the same time as Dr. W. S. C. Copeman's remarkable paper on fibrositis, but

it is interesting to see that Fig. 296 bears striking testimony in support of Dr. Copeman's theory. It is a pity, too, that war conditions have prevented the author from paying a visit to this country before publication, as had he been able to do so doubtless a number of the advances made during the war here, both in methods and in apparatus, would have been incorporated. In these respects the book is not fully complete for the candidate for the Physical Medicine Diploma. But these small defects in an otherwise excellent and very readable treatise will doubtless be remedied in a subsequent edition, which it is hoped will soon be on its way.

PATENT MEDICINES

Patent Medicines: An Indictment. By Hugh Linstead, M.P. (Pp. 32. 1s.) London: National News-Letter, 162, Buckingham Palace Road, S.W.1.

This is a useful and temperate statement on the position of "patent medicines" in this country, with suggestions for further reforms. Coming as it does from the Secretary of the Pharmaceutical Society of Great Britain, it carries an authority justified by the prolonged work of that body on this problem. The pamphlet has left on this reviewer the general impression that "it does move," if only slowly. Mr. Linstead says that the real "secret" remedy no longer exists, and this, it may be said, is thanks largely to the pioneer work of the B.M.A. in publishing its books on *Secret Remedies* and *More Secret Remedies*. The law now insists on publication of the formula, and this is a great check on "exaggerated claims." Mr. Linstead deals with the great difficulties of controlling the ingenuity of the advertising agent, and points out that his present efforts are mainly devoted to a subtle rousing of a sense of fear—fear of what symptoms may lead to if not abolished by the medicine the potential user is advised to take. Only those who have tackled the job of censoring such advertisements can realize the devilish ingenuity of the advertiser.

The booklet very fairly shows that the better elements of the proprietary trade, of the newspaper proprietors, and of the Advertising Association, have done much to abolish the worst evils of the business; but, as he points out, these bodies are voluntary associations and have no direct control over the outsider. An interesting point is raised both by Commander King-Hall in his preface and by Mr. Linstead—they suggest that there is something wrong in allowing advertisements which would compete with the new Health Service. The Government "cannot permit every device of modern publicity to incite the citizen to ignore a Service which the State provides for him and to accept in its place one provided by the advertiser." It is not easy to reconcile this view with the statement on page 24 which says "it is essential to preserve the right of the citizen to treat his own ailments." Thus we have the usual clash between the duty of the State and the rights of the individual. There is no blinking the fact that there is a danger to individual initiative if the citizen is not to be allowed to treat his own symptoms at his own risk because the State has provided something which *it*, but not *he*, may think better for him. However, the dangers of self-treatment are there and it is necessary to protect the public from false or exaggerated claims. Mr. Linstead, in addition to providing a careful summary of what has been done, makes several suggestions for further reforms when Parliament can find the time.

Notes on Books

The full text of Prof. G. GREY TURNER's Hunterian Oration entitled *The Hunterian Museum Yesterday and To-morrow*, which he gave last year at the Royal College of Surgeons of England, has now been published, with 43 illustrations, as a book of 92 pages by Cassell and Co., Ltd., price 15s. Many of those who read the shortened version in these columns on Feb. 24, 1945, will like to read and possess the oration *in extenso*. It is an interesting contribution to medical history, and the orator's ideas for the future are well worth pondering.

Practical Anaesthetics (2nd edition, Baillière, Tindall and Cox, 10s. 6d.), by Dr. J. ROSS MACKENZIE, shows evidence of thorough revision. In many places the text has been elucidated by the inclusion of additional matter. The book will be helpful for students, house-surgeons, and the occasional anaesthetist.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 5 1946

WORLD MEDICAL ASSOCIATION

Thirty-one countries sent representatives to the three-day conference held last week at B.M.A. House under the joint auspices of the Association Professionnelle Internationale des Médecins and the British Medical Association. Under the skilful guidance of Sir Hugh Lett, who presided throughout the three days, the conference managed to avoid the shifting sands on which so many other international projects so easily come to grief. Sir Hugh was aided in his task by the readiness of those who had done so much for the A.P.I.M. to merge their identity in the wider organization established by the conference under the comprehensive title of World Medical Association. The objects of this new Association are (1) to promote closer ties between the various international medical organizations; (2) to study the problems which confront the medical profession in different countries; (3) to organize exchange of information; and (4) to establish relations with and present the views of the medical profession to the World Health Organization and UNESCO. It was at the suggestion of Lord Horder, who attended as observer for the American Medical Association, that according to the following agreed form of words the first object was "to promote closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means available in order to assist all peoples of the world to attain the highest possible level of health." There was some discussion on whether the new Association should concern itself with scientific medicine; but the view prevailed of those who pointed out that scientific medicine was well cared for by various national societies and scientific societies. On the last day of the conference a Committee of nine was set up to work out the details of the constitution and to prepare the agenda for the next conference, which is to be held in Paris. The official languages of the World Medical Association are to be English and French. Dr. Charles Hill, Secretary of the B.M.A., and Dr. P. Cibré, of La Confédération des Syndicats Médicaux Française, were elected joint secretaries. The following Committee was appointed to prepare the ground for the next conference: J. A. Pridham, Great Britain; T. C. Routley, Canada; O. Leuch, Switzerland; F. Decourt, France; P. Glorieux, Belgium; D. Knutson, Sweden; L. G. Tornel, Spain; A. Zahor, Czechoslovakia; and I. Shawki Bey, Egypt.

It might be thought that medicine was already becoming well enough represented on the international stage through W.H.O., UNESCO, and indeed through the Food and Agricultural Organization which, under the inspiring guidance of Sir John Boyd Orr, is setting such a wholesome example to U.N.O.; but all those who attended the conference last week were left in no doubt at the end of three days' discussion about the need for a world-wide organization of medical men and women, and came away with the conviction that this new body will not be content with passing high-sounding resolutions which by their vagueness become untranslatable into action. The World Medical Association means business, and the delegates from the various countries came to London last week because they felt the need for the support of their confrères in other countries against the forces they uneasily feel to be menacing the age-old traditions and freedoms of the medical profession. Dr. F. Decourt even expressed doubt about the intentions of W.H.O. and UNESCO. Dr. Decourt indeed said one of the reasons for establishing the World Medical Association "was to defend medical practitioners whose liberty was being menaced in many countries." He was, however, assured by Dr. Chisholm who represented W.H.O., that this organization would not interfere with the medical practitioner in any country. In those valuable contacts that take place outside the official meetings it was clear that doctors from more than one country were gravely concerned about the relationship between the State and the medical profession, and were anxiously watching the developments of the medical services in this country, feeling that what happens in Great Britain may have a profound effect on the evolution of medical services in other nations. Membership of a world-wide organization will heighten the sense of responsibility of the numerous national bodies constituting it and will lend overwhelming strength to the constituent bodies when they severally have to deal with the body politic.

The World Medical Association is in its early infancy. Under the energetic direction of its English and French secretaries it will, we may feel sure, grow speedily and painlessly into a full-grown adult. Once the details of constitution have been worked out W.M.A. will no doubt get quickly on to a fact-finding investigation which will collect the data, and then contrast and compare the systems of medical organizations and administration in different countries. Dr. T. C. Routley, representing the Canadian Medical Association, said early in the proceedings that he wanted to see an organization "which would signify the unity of doctors all over the world." This also was the wish of the thirty-one nationals sitting in B.M.A. House last week. It now remains to see this unity embodied in practical and practicable terms and then to see that those things which doctors in all countries hold to be fundamental principles in professional life are preserved in this atomic age.

CANCER SCHEME FOR NORTHERN IRELAND

Northern Ireland is contemplating a Cancer Act similar to the one which became law in Great Britain in 1939. The cancer death rate in Northern Ireland has risen almost continuously during the last twenty years. No doubt the rise, there as elsewhere, is partly accounted for by the larger proportion of the middle-aged and elderly in the population, also by more precise diagnosis and death certification, but the figures have caused concern among public health authorities and in the Ministry of Health and Local Government. Recently the Ministry invited Lord Amulree, M.D., of the British Ministry of Health, Dr. Ralston Paterson, director of the Holt Radium Institute, Manchester, and Mr. G. F. Stebbing, honorary secretary of the National Radium Commission, to visit Northern Ireland, where they discussed the problem of cancer detection and treatment with Government officials, hospital authorities, and representatives of the medical profession. Many of their suggestions, based on experiences in Great Britain, have been incorporated in a memorandum on the measures to be taken to deal with cancer in Northern Ireland which has been prepared by the Health Advisory Council of the Ministry, a body of some twenty members of whom about half are medical men.

One condition which British experience suggests is that an adequate cancer service must be based on a large unit of population, not less than one million; therefore in Northern Ireland, with a population of not much more than one and a quarter million, there is room for only one cancer organization, with its headquarters obviously in Belfast. It is proposed that the British plan be followed, whereby financial responsibility for cancer schemes is placed on county and county borough councils, aided by grants from the national Exchequer. These local authorities will naturally be represented on the controlling organization, together with the Ministry, the medical profession, and the two Belfast hospitals, the Royal Victoria, and the Mater Infirmorum, where most cancer patients who come under hospital treatment are received (though it is estimated that 75% of the deaths from cancer take place in patients' homes). The centre, both for surgical and radiotherapeutic treatment, if these recommendations are followed, will be set up in the grounds of the Royal Victoria Hospital, though it will be a separate administrative unit. It will accommodate in-patients, about 50 in the radiotherapeutic department and 100 in the surgical, as a start, and it will have a dormitory annexe for out-patients from a distance who do not need admission to hospital wards. An essential part of the scheme will be diagnostic clinics at selected hospitals in various parts of the country, and it is considered that in the remotest areas no patient should have to travel more than twenty or thirty miles to reach such a clinic. Other features of the scheme will be institutional accommodation, where this is necessary, or domiciliary nursing and other aid if more appropriate, for untreatable cases, and a uniform system of records and follow-up. It is hoped to establish co-operation with the Belfast Medical School with a view to courses of undergraduate and postgraduate instruction in the diagnosis and treatment of cancer; with Queen's

University with a view to the institution of cancer research; and with organizations in Great Britain, especially the National Radium Commission. The charter of the Commission does not cover Northern Ireland, and it is suggested that an amendment might be sought in that respect and that it might be possible for Northern Ireland to hire radium from the Commission instead of making fresh purchases.

To organize the entire diagnostic and treatment service a whole-time chief officer would be appointed. This officer, it is thought, should be a radiotherapist with extensive experience in that specialty, as well as some experience in surgery. A staff of whole-time officers would be attached to the radiotherapy department. For the surgical department there would be a panel of consultants holding part-time posts, with junior whole-time officers acting under their direction. The responsibility of the general practitioner in the detection of cancer is strongly emphasized in the memorandum. It is fully appreciated that the success of the scheme will largely depend upon his equipment and vigilance, and the Advisory Council stresses that there is nothing in its recommendations which is intended to imply that any duties of the general practitioner should be taken out of his hands. Through the Northern Ireland Branch of the British Medical Association practitioners will be represented on the controlling body, and immediate steps are proposed for postgraduate training, in which, it is suggested, experts from Great Britain might be invited to come over and assist.

The full development of the scheme, which, of course, will call for legislation, may take a couple of years and may possibly be delayed until it can form part of the framework of a National Health Service for Northern Ireland. Meanwhile some temporary arrangements are proposed whereby a certain number of staff may be recruited, diagnostic clinics set up, special provision be made at some Belfast hospitals for cancer treatment by means of surgery, and cases which need radiotherapy may be concentrated for the time being in the emergency hospital at Musgrave Park. The memorandum strikes a note of urgency, and this is echoed in a foreword by the Minister of Health and Local Government himself, who urges the medical profession, hospital managements, and local authorities to lose no time in making a unified and concentrated attack on a disease which is second only to heart diseases among the principal causes of death.

THE MIASM OF MARASMUS

Apparently as a reflection of an increased incidence of enteritis in the general population, diarrhoea in mothers and babies has of late been observed in the lying-in wards of several hospitals in this country. A typical outbreak described by Brown, Crawford, and Stent¹ was referred to in an annotation² under the title of "What is Gastric Flu?" This epidemic appeared in the general and maternity wards in a thousand-bedded hospital serving a large borough in May, 1945, and the facts are worth review. During a 15-week period 20 patients were found to have had diarrhoea on admission, and 91 persons, inclu-

¹ *British Medical Journal* 1945, 2, 524.

² *Ibid.*, 1946, 1, 459.

ding 27 nurses and 25 babies, developed watery diarrhoea apparently contracted in the hospital itself. Vomiting occurred in 46 of the total of 111 cases, and pyrexia was present in 32 of the 89 adults but not in the babies. Twenty-five of the adults had nausea. The pattern of the incidence was that of a chain outbreak passing from two patients admitted to a surgical ward with suspected abdominal emergencies, through, in turn, a ward maid, a nurse, babies, mothers, medical officer. There were no significant bacteriological findings except that, in the fourth and fifth weeks, *B. dysenteriae* (Sonne) was recovered from fourteen of twenty cases of diarrhoea in one general ward and appeared to be an intercurrent infection affecting this ward only.

An inquiry by questionnaire of the practitioners in the borough showed that the disease, which they considered to be a new phenomenon clinically distinct from bacillary dysentery, had been widespread among the adult population; that it was characterized by sudden onset of profuse watery diarrhoea; that the outbreak had started insidiously; and that there had been two or three waves in April, May, and June, 1945. No deaths were reported. The description of this outbreak corresponds closely with that of the "viroid dysentery" of Reimann *et al.*,³ which had been transmitted to human volunteers by inhalation of nasopharyngeal washings and faecal filtrates. The epidemic was instructive because: (1) The maternity unit at the hospital contained 66 beds and 66 cots in 3 wards, yet one of these escaped entirely, although in the 2 adjacent wards and nurseries 65 persons were involved. (2) All babies were breast-fed, apart from sterile water given with sterile precautions, yet on numerous occasions mothers only or babies only were affected; if both, babies showed signs before mothers, on an average 4.4 days earlier. (3) The outbreak terminated spontaneously without closure of the maternity unit. (4) It in no way resembled in severity a previous epidemic of neo-natal diarrhoea at the same hospital a few months before, when the mothers had escaped. Although a comparison was made both in Brown's paper and in the previous annotation² between the condition and the epidemic nausea and vomiting described by Bradley,⁴ further experience suggests that this condition of watery diarrhoea is distinguishable clinically and epidemiologically from the latter disorder.

We are now informed that in some of the 1946 outbreaks of this apparently novel condition of watery diarrhoea in mothers and babies there has been an appreciable mortality among the infants: in one lying-in hospital 12 of 77 affected babies died. The characteristic orange-coloured stools of the "epidemic diarrhoea of the newborn" described by Ormiston⁵ have not been observed. There has been no evidence of the common respiratory or pyogenic infections in the recent outbreaks, and the diagnosis of parenteral enteritis could not be applied. Sulphonamides were ineffective, but several of the fatal cases showed a biphasic course: after the initial loss of weight and diarrhoea the babies improved until, comparatively suddenly, they collapsed and died. This biphasic course, which may also exist in parenteral enteritis, is referred to by High, Anderson, and Nelson.⁶ They had previously discussed therapy, in particular the correction of acidosis and maintenance of fluid balance (Anderson, Nelson⁷), but they now report less favourable results. They complain about the difficulty of establishing the diagnosis of "epidemic diarrhoea of the newborn" in the initial cases of an outbreak. This experience is shared by others,

and for that reason we should err on the side of safe and treat every infant with diarrhoea, or in fact sudden loss of weight, as infectious. There is another difficulty of diagnosis: it looks as if there were many clinical entities of different aetiology, causing outbreaks of neo-natal diarrhoea. Until the tangle has been unravelled observation should record complete descriptions of all the clinical and epidemiological features of an outbreak. By itself, the term "diarrhoea of the newborn" has little more meaning than "marasmus," or "atrophy," or "decline," or our concept of the cause or causes is not appreciably removed from the "miasm" stage. Systematic observation and record offer the most speedy escape from the present confusion.

PENICILLIN TREATMENT OF MENINGITIS

The treatment of meningitis is technically the most difficult sphere of penicillin therapeutics, and for obvious reasons few extensive studies have been made of it. The largest series of published cases is that described by a distinguished team of investigators at Philadelphia—W. I. White, F. D. Murphy, J. S. Lockwood, and H. F. Flippin—and comprises 71 cases, of which 50 were pneumococcal. The mortality among the latter was 64%, which, as the authors remark, does not appear to represent much improvement on the results of earlier methods of treatment. Unfavourable factors were advanced age—of 17 patients over 50 years old 15 died—and the continued existence of an uncontrolled focus in the ear or elsewhere from which the meningococcal infection originated. This series included patients—evidently treated in early days, when penicillin was scarce—who received doses which would now be considered inadequate. Seven of these patients, and 7 out of 12 cases of meningococcal meningitis, received penicillin by the intramuscular or intravenous route only and not intrathecally.

Since this paper was published it has become recognized that intrathecal injection is an imperative necessity; penicillin, unlike sulphonamides, does not pass into the cerebrospinal fluid from the blood in anything like sufficient concentration. That this is true of the normal meninges has been accepted for some time. W. McDermott and R. A. Nelson² examined the cerebrospinal fluid of 7 patients after the intramuscular injection of penicillin and found only a trace after an enormous dose had been given. Ordinary doses not appearing in the fluid at all. Such doubt as there has been has resulted from the statement that the existence of a meningitis enables the penetration of penicillin into the cerebrospinal fluid to take place: this has been asserted by several authors, and a few successful results have been claimed in the treatment of meningitis by intramuscular injections of penicillin alone. The truth in this matter seems to have been finally settled by J. A. Kinsman and C. A. d'Alonzo.³ These authors, after again demonstrating that in patients without meningitis no penicillin reached the meninges after intramuscular injection, tested the effect in meningitis by using this method of treatment in 9 patients with cerebrospinal fever. This bold step was rewarded by affording a clear answer: there was transitory improvement, due doubtless to the effect on an accompanying bacteraemia, but the signs of meningitis were unaffected. The temperature rose again within 24 hours, and the cerebrospinal fluid still contained as many cells as before together with living meningococci, and never more than a trace of penicillin. Sulphadiazine was then brought to the rescue and all was well.

³ *J. Amer. med. Ass.*, 1945, 127, 1.

⁴ *British Medical Journal*, 1943, 1, 309.

⁵ *Lancet*, 1941, 2, 533.

⁶ *J. Pediatr.*, 1946, 23, 407.

⁷ *Ibid.*, 1944, 25, 319.

¹ *Amer. J. med. Sci.*, 1945, 210, 1.

² *Amer. J. Syph.*, 1945, 29, 403.

³ *New Engl. J. Med.*, 1946, 234, 459.

The logical way of regarding this question is that meningitis has no effect on the permeability of the blood-brain barrier in the ordinary sense; such penicillin as reaches the cerebrospinal fluid in meningitis is simply that contained in the exudate itself. The much higher concentrations attainable by intrathecal injection persist, after an adequate dose, for 12 or even 24 hours, and are sufficient to control not only all coccal infections but even meningitis due to such a comparatively resistant organism as *H. influenzae*. This expectation is at least justified on theoretical grounds, and the single case of *H. influenzae* meningitis described in this *Journal* by McIntosh and Drysdale⁴ affords it some support. Those seeking detailed information about the technique of treating meningitis with penicillin should consult the classical papers of Cairns and his colleagues^{5,6}; they deal with pneumococcal infections, but the methods advocated apply equally to other forms. These authors' results were considerably better than those obtained in Philadelphia: of 38 patients only 9 died, and 4 of these were moribund on admission. In the later cases of this series penicillin was given intramuscularly as well as intrathecally, and sulphadiazine was given in addition. The lumbar route for intrathecal injection was found satisfactory in most cases, and an important feature of this study was the demonstration that penicillin diffuses along the cerebrospinal fluid pathways with extraordinary facility, even reaching the lateral ventricles from the lumbar region. Occasionally, when obstruction exists, cisternal or intraventricular injection may be necessary. The strictest asepsis is imperative: nowhere can penicillin-resistant contaminants in the shape of coliform bacilli do such damage as in the meninges. For these and other reasons, the penicillin treatment of meningitis must remain a serious undertaking, calling for first-class hospital facilities or their equivalent.

WORKING CONDITIONS IN AUSTRALIAN TEXTILE MILLS

The working conditions in Australian textile mills are liable to be much more trying than those experienced in this country, and Bulletin No. 7 of the Industrial Welfare Division of the Australian Department of National Service⁷ describes these conditions at length, and suggests the most suitable remedies. The Australian climate differs greatly from area to area, and though there is little difficulty in obtaining fairly comfortable working conditions in a temperate climate such as Hobart, it is very different in Sydney and Adelaide. It is well known that the mechanical ease of the spinning process improves as the temperature and relative humidity of the air are increased, but unfortunately such increments—if beyond a moderate limit—become more and more trying to the operatives, so much so that the efficiency of their production is seriously impaired. In Australia some 50,000 textile workers are employed, many of them in old mills with obsolete plant, and in the face of world competition it is vital that they should be replaced by the best types of mill. Some of these mills already exist in Melbourne, Sydney, and elsewhere, and they are described at length in this Bulletin, with many excellent photographic reproductions. Series of tests on atmospheric working conditions were carried out in 67 mills over a fifteen-month period, and especially during the hot months of December to March. It was shown that the effects of solar radiation could be greatly reduced by improving the insulation of the buildings, a fall of

as much as 10° F. in the temperature of the mill, being thereby brought about. The effects of better natural and mechanical ventilation are debated, but it is admitted that on many days of the year tolerable working conditions in some towns can be obtained only by the installation of expensive air-conditioning plants. Series of charts are given showing the number of days on which the mill climate in various towns can be expected to exceed (i) the normal limits for efficient human work, and (ii) the limits which can barely be tolerated.

BUTTERCUPS AND ANTIBIOTICS

Since the discovery that penicillin can be obtained from moulds such as *Penicillium notatum*, similar therapeutic agents have been sought in other fungi and bacteria. This search for new antibiotics¹ has included the higher plants in its scope. Osborn² examined 2,300 species belonging to 166 families by methods similar to those used in the estimation of penicillin, and he found substances inhibiting the growth of *Bact. coli* and *Staph. aureus* in 63 different genera. The most active substances were obtained from plants of the Ranunculaceae family, especially anemone, clematis, hellebore, and ranunculus. Lucas and Lewis³ reported antibacterial principles, varying greatly in their potency and distribution, in the leaves of Scotch thistles, of verbascum, and of peonies, and in the fruits of plants of the rose, saxifrage, and other families. In particular, a species of honeysuckle, *Lonicera tatarica*, was found to contain a potent principle which inhibits the growth of *Staph. aureus* and *Bact. coli*, and another which suppresses coliform bacilli but not Gram-positive organisms. According to Seegal and Holden^{4,5} extracts of buttercups and of *Anemone pulsatilla* showed activity against Gram-positive and Gram-negative bacteria, and against acid-fast bacilli.

Protoanemonin

The active principle in *A. pulsatilla* is protoanemonin. This substance inhibits the growth of *Staph. aureus*, *Bact. coli*, and *Candida albicans*, after incubation at 37° C. for eighteen hours, in dilutions of 1:30,000 to 1:100,000. Protoanemonin appears to be another member of the group of antibacterial agents which includes crepin, penicillic acid, and clavacin, all of which contain a 5-membered unsaturated lactone ring and a highly reactive double-bond system. No information is given about the toxicity of the new compound, so its possible therapeutic value is not indicated. However, judging by clavacin, its antibacterial action will probably be of more academic than clinical interest. But if a practical use were found for it, it would be pleasant to think that the anemones and buttercups which beautify our woods and fields in spring might also cure some of the sickness prevalent at that season.

The Medical Research Council has recently received from Maj.-Gen. Sir Leonard Rogers, K.C.S.I., F.R.S., late I.M.S., a further generous addition to the endowment for research in tropical medicine with which he originally entrusted the Council in 1926. The capital value of the fund thus created is now approximately £15,000. The income is applicable to special purposes within the general field of tropical medical research.

THE BÜRGERSPITAL BASLE

A LANDMARK IN MUNI- HOSPITAL BUILDING

Few people who attended the Swiss Conference in Basle a few years ago could fail to be impressed by the new hospital which was opened last year. Here, so far as a quick glance allowed one to judge, was a building which in its appearance, construction, and facilities for patient, doctor, and cook approached the ideal. A few illustrations reproduced will give the reader some idea of its layout.

When the University of Basle was founded in 1460 instruction in medicine was begun on a modest scale; although in those days the sick were for the most part cared for at home there was some clinical instruction at the bedside in the Basle hospital. Already at the beginning of the 16th century the town had two hospitals; in 1260 another hospital was built which continued in use until 1842.

In that year reconstruction of the old and the erection of new hospital buildings were undertaken. The new building consisted of a hospital for the sick, a mental hospital, and an institution for the aged, comprising in all 332 beds. The population of Basle being at that time 26,300. The population rose to 43,540 in 1865 and in 1944 was 172,000. The number of medical students in 1842 was 19 and 562 in 1944. The growth of the town, the advance of medicine, and the increase in the number of students necessitated further building. The pressure on beds and services was relieved by the establishment of a children's hospital, an eye hospital, a women's hospital, and a mental institution. At the same time a number of private hospitals made their appearance. But the need for further extension of hospital facilities soon made itself felt.

The Basle authorities considered the possibility of finding a new site for the municipal hospital building, but a proposal to the effect was rejected in 1935, and a year later it was decided to embark upon a new project of reconstruction. The provisional plans were worked out by 1937 and work on the new building—illustrated in this article—began in 1940.

The Bürgerspital, or

municipal hospital, is situated in a densely populated part of the town and is easily available for patients. The town authorities agreed to divert heavy traffic from the street the new hospital faces so that the patients should not be subjected to too much noise. The hospital extends approximately from west to east in its length. The horizontal building facing the Spitalstrasse, in the middle of which is the main entrance, has in its west wing the surgical polyclinic, and in the east wing the medical clinic. On either side of the entrance are two lecture theatres with glass roofs. The two clinics and the entrance hall are connected with the ward block that lies immediately south, the windows of which face south-south-west. The wards are grouped similarly to the clinics, with the medical wards on the west side and the surgical on the east. The ward block rises higher than the frontage section and the wards are arranged in the seven floors above ground level composing it. Finally there is an extensive roof terrace from which one gets magnificent views of the Vosges and Jura Mountains and the Black Forest. Part of the roof terrace is partitioned off by glass for the shelter of resting patients. The extension from the west end of the frontage houses the kitchens and living-rooms for nurses and other staff. Extending to the south of the wards and from the west angle is a block for infectious diseases. The first basement floor houses the x-ray department and the department for physical therapy; here also is a section for the treatment of emergency cases. In the second floor below ground there is a swimming-pool. In other parts of the building there are pharmacological and pathological departments, and so forth.

In the Bürgerspital no ward contains more than six beds (see illustration). The wards are arranged in units of 16 beds—that is, two wards containing six beds each and on either side two wards containing two beds each. This unit of 16 beds is looked after by a nurse, an assistant nurse, and a probationer. The four wards comprising this unit have intercommunicating doors. These ward units are further grouped into a *Krankenstation* of three such units with an additional two-bedded ward, making in all 50 beds. Altogether there are 671 beds in the main ward block—the *Krankenhaus*. The wards are classified as first-class, second-class and third-class. The "first-class" wards

FIG. 4.—Bird's-eye view, showing ward block to south of main entrance building.

FIG. 5.—A public ward of 6 beds.

FIG. 6.—The Entrance Hall.

on the top floor are single-bedded rooms; on the floor beneath (6th floor) there are two beds to a room, and the third-class wards, comprising six beds each, occupy the first four floors.

There is not the space here to discuss the numerous details of construction, intelligent use of material, heating and cooling systems, methods of delivering meals at their proper temperature to the patients in the wards, etc. It seems as if every conceivable device that could contribute to the comfort and safety of the patient and to the efficient working of the hospital for doctor and nurse had been worked to the finest point of detail. The only point of criticism is that the medical staff appear to have fair distances to walk from one part of the hospital to another, and for the relief of the eye one would have thought that more use could be made of colour on the internal walls.

BRITISH-SWISS MEDICAL CONFERENCE

Concluding Sessions

It remains to refer, all too briefly, to some of the later communications made to the Basle Conference. Several of these were by Swiss specialists. A description of twenty years' research in typhus fever was given by Dr. HERMANN MOOSER (Zurich). Formerly, he said, typhus fever was regarded as a well-defined morbid entity in its epidemiology. Then doubts were raised about the louse being the sole vector. A new variety of typhus was found in Mexico and parts of the United States which was called murine (appertaining to the mouse) typhus which, although it showed cross-immunity with classical Old World typhus, could clearly be distinguished from it by its different course in laboratory animals. He related the results of observations on strains of murine typhus which had laid the foundations of most of the present knowledge of the epidemiology of rickettsial diseases.

Prof. HUGO KRAYENBÜHL (Zurich) discussed the immediate and late results of carotid ligation of intracranial aneurysms. He gave a review of 35 cases, and concluded that, while with infraclinoid aneurysms carotid ligation was a safe procedure, it was not highly dangerous, as some had claimed, in supraclinoid aneurysms; his seven cases had tolerated the ligation wholly without complications.

The regulation of lung volume was discussed by Prof. FRITZ VERZAR (Basle), with emphasis on a new feature of respiration, namely, the increase of the respiratory surface area resulting from an increase in lung volume in hyperventilation. The final Swiss paper was by Prof. P. H. ROSSIER (Zurich) on thromboangiitis obliterans. Postmortem examinations of persons who had died of this disease had shown that the coronary arteries were affected as frequently as the vessels of the lower limbs, and about half of the patients died from coronary occlusion.

Nuclear Physics and Medicine

A paper which broke much fresh ground was read by Dr. J. S. MITCHELL (Department of Radiotherapeutics, Cambridge). He had much of interest to say on metabolic disturbances produced by therapeutic doses of α and gamma radiation, on the production of gene mutations and chromosome breakage, and on clinical problems such as the relation between dosage and permanency of cure of malignancy, and dosage rate and significance of indirect effects, in radiotherapy. The part of his paper which excited most attention was that concerning the biological application of the recent advances in nuclear physics which had led to the atomic bomb. These provided a new powerful method of preparing radioactive isotopes, which are becoming widely used in medicine as tracers for the study of metabolic processes, as artificial gamma ray sources in radiotherapy, and in extension of this, some could be used internally, by taking advantage of their selective absorption by tissues—e.g., iodine by the thyroid gland—to reduce secretion or cell division by local irradiation. He also spoke of the possibilities of fast neutron beams with which previous clinical trials could not be regarded as final because of the difficulties of absolute dosimetry and the inevitable restriction to patients with advanced disease. Evidence was accumulating to indicate differences in the mechanism of the biological action of fast neutrons and gamma radiation, though at present it was difficult to know whether any of these differences were likely

to prove advantageous in therapeutics. There was no alternative to the cyclotron in this field as the neutron energies produced in the "pile" were not sufficiently high for the treatment of deeply situated malignant tumours.

Prof. A. C. FRAZER (Birmingham) discussed fat absorption in the light of the current partition hypothesis and referred their host Prof. Verzár as an authority. Investigations show that in the intestinal lumen emulsification down to 0.5 μ part is largely due to the triple complex fatty acid bile salt monoglyceride, two components of which result from lipolysis which process is often self limiting by local fall in pH as its released fatty acids are removed in virtue of their water solubility.

Emulsified unhydrolysed fat particles, smaller than water-soluble fatty acids *per se*, and the longer chain fat soaps, can be passed, markedly influenced by corticosteroid salt, and the phosphorylation mechanism, through the strict border of the intestinal lining cell. Within the intestinal resynthesis of fat and phospholipidogenesis occur and, with choline, facilitate the further absorption into the blood stream. Distribution in the body, independent of the total quantity ingested, varies with extent of hydrolysis, triglycerides tend to travel by lymph stream to the body fat deposits and hydrolysates via portal venous blood to the liver.

In man, fat-balance experiments, repeated intestinal withdrawals, and blood chylomicron counts are of value in assessing, as yet incompletely, the fat absorption defects of sprue, pancreatitis, regional ileitis, biliary obstruction, gas colic fistula, and gastrectomy.

Dr. R. R. RACE (London) presented an interesting paper on the Rh blood groups and on his collaborator Prof. R. FISHER's hypothesis on the inheritance of the Rh genes, which had now brought order out of chaos. So far eight hereditary forms of Rh⁺ had been isolated, the eighth being discovered after Fisher postulated that it must exist.

Chemotherapeutic Control of Malaria

The whole subject of the chemotherapeutic control of malaria in war and peace was reviewed by Dr. HAMILTON FAIR (London). In war the main problem was one of a non-immune population at risk in a highly malarious area, where the question of chemotherapeutic interference with premunity was not involved. In peace the control of malaria was more concerned with communities which had acquired a varying degree of premunity as a result of exposure over prolonged periods to repeated infections with different species of parasite—a condition generally found in indigenous populations residing in hyperendemic or highly malarious areas. In recent war there was a world shortage of antimalarial drugs and such research stimuli as a malaria casualty rate of 74 per annum (later reduced to about 30%) among Australian troops in New Guinea. Dr. Fairley went on to describe results obtained in a medical research unit in Northern Australia where 850 volunteers were experimentally infected with sporozoite-transmitted malaria while taking different antimalarial drugs and he discussed the action of these, dividing them into schizonticidal suppressants (e.g., quinine, sulphadiazine, atabrine); causal prophylactics (e.g., plasmoquine, paludrine). He spoke in particular of paludrine as outstanding in that a single dose of 50–100 mg. given from 48 to 120 hours after exposure was causal prophylactic for *P. falciparum* infections, and similar single dose of 100 mg. would resolve an overt attack of *P. falciparum* malaria through schizonticidal action. The 100 mg. taken twice weekly promised to be a complete suppressant.

"The possibilities of this single dose regimen of paludrine apply to native villages and epidemics in hyperendemic areas open up an entirely new field in the chemotherapeutic control of this disease, not only on account of its schizonticidal value, but also because of its extraordinary potency as a causal prophylactic. . . . The discovery of paludrine and the increased control of the mosquito vector of its larvae by D.D.T. and other means should enable future epidemics to be rapidly controlled."

The subject of arterial injuries was dealt with by Mr. J. MASON-BROWN (Edinburgh). He described 62 operations for traumatic aneurysm, of which 23 were emergencies treated in 20 cases by ligation and 3 by suture. One death followed proximal ligation of the common iliac artery for a huge false

Controlling the asthmatic spasm

In asthma and other allergic disorders no treatment for the attack has yet disturbed the pre-eminence of adrenaline, the physiologically specific, natural inhibitor of those disorders; but, when the attacks are frequent and of considerable duration, the use of the hydrochloride has the disadvantage of making frequent injections necessary, owing to its relatively transient effect.

With the introduction of **Hyperduric** ADRENALINE this troublesome frequency of injection has been overcome by the combination of the active base with mucic acid (the distinctive feature of the Hyperduric series) and the action of the resulting adrenaline mucate is observable for 8 to 10 hours.

THE CHOICE OF A SULPHONAMIDE

For the treatment of bacterial infections the sulphonamide preferred is one of high antibacterial activity, by means of which therapeutic blood levels can be rapidly achieved and easily maintained, with minimal toxic manifestations.

These desiderata are to be found in 'Sulphamezathine', a new sulphonamide which many authorities consider to be the drug of choice for use in pneumonia, meningitis, haemolytic streptococcal infections and *Bact. coli* infections of the urinary tract.

Highly efficient therapeutically, 'Sulphamezathine' is well tolerated and has little tendency to produce unpleasant effects such as nausea, vomiting or cyanosis. By reason of its ready solubility, renal complications are rarely encountered—a decided advantage over many sulphonamides.

Powder: Containers of 25 grammes, 100 grammes and 500 grammes.

Tablets: 0.5 gramme: Containers of 25, 100 and 500.

Ampoules: 1 gramme (in 3 c.c.): boxes of 6 and 25.
3 grammes (in 9 c.c.): boxes of 5 and 25.

Literature will be forwarded on request.

ANAHÆMIN B.D.H.

*The Erythropoietic Fraction of Liver
Described by Dakin and West*

The principal indication for Anahæmin B.D.H. is the treatment of pernicious anæmia. It is highly effective also in preventing the onset of subacute combined degeneration of the cord as well as in correcting all the remediable symptoms of this syndrome if it has become established.

A third important application of Anahæmin B.D.H. is for the treatment of debility, diminished vigour and undue 'fatiguability'. Details of treatment will be gladly supplied on request.

DEPRESSION

The following instances of simple depression are familiar to every physician:

1. Depression following acute infectious diseases, typically influenza.
2. Post-partum and post-operative depression.
3. Depression accompanying the menopause in women and the involutional period in men.
4. Depression associated with menstrual dysfunction.
5. Reactive depression precipitated by an external problem situation which the patient cannot resolve, tolerate or ignore.

In all such cases 'Benzedrine' therapy may be expected to help reawaken mental alertness and optimism and to restore the savour and zest of life.

'BENZEDRINE' TABLETS

Each tablet contains 5 mg. amphetamine sulphate. Samples and literature on request.

f the external iliac. In one case there was slightly decreased blood supply in an already ischaemic limb, but otherwise there were no complications. In the 39 operations of election, 23 by ligation and 12 by suture, there was one recurrence in an early case of separative ligation of an axillary arterio-venous fistula. There was good evidence that following arterial suture the related vessels remained patent, and arteriograms taken in three cases of popliteal arterial suture confirmed this. One allied officer actually discharged himself from hospital after a popliteal suture, and fought with such distinction at Cassino that he was awarded his country's highest decoration for bravery.

Social and Industrial Medicine

Prof. CHARLES McNEIL (Edinburgh) read a paper on child life and health which had a medico-political tinge when he declared that in the family the mother ought to be the sovereign power, and her rule almost absolute, but the State, even the democratic State, was beginning to assert itself more firmly, and there were the makings of a conflict between the State and the family.

"The encroachment of the State in the whole life and government of the family must reduce and weaken the responsibility of the mother for the health of her children; and loss of responsibility is likely to be accompanied by a loss of her authority. The crucial question is whether it will or will not promote child health. It may produce healthier bodies. It already has produced better trained minds. It is very doubtful if it will produce more stable and happy personalities. And of these three parts of child health, the greatest is the health of the soul."

The research carried on in Great Britain in problems of industrial health, notwithstanding the difficulties imposed by total war, was related by Dr. DONALD HUNTER (London Hospital) at a special meeting of the Conference held at Rheinfelden Spa. He described work done on factory lighting and ventilation, vocational psychology, prevention of injury, toxicological investigation, industrial lung diseases, and the various new experiences afforded by wartime conditions of employment. Fluorine compounds were particularly interesting, as in one aluminium factory handling *cryolite* some 800 tons a year, much of which was in particulate form and settled on the surrounding fields, were lost to the air. Sheep and cows developed dental fluorosis with gross irregularity of teeth, and some of them died from inanition because of their inability to eat grass. An extensive investigation, not yet complete, of the factory employees and the local residents demonstrated skeletal fluorosis in 28 out of 264 furnace-men examined, but the condition caused no disability even in a man who had been exposed for over 40 years. Blood counts showed no abnormality. The water supply of the neighbourhood contained less than 0.2 parts per million of fluorine.

Surgical Rehabilitation

At a meeting of the Swiss Academy—not technically a part of the Conference—Sir REGINALD WATSON-JONES (London Hospital) gave an account, with cinematograph illustrations, of the work done in this country on surgical rehabilitation. In his story of the orthopaedic service of the R.A.F. he showed what had been done in cases with apparently hopelessly smashed limbs, and he proved by pictures of the victims after their recovery how successful the work of rehabilitation had been. Many of the young fellows who had sustained crash landings had had fractures at many levels—the fractures numbered sometimes as many as 16 or 18—yet in case after case the same boy a year later was shown in perfectly healthy trim, engaging in vigorous exercises, and apparently all the tougher for his experience. In addition to the fractures there were often severe abdominal and other injuries. He showed a photograph of two fellows who had not a single uninjured limb between them. Entirely new complications of injuries presented themselves. But very many of the men returned to non-operational flying within a year and to operational flying within eighteen months. An analysis of 1,058 cases of fractured spine showed that 914 went back to duty. One photograph showed a number of these men who had had fractured spines engaged in a tug-of-war, having provided from their own musculature something better, said Sir Reginald, than any surgical instrument-maker could provide for them.

These changes, he pointed out, were due to three things—good surgery, good rehabilitation, and good resettlement. The last was as important as the first and second. The old way of resettlement was a financial adjustment in the county court; the new way, through the Disabled Persons Act. Everything must be done to influence the minds of these men in the direction of full restoration. The surgeon should be careful of the words he used in their presence, for in their hours of enforced idleness they were apt to brood over them and possibly to get depressed. Physical exercises were no more than a part of the technique. The important thing was the extent to which the mind of the patient was influenced in the right direction.

An interesting morning was spent by the members of the Conference on visiting the several important chemical factories of Basle. Basle for the past hundred years has been the centre of a chemical industry known all over the world. To have been the birthplace of D.D.T. is its latest claim.

"WORLD MEDICAL ASSOCIATION" CONSTITUTED

INTERNATIONAL CONFERENCE IN LONDON

Thirty-three medical associations in thirty-one countries were represented at a three-day Conference held at the B.M.A. House in London, opening on Sept. 25. The Conference was under the joint auspices of the Association Professionnelle Internationale des Médecins and the British Medical Association, and its general agenda were to discuss the objects of international liaison, the setting up of an international body for the achievement of such objects, and the constitution and immediate programme of such organization. It was unanimously agreed that such an association be constituted, to take the place of the old A.P.I.M., with the objects of promoting closer ties between the various national medical organizations, of studying the problems which engage the profession in different countries, of organizing exchanges of information, and of establishing relations with, and presenting the views of the profession to, the new World Health Organization and U.N.E.S.C.O. The Conference was attended by about 43 full delegates and 32 observers.

It was agreed that the title of the new body should be the "World Medical Association," and an acting committee was set up comprising representatives from Great Britain, Canada, Switzerland, France, Belgium, Sweden, Spain, Czechoslovakia, and Egypt.

Sir HUGH LETT, Bt., President of the B.M.A., who took the chair at the conference, extended a welcome to the visitors and mentioned with special pleasure the presence of a representative (Dr. Chisholm) of the World Health Organization. The B.M.A., he said, had always taken an interest in international co-operation. One of its present activities was the arrangement of visits of lecturers to the Continent where such visits were desired, and it was also launching an abstracting service which would cover world medical literature.

Objects of an International Body

On the proposition of Dr. ALFRED CON (B.M.A.), seconded by Dr. F. MORAN (Irish Free State Medical Union), and supported by delegates from the National Medical Chamber of Poland, the General Council of Colleges of Spanish Doctors, and the Svenska Läkaresällskapet, it was agreed unanimously:

That this Conference express the view that there should be an international organization of medical associations.

A long discussion then took place on the objects of such a body, in particular whether these should be limited to professional and social medicine or should be extended to embrace scientific matters. Dr. J. C. MICHAELSON (Palestine Jewish Association) suggested two functions which such an organization could discharge. One would be to act as a clearing house for the resettlement of refugee doctors. In Great Britain since 1933 between 400 and 500 Jewish refugee doctors had been absorbed, and in America about 5,000 refugee doctors, of whom 2,000 were non-Jewish. Such an organization might make an

inventory of the number of refugee doctors in each country and smooth the absorption rate throughout the world. The other function would be to act as a safeguard against the violation of professional ethics by political doctrinaires and to resist political pressure of every description.

The Polish delegate wanted scientific medicine included among the objects of the new organization. Dr. P. GLORIEUX (La Fédération Médicale Belge) did not see how an international organization could successfully operate in this field. Adequate organizations for dealing with scientific matters, he said, already existed in the several countries. Dr. P. CIBRIE (La Confédération des Syndicats Médicaux Française) was of the same opinion. Every country had its academies. There was more need for an international organization to study the professional problems of the private practitioner, especially in view of the social security legislation which had been passed or was pending in many states. Dr. F. DECOURT (Secretary, A.P.I.M.) also considered that scientific medicine was sufficiently well served. The aim of an international organization should be to defend the rights of the ordinary practitioner and also of his patients—perhaps to defend them from the designs of their respective governments. A similar view was expressed by Greek and Dutch delegates.

The World Health Organization

Dr. T. C. ROUTLEY (Canadian Medical Association) said that he had recently attended in New York the meeting of 213 delegates from 62 countries who in five weeks had worked out the basis of the World Health Organization.¹ In his opinion the World Health Organization had the opportunity of going a long way towards solving the future problems of the world, but without the medical profession it would be like an electric grid without current. No parliament or national government would do anything with this instrument unless the doctors in every country in the world made it alive. Therefore there was now room in the United Nations for a movement among the combined medical associations parallel with that which had resulted in the World Health Organization. He had no quarrel with the old A.P.I.M., but in the sweeping movement of world events it was no longer adequate. He wanted to see an organization which would signify the unity of doctors all over the world; it should know no geographical boundaries, and should have as its primary objective to assist mankind to attain the highest possible level of health.

After some further remarks from Spanish, Portuguese, and Palestine Arab delegates acclaiming the idea of closer ties between the national medical organizations, Dr. J. A. PRIDHAM (B.M.A.) said that whatever statement of objects was adopted, it ought not to exclude the possibility at some future time of extension into other fields. The B.M.A., he said, undertook scientific as well as medico-political work, and in its scientific work it did not compete with the colleges and academies; on the contrary, these bodies were quite anxious to come into contact with the Association. If the new medical organization were the medical counterpart of the World Health Organization it would be rendering an important and useful service.

The Search for a Formula

Suggestions were made by the British, Canadian, French, Egyptian, and Palestine Jewish delegates for formulae expressing the objects of the new body, and the following form of words was eventually agreed to:

"To promote closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means available in order to assist all peoples of the world to attain the highest possible level of health; to study the professional problems which confront the profession; to organize an exchange of information on matters of interest to the profession, and to establish relations with, and to present the views of the medical profession to, the World Health Organization and the United Nations Educational, Scientific, and Cultural Organization."

Lord HORDER, who attended the conference as an observer for the American Medical Association, said that it was important to bear in mind that any international medical organization which was set up with some degree of permanency, whether inside larger organizations such as W.H.O. or U.N.E.S.C.O.,

or having its own autonomy, should put in the forefront of its objects the promotion of closer ties among the several national medical organizations. It was at his suggestion that this was placed first among the objects.

Dr. CIBRIE (France) said that in his country there was some suspicion of the World Health Organization and of U.N.E.S.C.O.—suspicion which had arisen, he thought, because these bodies had not clearly stated their aims. If it was decided to co-operate with these institutions it should be determined in advance how far that co-operation ought to extend. If the World Health Organization assumed bureaucratic functions, would they still be prepared to co-operate? Prof. GRZYBOWSKI (Poland) contested the implication that the World Health Organization would associate itself with anything which was not in the best interests of the profession. Dr. F. DECOURT, however, supported his countryman. One of the reasons for the establishment of their own body, he said, was to defend medical practitioners whose liberty was being menaced in many countries, and to proclaim in advance co-operation with this new official institution, unless such co-operation were strictly conditioned, would be unwise.

Dr. T. C. ROUTLEY (Canada), as one who had been present at the birth of the World Health Organization, said that he entertained no fears of its intrusion into political affairs affecting the doctor in any part of the world.

Eventually the phrase was agreed to "to establish relations with, and to present the views of the medical profession to, the World Health Organization and U.N.E.S.C.O."

Dr. CHISHOLM, representing the United Nations Organization at the Conference, gave an account of the World Health Organization and its origin. The interim commission, composed of the nominees of 18 States, was at work on the rapid and effective establishment of the Organization. The constitution had been signed by 61 nations, but needed the ratification of a minimum of 26 before it came into being. Under the constitution of the W.H.O. there would be no interference with the practice of medicine in any country. He realized the concern over possible regimentation of the profession; this was in the minds of those engaged in the work of framing the constitution, but there would be no attempt to control the practice of medicine in any way whatsoever. The Organization would help all bodies engaged in securing the better health of the people, and, well aware of its responsibility, it desired the advice of bodies which could speak for the medical profession.

Nomenclature and Constitution

The Conference agreed that the name of the new body should be "World Medical Association." The French, Greek, and Spanish delegates desired to retain the name A.P.I.M., mainly for reasons of sentiment. Mr. SCOTT STEVENSON, one of the observers on behalf of the American Medical Association, said that a good precedent had been afforded by the change from "League of Nations" to "United Nations." One delegate proposed "World Federation of Medical Associations," but it was pointed out that "federation" involved legal complications.

An amendment to retain the name "A.P.I.M." was rejected by 14 votes to 22, and the name "World Medical Association" was agreed to on the motion of Dr. I. C. MICHAELSON (Palestine Jewish Association), seconded by Dr. J. A. PRIDHAM (B.M.A.).

Some discussion took place on proposed functions of the new Organization. Dr. ROUTLEY was anxious that one of its tasks should be to assist and foster medical education, both undergraduate and postgraduate, but the PRESIDENT pointed out that this was approaching the scientific side which had been accepted as somewhat outside the province of the new body. Dr. CHARLES HILL described what the B.M.A. had already done for the furtherance of international medicine, in particular the arrangement for lectures, by invitation, at Continental centres. Dr. O. C. CARTER mentioned the publication of the specialist quarterly journals and the introduction of the new medical abstracting service.

It was agreed that the members of the World Medical Association should be national medical bodies. The question was raised as to the existence in a given country of more than one medical association which might claim a national character. Dr. CIBRIE suggested that in that case the association which

¹ *British Medical Journal*, 1946, 2, 423.

was the more representative should be selected. The criterion of admission might be that the membership of the association included more than 50% of the practising doctors in the country. In France there was only one association. Dr. VIBAUT (Netherlands) pointed out the singular case of Palestine from which two associations were represented at that Conference—the Palestine Jewish and the Palestine Arab. Dr. ALFRED COX suggested that for the time being all who had been invited to attend the present Conference should be accepted as members, and that the membership question should be referred for permanent settlement to the committee which would be appointed. Dr. DECOURT mentioned Switzerland, where there were three national groups which had combined to send one delegate to the present Conference. Dr. LEUCH, the Swiss delegate, however, stated that there was only one medical association in Switzerland, the *Fédération des Médecins Suisses*.

A form of words suggested by Dr. C. HILL was agreed to:

The Medical Associations which are represented by delegates or observers at this Conference shall be eligible for membership, together with any other national or territorial medical association making application which is representative of the medical profession in its country or territory.

It was the desire of some delegates that the matter of the subscription be referred to the provisional committee, but on the motion of Dr. CIBRIE the Conference agreed, by 18 to 11, to fix the subscription. It was fixed accordingly at half the rate which obtained for the A.P.I.M., namely, at 10 centimes Swiss per member of each national group, up to a total of 10,000 members, and 5 centimes per member above the first 10,000, with a maximum of 1,500 francs Swiss whatever the number of members in a group.

A long and rather confused discussion then took place on the appointment of representatives to the Governing Body or Conference. Dr. CIBRIE urged that there should be only one member for each national organization, though the member might be assisted by an expert who should have no vote. He was anxious that all countries should have an equal voting power in the assemblies of the Association, the voting to be by countries, not by the number of delegates attending.

This matter was left for further exploration by the provisional committee, but it was the general feeling of the Conference that each member-association should have two seats on the governing body, and that whatever the number of delegates from national associations, the voting strength should be the same for each country.

Mr. M. LESSOF, who, with a colleague, was attending as an observer for the British Medical Students Association, asked that the committee to be appointed should be recommended to consider as eligible for membership of the Association the Medical Faculty Group of the International Union of Students. This was opposed by the Belgian delegate, Dr. SANDERVOST, who said that the Association was one of qualified doctors, and asked whether any national medical association admitted students to its membership. The French also opposed this recommendation. Dr. PRIDHAM for Great Britain supported it, as also did the Swedish delegate. Eventually it was agreed to recommend to the committee that the Students Medical Faculty Group be admitted as observers, with two representatives, but without a vote.

Secretariat and Committee

It was agreed that there should be two official languages in the Association—English and French—and that there should be a dual secretariat, in London and Paris. Dr. Charles Hill, secretary of the B.M.A., was appointed secretary in London, and Dr. CIBRIE, of the *Confédération des Syndicats Médicaux Française*, secretary in Paris, the appointments to be acting ones until the next Conference.

Dr. T. C. ROUTLEY proposed the appointment of a provisional Committee of nine persons, this committee to be charged with the responsibility of putting into the two languages a draft constitution and bylaws embodying the recommendations made by the present conference. He suggested that it should report back to the constituent associations and finally present its drafts to the first meeting of the World Medical Association, which would be asked to adopt the constitution as the instrument governing its activities.

Mr. H. S. SOUTTAR seconded, and said that behind the new Association would be the "armed force" of British medicine, and particularly of the B.M.A. Prof. J. F. BROCK (South Africa) urged that in forming the committee some regard should be paid to continents other than Europe. The A.P.I.M. suffered to some extent because it was thought of as only a European body.

The proposal having been adopted, a ballot was taken for the election of the committee, and the result was as follows:

Dr. F. DECOURT (France)
Dr. P. GLORIEUX (Belgium)
Dr. DAG KNUTSON (Sweden)
Dr. O. LEUCH (Switzerland)
Dr. J. A. PRIDHAM (Great Britain)
Dr. T. C. ROUTLEY (Canada)
Prof. I. SHAWKI BEY (Egypt)
Dr. L. TORNEL (Spain)
Dr. A. ZAHOR (Czechoslovakia)

It was agreed to recommend that the next Conference be held in Paris, the date and programme to be left to the committee.

Dr. O. RASMUSSEN (Denmark) referred to a report of a meeting of an international scientific commission held at the Pasteur Institute, Paris, on crimes committed by German doctors during the war; it was proposed to institute proceedings. He suggested that a report on the subject be presented to the next Conference. Dr. CIBRIE said that there existed in France an association of doctors of the Resistance movement, in which he had the honour to serve; it was now preparing a "blue book" on German atrocities. Dr. A. ZAHOR (Czechoslovakia) said that during the occupation 1,080 members of the Czech medical profession were lost—250 by execution, 520 as a result of torture, imprisonment, and general ill-treatment, 300 by exile, and 10 by bombardment. The memories of the dead could best be honoured by devoted work for international co-operation in the medical profession. Dr. I. C. MICHAELSON (Palestine Jewish) suggested that the committee should obtain information from its constituent bodies as to the number of refugee doctors still not absorbed and determine the general absorption rate sufficient to give employment to all refugees.

Dr. LEUCH (Switzerland) proposed and Prof. W. DENK (Austria) seconded a vote of thanks to the British Medical Association. Sir HUGH LETT said that it had been a great privilege to preside. If only they could secure international co-operation between the medical men of the different countries they would have gone far towards bringing about the permanent peace they all desired.

The Conference gave an ovation to Dr. Alfred Cox, a veteran of the A.P.I.M., who, notwithstanding his eighty years, had been as energetic as any in the work of the Conference.

B.M.A. DINNER TO THE DELEGATES

The President and Council of the British Medical Association entertained the delegates and observers to dinner at the Savoy Hotel on the first day of the Conference. Sir HUGH LETT presided, and the guests included the President of the Royal College of Physicians (Lord Moran), of the Royal College of Surgeons (Sir Alfred Webb-Johnson), of the Royal College of Obstetricians and Gynaecologists (Mr. Eardley Holland), and the Director of the British Postgraduate Medical Federation (Sir Francis Fraser).

The PRESIDENT, in proposing the health of the visitors, said that the urgent task was to prevent the continuance of so much avoidable suffering in many parts of the world. It was true that the conditions of a healthy and contented life lay largely outside the medical province, in the realms of political and economic affairs; nevertheless, the medical profession throughout the world could do much to alleviate suffering, and the co-operation of medical men of different nationalities would in itself help to promote understanding between nations. The new international association of doctors would also help to bring to fruition the work of the new World Health Organization.

Four replies were made to the toast. Dr. DECOURT recalled that it was in Dr. COX's office when he was secretary of the B.M.A. that the A.P.I.M. was founded. It soon comprised representatives of 31 nations. Some of its stalwarts were still present among them, but most of those attending the

present Conference were novitiates in medical internationalism. Dr. J. G. BERNER (Norway) prophesied a useful career for the new body in tackling the problems of medical practice in different countries. Dr. T. C. ROUTLEY said that the Canadian Medical Association which he represented numbered rather fewer than 10,000 members, but it recognized no boundaries where the brotherhood of man and the ministry of healing were concerned. The medical profession, in re-establishing world fellowship, could give a lead to other professions and vocations. Dr. J. J. BRUTEL said that among their own sufferings the Dutch people had watched and sympathized with their neighbours on the other side of the North Sea. British example had kept up their own spirits and stimulated their endeavours. He expressed gratitude to Britain for caring for Dutch refugees and also for what it had done since the end of the war to help Holland. He presented to the President a small commemorative plaque bearing the design of the Aesculapian serpent, with the house of the Netherlands Medical Association at Amsterdam as a background.

Prof. J. C. BROCK, in proposing the health of the British Medical Association, mentioned that he started his research career as a Walter Dixon research scholar. He spoke of the gracious spirit in which the B.M.A. had accepted the recent proposals from South Africa. The CHAIRMAN OF COUNCIL (Dr. H. G. DAIN) said that the Association, he hoped, would always be able to play its part on the international stage. They had been watching for some months the politicians trying to hammer out a formula of peace, with little success. He hoped that the medical professions of different countries might seize the opportunity to give a lead, and that other professions, too, would begin to think of world-wide contacts.

GOVERNMENT LUNCHEON TO "WORLD MEDICAL ASSOCIATION" DELEGATES

MR. ANEURIN BEVAN'S "INAUGURATION" SPEECH

The delegates and observers attending the International Medical Conference were the guests of H.M. Government at a luncheon at the Dorchester Hotel on September 26. The Rt. Hon. Aneurin Bevan, M.P., Minister of Health, presided, and was supported by several of the officers of the Ministry. The President, Chairman of Council, and other officers of the British Medical Association were also among the guests.

Mr. ANEURIN BEVAN congratulated the company on having brought to birth this interesting infant, the World Medical Association. He also testified his appreciation of the initiative and imagination shown by the British Medical Association in summoning the Conference.

"The British Medical Association has many virtues; I shall not this afternoon make any reference to its faults. When it leaves the field of inevitable controversy and is able to set aside any subversive predispositions, it takes an objective and scientific and philanthropic interest in the development of medicine all over the world."

The birth of new organizations was always important. On such occasions persons in his position were expected to produce abstract generalizations, often prosy and boring. He would resist that temptation, but he could not neglect taking advantage of the opportunity of pointing out that there was no more important contribution that citizens could make towards universal appeasement than to meet each other as fellow craftsmen and as members of the same profession. When politicians got together all kinds of friction were likely to arise, but when doctors assembled their concern primarily was not as to who was going to do a particular thing but that the thing should be done.

"It does not matter to the doctor whether his patient be black or white, brown or yellow, communist or fascist, rich or poor. There is in medicine a catholic interest in and dedication to the welfare of mankind, a concern for the individual quite independently of his social group or inheritance, his destination or his origin."

It was therefore of supreme importance, Mr. Bevan continued, that the organization which had been born that day should have a successful beginning and carry with it the enthusiasm of its founders. It was born with one great

advantage, which the British Medical Association would appreciate—it was not within official apron strings. It would be in an atmosphere of complete independence and freedom. Those who were in official positions stood in the background smiling benignly on its activities. It would proceed from infancy to adolescence and manhood without official interference.

At the same time, he hoped the World Medical Association would realize the desirability of working in closest association with the World Health Organization. Their functions would be complementary. That was a characteristically British way of development. It was usual in this country for the state to be made by the amateur. Experimentation in the way of voluntary activity came first and gave rise to a variety of ideas of unequal survival value which competed with one another. Then, when one emerged which commanded general acceptance, the State stepped in and gave it formal expression in legislation. It would be one of the functions of the new organization to try out various ideas and eventually present them to more formal organizations as representing the way in which, in the view of the medical profession, these things should be done. One of the functions of the new organization would be to seek to universalize for all mankind the particular services or arrangements which had proved beneficial in certain areas. He wished it every possible success.

Dr. J. A. PRIDHAM, one of the B.M.A. delegates, in responding, said that it was for each society or group to cultivate international co-operation in its own small field, and it was this that those who had assembled at that Conference were trying to do. For the medical profession this should be an easier task than for most, for sick and suffering humanity has a universal appeal, and "there are no visas or tariffs on the traffic of medical knowledge."

Governments the world over were taking a great interest in medicine—a welcome fact, although introducing a disturbing and unpredictable factor into their way of life. The tradition of medicine were centuries old; State medicine was of recent growth. A doctor practised the art as well as the science of medicine. If he was a pure scientist it would be so much easier to integrate him into the State machine. It was the combination of art and science that made medical practice fascinating—and so difficult. The raw material of medicine was human beings, not mere collections of bones, nerves, and blood vessels. A doctor, like a scientist, had to acquire a special mental discipline, but also a discipline of the heart. As the Minister had said, all suffering called for help, whether the sufferer were friend or foe, Christian, Mohammedan, or Jew. The doctor served them all. But when the organized State entered in to provide this service new difficulties arose. A new pattern had to be devised, but it must not be allowed to destroy the spirit of the old. They all realized that there must be some arrangement between the State and medicine, but they hoped it would be of the nature of a partnership or marriage, in which each served the good of the other and neither was subservient to the other. It was to be hoped that those whose particular sphere was politics would approach their common problem in the same way as the good scientist or the good doctor—that is to say, by humble, patient inquiry, observing, recording, deducing, and being ever ready when necessary to cast aside old theories and prejudices. Thus perhaps in medicine they might achieve the first really harmonious international society.

Dr. P. GLORIEUX (Belgium), in a further speech in response, after thanking the Minister, proceeded to make a declaration of the democratic faith of his Belgian medical colleagues. The profession in Belgium was firm in its resistance to political pressure. They believed with all their hearts that in a democracy the doctor must remain a free doctor and the patient a free patient.

Mr. H. E. Durham, Sc.D., F.R.C.S., of Cambridge, who died on Oct. 25, 1945, leaving £32,885 9s. 9d. gross, with net personalty £32,825 2s. 4d., bequeathed his real and leasehold property to his wife, and the residue to her for life and then to his children, who were failing: £2,800 stock to the Royal Medical Benevolent Fund, for the benefit of professional persons afflicted with total or partial loss of vision; his railway stocks and shares to King's College, Cambridge; £500 stock to the London School of Tropical Medicine; £600 stock to the Liverpool School of Tropical Medicine.

MANAGEMENT OF CEREBRAL PALSIES

Dr. EARL CARLSON, of New York, delivered a lecture at the London School of Hygiene and Tropical Medicine on Sept. 9 on "The Modern Management of Cerebral Palsies." The chair was taken by Dr. F. M. R. WALSH.

Infantile cerebral palsy, or spastic paralysis, said Dr. Carlson, was a disturbance of muscular movement which was as prevalent as poliomyelitis. It could be caused by anything that damaged brain tissue before, during, or after birth. The principal types of muscular dysfunction encountered were spasticity, athetosis, and ataxia, and these might be present singly or in combination. The degree of physical incapacity ranged from complete helplessness to a disturbance so slight as to be recognizable only when the patient was under emotional strain. Besides the obvious motor handicaps, speech disorders and difficulties in hearing and vision were frequent accompaniments and made the educational programme more difficult. Thus the spastic who was both deaf and crippled was not accepted in schools for the crippled because of the hearing defect nor in schools for the hard of hearing because of the crippling condition.

Degree of Mental Impairment

The mental state varied from idiocy to a superior intelligence, and the extent of mental disability bore no relationship to the amount of motor handicap. This was specially true in hemiplegic cases. Some children, in spite of having one good arm and leg and no speech involvement, had difficulty at school because of damage to the frontal lobe. They had an excellent memory for isolated facts but failed to organize the facts into a whole. It was not easy to determine the mental level of the cerebral palsied child. No test had been standardized on motor-handicapped children, but in testing children whose speech was intelligible the revised Stanford-Binet test had been found satisfactory. It was also necessary to make a careful analysis of special disabilities of speech, hearing, and vision. The majority of the cerebral palsied had speech defects, the extent of which bore no relation to mental impairment.

The outstanding characteristics of defective speech among spastics were (1) lack of smooth, rhythmic speech; (2) poorly articulated speech; (3) lack of nuances of inflexion, intonation, and volume. One child might need to learn to co-ordinate the expiratory muscle movements with the articulatory movements; another might make progress by imitating good speech models; another might require ear training or visual aid; another might require detailed explanation and demonstration; and yet another might require all these techniques and others in addition. Not infrequently the acquisition or improvement of speech came about with the successful accomplishment of co-ordinated muscular movement, without special emphasis on speech training itself.

Physiotherapy

Physiotherapy exercises must be adapted to the individual case. In spastic conditions the patient was taught to relax one set of muscles as the opposing muscle group was brought into action. Heat and gentle massage were sometimes helpful. Stimulating massage was contraindicated because it increased muscle tension.

In treating athetoid conditions relaxation was of primary importance. As the athetoid had better control of his muscular movements when fear, anxiety, and self-consciousness were in abeyance, training should keep him occupied and his mind diverted from his muscles, which could be done by directing his attention to the purpose of his act rather than to the muscles which performed it. Much reliance must be placed on vision in training. The child must look where he walked or focus on the object he was trying to reach. Occupational therapy was a valuable adjunct in treating cerebral palsy cases. Water treatment was often conducive to relaxation, but not as effective as in cases of poliomyelitis.

Surgery and Drug Therapy

Surgery was more effective in spastic than in athetoid conditions. Lengthening of the heel cord, stabilization operations on the ankle, tendon transplantation, and cutting the nerve supply

to the adductor and gastrocnemius muscles were helpful if followed by exercises. Little was accomplished for the athetoid by peripheral operations on nerves and muscles. The use of braces and splints was also more helpful in spastic conditions: except in mild cases, braces usually aggravated the athetoid condition. In some of the most distressing cases of athetosis cutting the extrapyramidal pathways in the spine had yielded favourable results.

Drug therapy in cerebral palsy had been unsuccessful. Sedatives should not be used except in convulsive disorders. Any drug which tended to depress the mental activity made the patient less responsive to treatment. Snake and bee venom and curare produced partial and temporary relief of muscular tension, but seemed to have no permanent effect and were highly toxic.

Education of the Cerebral Palsied

The traditional view was that the cerebral palsied could not develop mentally beyond the limits of his motor experience, since he had to translate his ideas into muscular activity to grasp them. Therefore the first object in treating the patient was to educate his muscles until some control had been obtained. The movements of a normal infant were inco-ordinated. At birth the brain was unable to select sensory impressions and translate them into purposive action. Until this selective capacity developed the baby grimaced and exhibited degrees of muscular rigidity suggestive of mild spastic and athetoid conditions. As the cortex developed and concentration on a purpose was achieved these aimless movements ceased. It was the same with the cerebral palsied child: fewer purposeless movements occurred when there was something to hold his attention. Education, therefore, was even more important for the cerebral palsied than for the normal child, and it was possible to develop the unaffected centres of the brain. The importance of concentration was evident in the ability of the spastic athetoid to use his hands better in the evening than in the morning: he had become interested in his surroundings.

The value of a school programme could not be over-emphasized. The effect of education on the emotions was important; it was through control of the emotions that the cerebral palsied learned to control muscular movements.

Vocational Problem

The sense of personal worth obtained by economic independence was the best medicine for the spastic, and much attention should be devoted to finding suitable vocations. As a small child, no matter how seriously afflicted, the intelligent spastic was happy; but as he grew older and more self-conscious he might become a social misfit unless he received careful guidance. The blind and the deaf were taught to circumvent their handicaps by braille and lip-reading, and there was hardly a vocation in which they could not excel. But with the spastic the determining factor was variable. With practice his co-ordination improved and he was able to do things previously impossible, so that he began to entertain ambitions, which again were thwarted by his handicap. A remarkable case was that of a man who at twenty years of age was selling newspapers on the street with a placard on his chest because his speech was so unintelligible that he could not call his papers. He determined to educate himself, and now held the M.A. and Ph.D., and was teaching academic subjects in a school for spastics.

Optimism in many cases of the cerebral palsied was justified, but they would never make a normal individual out of such, any more than out of the man with an amputated arm. His mentality might exceed the normal, but unless he had learned the limitations which his hyperactive nervous system imposed on him he was not going to be happy. The solution of the problem of the birth-injured, therefore, was far from being one solely of muscle training.

Dr. Walshe said that he felt a sense of reproach on reflecting how little had been done to help these sufferers, though it was true that certain operative procedures had been devised, including tenotomy, nerve section, and nerve crushing. Dr. Carlson's lecture was introductory to the work which Mr. Leslie Williams was now beginning at Croydon, where a school for spastic children was being founded—the St. Margaret's School for Cerebral Palsy.

Nova et Vetera

PRIMITIVE MEDICINE

Though till now there has been no lack of histories on the origins of special subjects (architecture, ceramics, etc.), there has not been any composed work on prehistoric medicine. Dr. Stéphen-Chauvet, who is the leading French authority on this subject, has set himself the task of elucidating it in all its aspects: morphological, physical, and ethnical.*

Documentary evidence of the palaeolithic and neolithic ages is almost non-existent. We have therefore to depend almost entirely on the evolution and civilization through which the earliest tribes are known to have passed. From statuettes, frescoes, and hewn stones certain deductions can be made. Internal pathology was much less important than external. In Oceania, for instance, we know that such diseases as syphilis, smallpox, tuberculosis, scarlet fever did not exist before the arrival of white people. A common feature of all the statuettes and frescoes representing prehistoric man is the difference between the sexes. Men, who hunted, fought, and worked, are depicted as of slender build; while women are all adipose, with big breasts, abdomens, and thighs, the result, no doubt, of their troglodyte and physically inactive existence reinforcing the hereditary enlargements of their endocrine glands.

Among prehistoric peoples it is evident that magic amulets and fetiches played a large part in the preventive or curative attempts to deal with maladies. The chapter on the methods used is well illustrated. In pharmacy the ancients employed purgatives, diuretics, vermifuges, and even antivenenes and aphrodisiacs. When dealing with external pathology, Dr. Stéphen-Chauvet has to rely mainly on the evidence of bone injuries, such as fractures, dislocations, and cranial wounds. He is astonished at the number of trephine cases that have been found to have healthy bone cicatrization and rarely with secondary osteitis. Dr. Prunières in 1884 found in 186 skulls which had been trepanned that some of the orifices were circular or conical, made by triangular pointed flints. It is, however, doubtful about the skull which is described on page 127 of this book as an Aurignacian skull from La Quina. Aurignacian (upper palaeolithic) skulls are of the neoanthropic or modern type. The skull on the cover, on the other hand, resembles the palaeo-anthropic type and is similar to some of the Neanderthal skulls. The supraorbital ridges are massive, though from the side view it is not certain that they meet in the centre to form a torus. There does not appear to be any canine fossa or mental eminence in this illustration. Dr. Chauvet leaves us in doubt whether the La Quina skulls were Aurignacian or Neanderthal in type.

This thoughtful and well-produced volume represents much antiquarian research.

HANN CHRISTIAN GOTTFRIED JÖRG [1779-1856] AND HIS "EXPERIMENTING SOCIETY"

In 1825 was published at Leipzig the first, and only, volume of Jörg's *Materialen zu einer künftigen Heilmittellehre durch Versuche der Arzneien an gesunden Menschen*, which may be freely rendered as "Towards a new pharmacology by means of trials of drugs on healthy men."

Explaining the purpose of the investigations described in his book, Jörg points out that many others have published reports of the effects of drugs upon themselves, but that such observations lose in significance because they bear the stamp of the individuality of the experimenter. He also insists on the fallacy of conclusions drawn from the pooling of individual published reports based on differing conditions of dosage and subject. It was Jörg's conviction that the way to rational therapeutics was by detailed collective observations of the effects of drugs on healthy persons, and that these could best be made by a group of auto-experimenters who would take the same drugs in progressively increasing doses, carefully noting both negative and positive results. "For my part," he says, "I shall not pause so long as my health permits, but shall continue and count myself fortunate if I can, every year or 2 years, produce a volume similar to the present one." For some reason Jörg's resolution was never implemented, although his literary output was considerable and included books on a wide range of medical subjects.

* *La Médecine chez les Peuples Primitifs*. By Dr. Stéphen-Chauvet. (Pp. 143; 101 figures. No price given.) Paris: Librairie Maloine, 27, rue de l'École-de-Médecine.

For the execution of his plan, Jörg formed a society—to which refers as the *experimentierende Gesellschaft*—of 21 volunteers, self making the 22nd. In addition, his 16- and 14-year-old Eduard and Theodor, were called upon as occasional guinea as also 3 discreetly anonymous females—45, 18, and 12 years of age. Most of the 21 members of the society were in their early two and a short description of each of them is given. Their constitutions are given as "robust," "healthy," or—more specifically—as "phatic," "arterial," or "arterial-florid." Temperaments are "guine," "choleric," "phlegmatic," "melancholic," or various combinations of these. The author describes himself as 45 years thick-set, and of average stature, robust constitution, and sanguine choleric temperament.

In his 500-page book separate chapters are devoted to report the experiments with each of 17 different drugs, which include hydrocyanic acid (in dilute solution), valerian, St. Ignatius's bean (which strychnine had been isolated 6 years before by Pelletier and Caventou), opium, digitalis, and tincture of iodine. It is interesting that valerian is described as "an unreliable drug . . . which remained without any discernible action, even in considerable dose or in some cases affected the head and in others the alimentary canal."

Jörg does not draw the obvious conclusions from his own observations, but prefers to regard valerian, on grounds that it is difficult to follow, as a stimulant, and to speculate on its mode of suppuration in the disorders for which it has been recommended by writers. This mingling of faithful observations with hypothesis which seem to be quite unwarranted by the evidence presented characteristic of the whole volume. Each chapter, devoted to a single drug, follows a similar pattern. About St. Ignatius's bean, for example, we are told that two preparations were used—a tincture and a powder. Then follow summaries of the reports of each of the experimenting members of the Society, with doses, date, time, and the sensations noted. Each experimenter starts with a small dose, notes his sensations, and then proceeds to higher doses. Engler, Friedrich, Glintz, Knesecke, Kummer, Lippert, Meier, Pienitz, Seyffert, Ströfer, Otto, and Jörg himself conscientiously noted headaches (particularly in the region of forehead and eyeballs), colicky abdominal pains, diarrhoea, and miscellaneous other symptoms. Summing up, Jörg concludes that the characteristic action of the drug is as a stimulant of the alimentary canal and brain. There is a conspicuous absence of any reference to strychnine—the actual principle—and the doses were evidently never so high as to cause convulsions.

From 52 pages of subjective reports of the effects of different doses of opium, Jörg concludes that it is "in no way so much to be recommended as the doctors have for centuries believed" and that "more various and stronger in its actions than the practitioners of the present time imagine." The light-headedness and feeling of incubation which followed the taking of opium are interpreted by Jörg as a stimulant action on the brain, and he notes that this was followed by drowsiness and later a deep sleep. He concludes that opium first stimulates, then depresses the whole organism, nervous system and the alimentary canal being particularly affected (as, indeed, would seem to be the case with most of the drugs tested!).

In spite of the poverty of real information on the action and effects of drugs that Jörg was able to gain, the conceptions underlying "experimenting society" were of outstanding merit when judged by the word-spinning and the uncritical empiricism of most of his contemporaries. Imperfectly as he was able to realize them, he seems to have clearly appreciated two important principles: that the effects of individual variation should be eliminated by comparable trials on relatively large numbers of test-subjects; and that comparable results could be attained only by use of drugs prepared by the same method and given in similar dosage. But perhaps of even more importance was his attempt to understand the actions and uses of drugs by study of their effects in the healthy organism.

There is a surprising lack of information on Jörg in the standard reference works of medical history. Garrison does not mention him. Nor do Sudhoff and Pagel, Castiglioni, or a number of shorter works consulted. In Puschmann's *Handbuch* (Neuburger and Pagel), there is a brief reference to him is confined to an appliance which he invented for the correction of deformities of the limbs. Hirsch's *Biographisches Lexicon* refers principally to Jörg as a writer on diseases of women and children (he was professor of obstetrics at Leipzig), although it is mentioned that he wrote also on materia medica and on toxicology. The only reference found to the *Materialen* is in Wailly's *Bibliotheca therapeutica* (1878), which contains a 14-line description of the work.

Perhaps the most striking impression made by this book on a modern reader is—pace the advocates of Clinical Science, and the medical historians who demand that we shall return to Hippocratic methods—of the extreme limitations of the method of unaided clinical observation, however carefully and honestly pursued. It is at about this time that Magendie in France was developing his pioneer work of animal experimentation with active principles of drugs.

Reports of Societies

RHEUMATIC DISEASES

At a scientific meeting of the Westminster and Holborn Division of the British Medical Association held on Sept. 12, with Dr. W. A. MILLIGAN in the chair, Dr. W. S. C. COPEMAN delivered an address on "The Rheumatic Diseases." He said that "rheumatism" was a vague term for a neglected and important subject, the aetiology of which was little known. Ministry of Health figures showed that twelve million of the population suffered from this condition. The Royal College of Physicians classification of 1936 was: A. Acute and sub-acute rheumatism, synonyms for rheumatic fever. B. The articular group—arthritis, the joints being involved: (a) rheumatoid arthritis; (b) osteo-arthritis. An exception was spondylitis of the spine, where both rheumatoid arthritis and osteo-arthritis were involved. C. Non-articular type, where soft tissues only were involved: 60% of the twelve millions. Removed from this group recently were those cases caused by prolapsed intervertebral disk.

Articular Group

Women were affected by rheumatoid arthritis five times as often as men. They were usually in the child-bearing age groups, and frequently bed-ridden—often within 18 months and for the rest of their lives. The patients were commonly of the asthenic type, as in tuberculosis. They were often pyrexial and thought to be infective. The condition usually started in the small bones of the hands and feet and travelled to the large joints and spine. Relapse was frequent, with early and complete crippling. A secondary anaemia, loss of weight, and glandular imbalance occurred, but threw no light on the aetiology. Some cases were infective (e.g., gonorrhoea). Osteo-arthritis was caused by "wear and tear" or trauma to one or more large joints—rare in upper extremity. The cartilage wore thin. The general health was good, and males were the most frequent sufferers. On x-ray examination the rheumatoid type showed atrophy and rarefaction (the American atrophic arthritis), whereas in osteo-arthritis there were osteophytes with overgrowth of bony and soft parts and widening of the joint (the American hypertrophic arthritis).

Non-articular Group

Fibrositis was once thought to be inflammatory and a disease of the muscles. It was now realized that any tissues might be affected. Biopsy showed three types at least: (1) fibrous nodules; (2) local areas of spasm; (3) small hernial protrusions of the fat through the muscle sheath. Features of the disease were definite painful points called trigger points, or palpable fibrositic nodules. General health, blood count, and blood-sedimentation rate remained normal. There was also non-localized fibrositis, as in influenza or sinusitis, due to an open focus of infection, in which the whole muscle was affected. Lastly there was a general condition in which the whole side of the body was involved; it might be psychosomatic or secondary to pain.

Methods of Treatment

Team work was needed, the minimum being the patient and the doctor; but the orthopaedic surgeon, the gynaecologist, the dentist, and the physiotherapist might be needed, the last especially. Physical methods should not be left to the masseuse. Rest should be ordered only in inflammatory cases; if misused it might cause adhesions. In the absence of active inflammation, movement was indicated, but the rheumatoid cases should be rested if possible. Plaster-of-Paris should be used to immobilize joints, and they should be put in extension. Serial plasters should be used, particularly for rheumatoid arthritis, because they prevented deformity. In later stages or less active disease the joints might need to be stretched or manipulated. Analgesics were valuable, especially aspirin. Cinchophen was useful for gouty cases. Iodine was justified in some cases, especially menopausal types. Sulphur and guaiacum were probably inert, but salts every morning seemed to be of some use, while cod-liver oil and arsenic were useful in the rheumatoid types. Gold was the best treatment for rheuma-

toid types, but dangerous in others; the dose was 0.5 g. in eight or nine weeks, and a water-soluble salt was best. Vaccines were not of proved value, and non-specific protein therapy was not as successful as gold, the effect not being lasting. Physical medicine was of great value, and in the U.S.A. psychological treatment now had a vogue. The patients should live in a warm or dry place. A high, sheltered situation, and the type of clothing were important. Industry was a potent cause not generally recognized, and some cases were directly occupational. Of patients in the arthritic group, if treated before two years had elapsed, 70% should be improved; therefore early treatment was indicated. The fibrositic group could be rendered free from symptoms in 80–90% of cases, but they were liable to relapse.

Answering questions, Dr. Copeman said that the condition got better in pregnancy, but rapidly worsened after childbirth. Aluminium, he thought, was not a cause. Rheumatoid arthritis did occur after the menopause, but rarely. Food was not a specific cause, but there was an allergic type. Fat cases should be slimmed, and thin cases fattened up; and he mentioned the use of insulin for the latter purpose. Vitamins were of no value, except perhaps vitamin B. Focal sepsis should be treated. He mentioned the use of local injections of anaesthetics, sterile water, or glucose in the trigger points of fibrositis.

RHEUMATIC CARDITIS IN CHILDREN

A meeting of the Medical Society of the L.C.C. Service was held at Queen Mary's Hospital, Carsbalton, on Wed., Sept. 4. There was an attendance of nearly 100 to see interesting cases of which the bone dyscrasias may have been unique.

Dr. THORNTON, of Queen Mary's Hospital, opened a discussion on the treatment of rheumatic carditis in children. All cases of true rheumatism suffered from carditis, which he divided into 3 groups: (a) fulminating, i.e., appearing initially; (b) acute, appearing in the first 2 or 3 weeks; and (c) smouldering. Complete recovery occurred not infrequently, but the incidence of permanent cardiac damage was high in instances where the rheumatic attack had been preceded by a definite attack of tonsillitis. Permanent valvular damage was present in 35.5% of a whole series of 1,100 unselected cases, but where the attack had been preceded by an acute tonsillitis the incidence reached 70%. The hearts of about 20% of children with rheumatic valvular disease were so severely damaged as to necessitate their leading restricted lives, and 3% were permanent cardiac cripples. In a third group of cases the damage seemed to be restricted to the conducting system resulting in persistent tachycardia or disordered cardiac action, and after generalized pericarditis had occurred expectation of life was inevitably short. Two unselected series of recently analysed cases of children admitted to hospital with rheumatism, 117 in each, showed that, in the children with tonsils present, 25% had severe cardiac damage, and 40% of the total had some cardiac damage. In the tonsillectomized series the respective figures were 12% and 28%. Children with rheumatic fever should not have their tonsils removed during the first three months of the disease, and not thereafter unless the erythrocyte sedimentation rate was consistently normal. Once a child developed permanent valvular damage it might in a large proportion of instances be said to be "written off."

Dr. GERALD SLOT entirely disagreed with Dr. Thornton's view that a child with permanent valvular disease was a complete "write off." He had followed several of these patients, who led perfectly normal useful lives, for over 20 years. Tonsils should not be automatically removed in rheumatic disease, as they were only part of the ring of lymphatic tissue round the pharynx, and removal of part of this ring would not necessarily be beneficial. Many physicians, especially in America and France, were conducting investigations on the lines that practically every child had had an early rheumatic infection, and that the specific changes seen in rheumatic fever were to be regarded as an allergic condition due to a previously infected heart. Dr. Slot fully agreed with Dr. Thornton on the need for rest, but pointed out the difficulty of deciding how long this rest should be. He suggested that when the pulse, the temperature, and the blood sedimentation rate had settled for a fortnight, the patient might be allowed up.

Correspondence

Postgraduate Education

SIR,—I submit that you have allowed the Colossus of London to dominate the picture of postgraduate education in the *Journal* of Sept. 14 to a quite disproportionate degree. In Scotland we are not unfamiliar with this provincialism of outlook, as it must, paradoxically, be called; but hitherto we have associated it with Whitehall rather than with Tavistock Square.

Two nosegays—I cannot call them bouquets—are thrown in passing to the great Scottish and other universities outside London, but otherwise your articles give credit to London and to London only. What is even more disconcerting is that your article entitled "Facilities for Postgraduate Education" devotes some 375 lines to London and only 25 to all the other universities and medical schools in the kingdom put together. Inasmuch as the title of the article purports that it is dealing with facts—and presumably facts in their proper perspective—this rather gross disproportion is open to criticism. Admittedly you say "all the universities are making postgraduate arrangements of some kind [the italics are mine] although, of course, on a very much smaller scale, except perhaps in Edinburgh." Even for Edinburgh it seems to me that this hardly redresses the balance.

Sir Francis Fraser, in another of the nosegays, refers to the pioneer work in postgraduate education which has been carried on in Edinburgh for the last forty years. This has now been intensified and extended under a joint Board representing the University, the Royal College of Physicians of Edinburgh, and the Royal College of Surgeons of Edinburgh—the three bodies which have formed the stable foundation of the Edinburgh Medical School for more than two centuries. Since demobilization began we have conducted no fewer than seven courses of the "fortnight's refresher" type for those in or going back to general practice. These have been attended by 230 graduates, and more courses of this sort will be held at regular intervals.

The Board has also instituted teaching on a level suited to those studying to become specialists, and preparing for higher examinations. In the past year two courses of ten weeks have been held in internal medicine and in surgery; 140 graduates attended the medical and 280 the surgical courses. In the coming academic year we shall provide two courses in surgery, each lasting five months. The course starting in October is already full with nearly 200 entrants; for the second course, due to begin in the middle of March, we have already 150 names. In medicine we propose to hold three courses of ten weeks each, beginning in October, January, and April; 150 names are on the roll for the first of these, opening on Oct. 7. Other projects that the Board has in view are courses in obstetrics and gynaecology on a specialist level, and the teaching of the basic sciences of anatomy, physiology, and pathology. —I am, etc.,

R. W. JOHNSTONE.
Chairman, Edinburgh Postgraduate Board
for Medicine.

SIR,—The issues raised by Sir Francis Fraser in the Frederick Lecture (Sept. 14) are vital ones. The concept of a Federation co-ordinating for teaching purposes all the talent of London's great hospitals will commend itself throughout the English-speaking world. Unless precautions are taken, however, there is a danger that if the recommendations of the Goodenough Report in respect of postgraduate teaching are implemented along the lines suggested by Sir Francis undesirable factors now present may be perpetuated and even increased.

Nearly 13 years ago, as a young graduate of under 4 years standing, I arrived a stranger in London after crossing 12,000 miles of ocean on a pilgrimage which many thousands of men and women from the younger countries have made before and since. It was to seek further postgraduate experience in Great Britain and preferably in London. Of the kindness shown and assistance given by so many senior colleagues, both at that time and in the years since, I can never speak too highly. My only fear in writing this letter is that my criticism of a method, or absence of method, of postgraduate education may be misinterpreted and attributed to a lack of personal gratitude. This

is not so. Fortunately there are many specialists in the United Kingdom who, if they happen to read this, will agree with the criticisms made, for these are the men who, realizing the great deficiencies which have existed in postgraduate facilities in London and elsewhere, have made every effort in their own hospitals and departments to provide appointments so attractive that the best men from over-seas, as well as from here will compete for them. In the same way the Fellowship of Postgraduate Medicine has done splendid work in organizing refresher courses in London. My comments deal only with postgraduate education for consultants and specialists, and chiefly with that aspect which affects visitors from abroad for it is on this that I am best qualified to speak.

In planning the Federation surely one of the first questions demanding an answer is what is meant by postgraduate education in medicine. The answer is not an easy one, for there are many aspects to be considered; and in the opinion of many, of whom I am one, it has been the failure to appreciate this which has been responsible for the unsatisfactory state of affairs now existing. If an effective system is to operate it must provide facilities for men and women with varying degrees of experience. It must provide for those who require refresher courses and for those who require prolonged clinical training in any of the special branches of medicine. It must demonstrate from the outset that the governing body of the Federation realizes that those facilities which are excellent for the one type of graduate are practically useless for the other. If these conditions are not fulfilled the system will be doomed to failure.

The man who comes to England after spending several years in resident and registrar appointments in large and efficient teaching hospitals in his own country comes usually with two main objectives. He wishes to secure appointments in which he can in the minimum of time secure the maximum of the experience he requires, and he usually wishes to obtain higher qualifications. Refresher courses can help him achieve the latter but they will do little to help him secure the former. He knows that the experience he needs cannot be given on mass-production lines, but must be achieved slowly and painfully as he works in personal contact with, and under the supervision of, those who having mastered are now prepared to teach. In terms of numbers the men who receive such training will be the few in comparison with the many who will attend the more popular and more academic refresher courses, but the prestige of the Federation abroad will be largely determined by the facilities it provides for the training of these few. They are the ones who once trained spread across the face of the earth and carry to forgotten places the ideals, traditions, and standards of work of the great hospitals which trained them. It has not been the thousands of occasional visitors attending refresher courses that have made hospitals such as the Brompton, Queen's Square, St. Mark's, the National Orthopaedic, and Chelsea Hospital for Women, to name but a few, such famous influences in world medicine. The secret of their success has surely been the soundness of the routine work done within their walls and the equally sound training given to those fortunate few selected for coveted resident posts. These men have acquired the professional skill, the human understanding, and the ideals of service to which Sir Francis Fraser referred, attributes be it noted which are not the prerogatives of the university teacher. Human nature being what it is the man who comes to London for postgraduate education does not come primarily to learn those important ideals, and I would wish to be the last to minimize their importance. In many, if not in most cases he has already been inspired at a more impressionable age by his undergraduate teachers. He visits London to learn more about the art and science of medicine and, if practice is made subservient to theory and the practical approach to human problems is given second place to the academic, then he will be disillusioned, and, a disappointed man, will seldom learn ideals from the one who has disappointed him. Hence lies the danger of entrusting the future of clinical postgraduate training to academic men occupying full-time chairs unless they have proved their practical ability and consultant status in competition with their colleagues. The contributions which they can make to the Federation are no less valuable than those of their less academic but more clinically minded colleagues. In fact, in some aspects of the work of the Federation their contributions will be by far the

The PORTANÆST

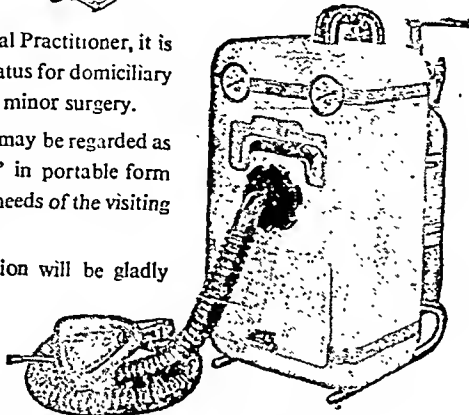

A Portable
Gas-Oxygen and
Gas-Air Apparatus

For the General Practitioner, it is
an ideal apparatus for domiciliary
midwifery and minor surgery.

In dentistry it may be regarded as
the "Walton" in portable form
and meets the needs of the visiting
practitioner.

Demonstration will be gladly
arranged.

One successful method of infant feeding alone can compete (in antiquity) with the Sphinx. Doubtless, when the latter at last succumbs to Time, breast feeding will still remain the unchallenged method of laying the foundation of health and vigour. For more than 40 years Cow & Gate Milk Food has provided a reliable and effective substitute when breast feeding proves impossible. It can therefore claim to have been "Tested by Time" even though this is measured in years rather than in centuries. During this period the application of increased knowledge of infant requirements and of process refinements has been continuous. The two standard foods in the Cow & Gate range are as follows:—

FULL CREAM

This food is found to be of suitable composition for the great majority of normal infants. It conforms approximately to the fat content of average breast milk. It is prepared from finest quality milk powder produced under carefully controlled conditions to ensure closest possible uniformity of quality. It contains 320 i.u. vitamin D per oz. and 1 m.g. of iron per oz.

HALF CREAM

When foods other than breast milk are first introduced, some children require a reduced fat intake. In a smaller number of cases it is advisable to continue with the lower fat content for several months. The half cream food, which contains the same vitamin and iron supplements as the full cream variety, has this reduction of fat and addition of carbohydrate in the form of milk sugar.

Particulars of these and other Cow & Gate preparations for specialised infant feeding, will be gladly forwarded on request.

THE VAGINAL TAMPON

—a significant contribution
to physiological and psychological
well-being

PRODUCED after the most careful study of the anatomy of the
vagina and the cervix in relation to normal menstruation,
Tampax tampons were designed to alleviate the mental strains and
physical stresses associated with the menstrual period.

The principle of the surgical tampon embodied in Tampax has
found solid support among women doctors, matrons and nurses.
Sense of security and comfort, the ability to live normally and
move freely during the period—these are the main benefits behind
this growing acceptance of Tampax, in which physical and psycho-
logical aspects are closely related.

Tampax may confidently be recommended by Physicians for use by married
women during normal menstruation. Its use by unmarried girls should not be
advocated when the size of the hyenal aperture would cause difficulty in insertion
and withdrawal.

greater, but the scope and influence of each should be recognized.

One disquieting fact which must be realized at this stage of planning for the future of postgraduate education in Britain is that the ties which have for so long united the younger countries of the Commonwealth to the Mother Country in matters medical have in recent years become weakened. There is a progressive tendency for the best men from the Dominions and Colonies to go elsewhere in search of experience. From South Africa and Canada more and more men are going to the welcome they receive in the United States, and this trend is now becoming manifest even in New Zealand, which up to the present has always looked upon it as a *sine qua non* that any doctor desiring to specialize would naturally go to Great Britain. In Australasia a further development has arisen with the rise of Melbourne as a great and keen medical centre offering excellent facilities for postgraduate study and experience. The result is that many men are asking why they should cross the world for training which they may or may not be able to obtain, when they have the assurance of securing it so much more easily and cheaply nearer home. Others, who are usually carefully selected graduates, when offered Fellowships as incentives to work in leading American clinics accept these gratefully but with a natural regret that similar facilities are not available in Britain. Now the disturbing fact remains that this tendency to disintegrate has developed in some places, and progressed in more, in spite of the work and influence of the British Postgraduate Hospital which was opened in London over 10 years ago. The scheme Sir Francis outlines of building a Federation around this hospital is not free from danger and may even lead to a further weakening of London's influence as a postgraduate medical centre. If those hospitals which have done so much on their own initiative, and without university support, for the advancement of medicine and the prestige of British practice are now to be grouped as scattered departments and institutes "of the Postgraduate Hospital then the union will not be an easy one. Questions of control, direction, and finance will become of paramount importance, especially when it is remembered that under a National Service the money for development will come from the University Grants Committee. The need for goodwill becomes obvious, but if this is to exist there must be adequate representation on the Governing Body of the Federation of those on whom the main responsibilities will fall for the conduct of clinical medicine in all its branches, remembering that these men will not usually be the full-time university professors.

One further way in which the Federation can be made the success which all would wish it to be is by co-ordinating its activities with those of the more important postgraduate units abroad, and particularly with those in the British Commonwealth. This means more than just welcoming visitors. There should be such reciprocity that selected men from abroad should work in responsible positions here and—of equal if not greater importance—selected men from here should work in corresponding positions over-seas. To make this possible in some centres the questions of reciprocity of registration will have to be settled. Only by this honest demonstration that we are as eager to learn as we are to teach will the full co-operation of the younger, and possibly more critical, countries be obtained at a time in our history when it is more necessary than ever before that the British Commonwealth should be united and sharing with sympathetic understanding a common destiny with all English-speaking people.—I am, etc.,

Oxford.

JOHN STALLWORTHY.

Selection of Medical Students

SIR,—Dr. D. H. Smyth's extensive review of medical-student selection (Sept. 14, p. 357) is both timely and stimulating. I was, however, glad to see the case for selection further expanded in your more informed leading article and some of his misconceptions corrected. It may interest him to know that when the original experiments in officer selection were begun in 1941 Army psychiatrists and psychologists took up the problem where he has now left it off. Some of the questions which were asked at that time were: What are the qualities required in an officer? How can these qualities be classified? What tests should be employed to elicit them? How should the

selectors be selected? What is the proper role of the expert? What administrative arrangements have to be made? How should selection integrate with training? Although most of these questions have been thrashed out and answered fairly satisfactorily nothing has as yet been published. This being so, and to minimize blind-alley thinking, it is as well to refer briefly to two major lessons learned in the Army after prolonged experiment.

First, it was found that the listing, classification, and testing of specific qualities was unproductive and unsound. It was soon realized that human personality is not made up of watertight compartments which could be tested independently; like peace, it is indivisible. The static, orthodox approach gave way to more dynamic concepts. To classify the officer's jobs and then to assess the candidate's effectiveness for these jobs was found to be easier and more sound. Since many men with different constellations of qualities could be equally effective in the same job it was of little value to match them against a standard pattern of qualities. Judgment had therefore to be passed upon officer effectiveness and not officer quality.

Secondly, the laboratory type of test, so dear to the heart of the traditional psychologist, was abandoned in favour of the group test. There was a shift in emphasis from the *in vitro* test to the *in vivo*. The laboratory test, in which conditions were artificially controlled, suffered the severe handicap that the individual was extracted unnaturally from his normal social context and subjected to a scrutiny that had little to do with real life. Bion's brilliantly conceived leaderless-group technique is a major advance in the study of personality. After over four years of trial this method has shown that in selection the assessment of interpersonal relationships is at least as important as that of technical competence. Poor "contact" in an officer proved as serious as poor ability.

Psychiatrists on teaching staffs of medical schools—many of them with experience of Army selection—are alive to the problem of medical-student selection. Your leading article points out "... a planned attack must be made on the problem," and again, "There is a research problem here of urgent importance." Not only has this been appreciated here in Aberdeen, but a plan for a three years' programme of research is already being worked out. An investigation will be made into the following problems: the best composition of the selecting team; the development of individual and group tests and interviews; job analysis; the comparison of students' progress (as judged by examination and reputational grading criteria) with predictions based on the experimental procedure. At the end of three years it is hoped that enough will be known to permit of specific recommendations for new procedures to be employed. It will require about six years before the experimental phase is complete and a routine procedure introduced. The fact that this project is being planned and run by the Department of Mental Health should allay Dr. Smyth's anxieties about "psychologists" who know nothing about medicine taking part in the selection of medical students.

The aim of selection is admirably summed up in the last sentence of your leading article. "... the more the selection findings can be used for guiding the student ... the easier will it be to achieve both good selection and good training ...". Teaching is not in fact simply the imparting of knowledge: it is a special type of human inter-relationship which has a therapeutic as well as an academic aspect. During his medical course the student, in addition to the factual knowledge he more easily acquires, must become a balanced, mature, humane, and wise person. He can only build up such attributes through personal contact with his teachers, and the ultimate success of teaching depends upon the cultivation of that relationship. A good teacher is not so much one who "knows his stuff" as one who knows his students. It would be the aim of selection to promote this latter knowledge.

But for the "planned attack" to be effective it is not enough that it should be carefully organized for any single research project by any one medical school. There is a need for some central body which can direct and co-ordinate research in a number of medical schools. A co-ordinating committee should be convened for this purpose. What is required is rationalized research, in which the reputation of any single medical school is made subservient to the common good.—I am, etc.,

University of Aberdeen.

D. R. MACCALMAN.

SIR,—Your leading article urging the co-operation of medical and non-medical psychologists in the selection of medical students (Sept. 14, p. 375) will be endorsed by all psychologists working in universities possessing both medical and psychological departments. But there is one remark which they are tempted to question: "the psychologist has advanced our knowledge of testing abilities, but the major developments in methods for investigating personality have come from medical psychologists." The view that psychologists have been chiefly concerned with the development of tests for intelligence and the like has been repeatedly affirmed by non-psychologists and as repeatedly denied by psychologists themselves. Can the writer cite any authority for his statement? Glance at the references given in standard works on personality by Allport or Cattell; less than 20% are by medical writers, and most of these deal mainly with theoretical inferences from the study of pathological cases. The most systematic researches of "methods of investigating personality" among students have been those concerned with the selection of members for the teaching profession; and these, almost without exception, have been carried out by psychologists. Even the methods of selection in the fighting Services, to which your article refers, have been mainly taken from the field of educational or industrial psychology. —I am, etc.,

University College, London.

CHARLOTTE BANKS.

SIR,—May I offer some comments on the articles you published on the subject of the selection of medical students (Sept. 14)? I am confident that psychological methods could be usefully applied to this type of selection, but there are some details in which my views differ from those expressed by your contributors and in your leader.

A misleading idea of the proper psychological approach to such a problem may be given by too liberal a use of such terms as conscientiousness, sympathy, tact, etc. In order to design an efficient procedure one needs to relate observations made at two points in time: the first, when selection can be applied to a candidate; the second, when his success as a doctor can be judged. The evidence is used to argue from observations made at the first point to observations expected at the second. Terms such as those mentioned, since they describe qualities not directly observed, can only be used as intermediate terms in this argument. Out of the many observations which can be made conveniently and precisely at the first point they may provide a preliminary indication of what is to use. But they may also mislead. Thus Dr. D. H. Smyth includes from arguments about the general nature of interests attempts to assess them are not likely to be reliable or profitable. He recommends assessing only intellect and character. But can we in fact form any opinion about a man's character without collecting any evidence about his interests? Does not this argument lead us to ignore observations which can be made relatively conveniently, precisely, and perhaps usefully, and send us in quest of intangibilities? The condition of the candidates' teeth was reported by Dr. Fraser Roberts at a recent meeting of the Royal Statistical Society as second only to intelligence-test results in usefulness for selecting naval cadets. Could this result have been anticipated by general arguments about the nature of mental traits?

Dr. Smyth's view that the quality that should be estimated is "the ability to do whatever work is undertaken after qualification" rather than success in the second or final M.B. examination is also one that may lead to an incorrect appreciation of the problem. There is, as your leader states, an exceptionally wide variety of jobs open to the doctor; and a qualified man has a very good chance, judging by the evidence, of finding some work which he can undertake with satisfaction and success. But this also makes it exceptionally difficult to relate observations made at the time of selection to such diverse evidence of success. On the other hand, if a man fails to qualify speculation on the success he might have achieved after qualification is idle. Moreover, the open examinations provide a yardstick by which students selected and trained in different ways can be fairly compared. Training for the medical profession constitutes a "successive" selection procedure, and in such procedures, as I have already shown (1946), the most economical method of selection is to choose at each stage the men who have the highest probability of

succeeding at the next. Finally, as every method of selection involves establishing an expectation from given observations a point in time must always be defined at which this expectation can be reviewed and judged correct or incorrect, other than there is no means of judging good selection from bad.

I have some doubts about the suggestion in your leader article that the War Office Selection Boards provide a suitable model for the selection of medical students. The analogy between the selection of officers primarily for infantry regiments and that of medical students is not close. The National Institute of Industrial Psychology has been consulted for twenty years by prospective medical students and has there had exceptionally useful experience in developing methods assessing their suitability. May not this experience prove more relevant? But if your analogy is admitted as valid, would not be advisable also to consider the appropriateness of methods employed in the selection of officers for the Royal Navy? The relative cost of alternative methods should also be taken into consideration. Of two equally successful methods the more economical should certainly be preferred.

But as you have raised this matter, might not this be a suitable occasion for inviting the War Office to publish a scientific scrutiny of the results obtained by W.O.S.B. methods? I would suggest particularly any evidence that is available to answer the following questions: (i) How much do they add to the selection procedures applied to candidates before they reach the Boards? (ii) How much of an improvement are they over methods previously in use? (iii) To what extent do they establish consistent standards at the different Boards? The final question is relevant to your point, "Common standards must be attempted, otherwise there will be injustice." —I am, etc.,

London, W.1.

True Mediterranean Fever in England

SIR,—In your issue of July 20 Dr. E. F. Hunt, of Chichester, Hants, gives an account of what he describes as "a true case of Malta fever infection by *Br. melitensis* in this country." If this claim were substantiated the position would be a very serious one as no case of indigenous infection with the *melitensis* variety of this organism is known to have occurred in this country. *Melitensis* infection usually causes more severe illness than *abortus* infection, and the infection in this case was alleged to have been acquired from the milk of goats, infection in which has been looked for by various investigators for at least eighteen years but has never been found.

It is therefore of the greatest importance that the truth in this case should be made known, so that Dr. Hunt's letter shall not stand unchallenged in the literature. Because of the importance of these issues very thorough investigation of the factors concerned was instituted, and the results so obtained have been uniformly negative.

Let me take first the alleged infection in the goats whose milk had been consumed by the patient. The pathologist on whom findings this statement was based found agglutinins for *melitensis* but not for *Br. abortus* in the blood of one goat. This in itself makes the diagnosis extremely doubtful and subsequent thorough investigations by the Ministry of Agriculture's Laboratory at Weybridge of the blood of all the goats in the flock and the milk whey of the three nanny-goats, as well as culture from the milk of these nanny-goats, have all proved entirely negative, as have also biological tests of the milk by injection into guinea-pigs. Similar agglutination, cultural, and inoculation tests on two male goats, three female goats, and two kids comprising a herd in which one of the male goats was used to serve the nanny-goat in the original herd which aborts have all proved entirely negative.

Now as regards the diagnosis of the patient's disease, Dr. Hunt states that the agglutination test was negative to *Br. abortus* but was positive to *Br. melitensis* in a dilution of 1 in 10. Such a titre has never been considered as diagnostic in itself, though of course it is well known that agglutination is sometimes negative throughout the course of this disease even when a positive blood culture is obtained. In this case, however, the culture of both the blood and urine was negative and the blood count gave 88% polymorphs and 6% lymphocytes, with a total white count of 4,700. This is not at all suggestive

lulant fever. The clinical picture, into which I need not enter in detail, was consistent with undulant fever but, unfortunately, so are the clinical pictures in many cases of many other diseases.

Whilst I cannot help deploring the haste with which a diagnosis was published in this case, this may, I hope, be partly compensated for by the warning which it gives of the care which should be exercised in coming to conclusions in this still elusive disease.—I am, etc.,

Ministry of Health.

WELDON DALRYMPLE-CHAMPNEYS.

Tobacco and Ulcer Dyspepsia

SIR,—While in no way disputing the findings and statistical validity of Messrs. Jamieson, Illingworth, and Scott (Aug. 31, 1946), there are two very important combinations of the factors which they have ignored: individual dosage and route of absorption. Dosage cannot be divided crudely into heavy, medium, and mild, depending upon the amount of tobacco usually consumed. The dosage of belladonna in my Parkinsonism patients varies from 18–360 minims (1.1–21 ml.) per 24 hours, and in each case the requisite dose gives the same amount of subtoxic result; therefore 18 minims is just as big a dose as 360. I have seen a goodly number of patients who get undoubted symptoms of tabagism before they have consumed one cigarette, so that one cigarette per day may be as bad as smoking for some persons.

Differences of toxicity depending upon the route of absorption are still ignored, though it is some years since I pointed out. Thus mercury through the skin is little toxic, by stomach it is very; lead does not give plumbism in enormous doses by skin or vein, but by stomach or lungs traces are deadly; ingested does much good by mouth or injection, but traces inhaled cause degeneration of the lenticular nucleus; fluorides consumed in large amounts in wines, etc., abroad with no results, but inhaled they cause deadly hurt. Tobacco smoked by mouth does very little harm, but inhaled is sympathetically hepatic-depressant. Cigarettes are always inhaled; light pipe mixtures are usually inhaled; and heavy smokers will inhale the strongest tobaccos.

The excited "jittery" person takes to cigarettes; he has not the patience for the longer pipe and he inhales deeply but not consciously; this depresses his sympathetic side with resultant gastroparesis, which induces traction on parts of the stomach and duodenum because these parts are relatively fixed by the gastric "ligaments." This leads to local ischaemia of the stomach wall—well-known parts of the pyloric antrum and the duodenum, for the blood vessels of these parts may not be as elastic as the mesentery, and anyhow the lengthened vessel is bound to be reduced in calibre proportionately to the new length. Thus tobacco inhaled may be seen to be important in the aetiology, but unless these data are recognized it will be found that tobacco may seem to have no place in causation. Cutting down cigarettes, which is often advised, does no good; the one who does it invariably inhales all the more to get the desired result, so that the man who reduces from 20 to 10 may get more poisoning from the 10 than from the larger number. Even if it takes about 6 weeks to get the effects of tobacco inhalation away from the sympathetic system of a severe addict, the relationship of tobacco inhalation, not smoking, to dyspepsia and ulcer formation requires a real investigation; it is not yet been done.—I am, etc.,

Bristol.

A. T. TODD.

SIR,—Dr. Anthony C. Hamer's attempt to classify smokers according to types (Sept. 14, p. 402)—the lean cigarette smoker and the placid, comfortable pipe-smoker—is interesting. But is it not time at someone protested against the silly theory that smoking is a "reversion to the infantile sucking instinct"? What justification is there for this theory other than that of a would-be-guess? If mankind has to sublimate his "sucking instinct" by smoking it should seem strange to the logically-minded that he never felt this urge until the 1600's, when tobacco was generally introduced. Strange, too, that men (and women) are prepared to pay the price of tobacco when a three-halfpenny teat would be cheaper and equally effective. And the pipe smoker is psychologically sucking his mother's teats, so surely we should regard the gum chewer as a cannibal who is actually masticating them.

A protest, too, must be made against these loose remarks about nicotine. It is "swallowed in mouthfuls," and produces "nicotine-stained hands," according to Dr. Hamer. But the fact is that nicotine is colourless, and the brown stains caused by smoking are due to the products of combustion and would equally result from smoking brown paper. By all means let us observe that cigarette smokers have stained fingers, but do not let us be so unscientific as to speak of "nicotine" stains. With regard to the "mouthfuls of nicotine" said to be swallowed, it might be well to remember that tobacco contains about 2–4% of nicotine and that much of this is said to be destroyed by combustion. What is swallowed is saliva mixed with pyridine bases, particulate matter, a *soupe* of the brothers Mono- and Di-oxide, and just a possible pinch of nicotine which had escaped combustion and condensation.—I am, etc.,

Alverstoke.

W. H. EDGAR.

Endotracheal Tubes

SIR,—The rubber endotracheal tubes that are available for purchase at the present time are so hard that bleeding from the turbinate bones is easily caused during intubation via the nose, and this might bring the endotracheal technique in anaesthesia into disrepute.

These tubes can, however, be effectively and permanently softened by immersing them in ordinary kerosene, or lamp-oil, for one and a half hours. The tubes swell up somewhat during this process so that a size three Magill nasal tube, for example, becomes as large as the number five. Different degrees of softness can of course be produced by varying the time of immersion in the oil.—I am, etc.,

London, W.1.

J. U. HUMAN.

Chronic Undermining Ulceration

SIR,—Owing to much travelling I have only just read Mr. Aubrey Leacock's article (Dec. 1, 1945, p. 765) on chronic undermining ulceration. In North India we saw many cases in infants of severe phagedenic ulceration of the scrotum, in some cases both testicles being denuded. All except those moribund on admission reacted very quickly to dressings of potassium permanganate and left us only with a problem of surgical reconstruction.

I assume that the action in these cases is due to the high oxygen content. I suggest that potassium permanganate is easier to come by than zinc peroxide, used by Mr. Leacock.—I am, etc.,

Liverpool.

GLADYS RUTHERFORD.

Penicillin Treatment of External Eye Infections

SIR,—I should like to add a few of our observations to Mr. J. Minton's article (Sept. 7, p. 324) on penicillin treatment of common external eye infections.

We find that although chemical lesions of the conjunctiva, especially lime burns, heal with less adhesions when treated with penicillin drops or ointment, complete healing of the lesions can be accelerated when the penicillin treatment is discontinued after about 1 week and replaced by sulphacetamide drops or ointment. Continued application of penicillin seems to delay the healing of these lesions.

Lacrimal sac infections which recur after treatment with penicillin drops and probing will often clear up with repeated syringing (twice daily) with penicillin 500–1,000 units per ml.

We also find that the skin lesions in herpes ophthalmicus will heal very quickly when treated with penicillin ointment, and if secondary infection is heavy with a course of systemic penicillin—15,000 units of penicillin intramuscularly every 3 hours up to 500,000 units. The post-herpetic pain seems less severe and if treated early enough the skin lesions seem less numerous and less extensive.—I am, etc.,

P. H. MERRORY,
Registrar.

Wolverhampton and Midland Counties
Eye Infirmary.

SIR,—Mr. Joseph Minton's paper on penicillin for external eye infections (Sept. 7, p. 324) prompts us to comment on some of the points that he raises. Mr. Minton states that he would expect his anhydrous ointments of penicillin in "eucerin L.M." to retain their full activity for over six weeks. We have found

that such ointments based on eucerin and containing 1,000 Oxford units per gramme show no noticeable signs of loss of activity after being kept at room temperature for over four months. By comparison it is of interest to note that an aqueous penicillin cream made with "eucerin L.M." and possessing an initial activity of 500 Oxford units per gramme will lose not more than 50% of its original activity after fourteen days' storage at room temperature; kept in the refrigerator such creams will retain at least 50-60% of their initial activity after three months. Similar results have been recorded for "eucerin L.M." creams by Greey and Hebb.¹

It may be helpful to your readers if we add a few words on the difference between the original eucerin base ("eucerin anhydrous") and "eucerin L.M." We were first prompted to investigate the suitability of a eucerin type of base for the preparation of penicillin creams by the fact that "lanette wax," the base originally advocated for penicillin creams by the Medical Research Council, was found by a number of workers to exhibit certain unsatisfactory features. Among these were liability to cause irritation, conflicting reports regarding the stability of penicillin in creams based on the M.R.C. formula, and variations in the pH of the base. It was soon found that eucerin was useful and in some cases preferable to "lanette wax." However, constructive criticisms, particularly from Dr. M. Sciler of the Luton and Dunstable General Hospital, led us to develop a modified base which we called "eucerin L.M." and which has since been found very suitable for the preparation of penicillin creams.^{2,3} This base, like eucerin itself, is of constant pH, conferring upon the aqueous phase a pH of about 6.5, and it was therefore expected to be particularly suitable for penicillin. The absence of irritant effects and the softness of the cream would appear to make it especially useful in eye work.

The main difference between ordinary "eucerin anhydrous" and the new base "eucerin L.M." is purely physical, the latter being more easily emulsified at ordinary temperatures and giving rise to a softer cream. There is no noticeable difference in the stability of penicillin in the two respective bases; both are anhydrous and neither gives rise to irritant effects. "Eucerin L.M." has therefore, in our opinion, no particular advantage over "eucerin anhydrous" in the preparation of anhydrous penicillin ointments for general work. It is, however, to be preferred for use in hydrous penicillin creams and, owing to its softer texture, particularly perhaps for eye work.

We agree with Mr. Minton's comments on the official B.P. ointment, and we feel with him that careful attention must be given to the points he raises if such an ointment is to be used with success. In particular, the possibility that he points out of pH changes in an ointment based on wool fat warrants careful examination. This danger of free acidity developing does, of course, not arise when eucerin bases are employed, as we are dealing with preparations of wool alcohols, which are free from the acid components still present in wool fat. —We are, etc.,

Herts Pharmaceuticals Ltd.,
Welwyn Garden City.

Erythroblastosis: Liver and Brain Lesions

SIR,—On June 29 you published an article by R. J. Drummond and A. G. Watkins¹—in which they show that chronic hepatic enlargement in children and adolescents may have its origin in congenital haemolytic disease. They suggest that Rh-factor investigations might reveal the cause in some cases of familial hepatic cirrhosis. On the other hand, it is well known that the icteric form of erythroblastosis often leads to damage of the basal ganglia and of other nuclear masses (kernicterus) and that a number of survivors suffer from a permanent affection of the nervous system. I have seen a case of double athetosis in which the family history was extremely suggestive of Rh-dyscrasia.

If then erythroblastosis can produce chronic liver damage on the one hand and chronic nervous disease on the other (especially disease of the lenticular nucleus) may it not also be an aetiological factor in those diseases in which the two pathological changes are found combined—Wilson's disease and

Westphal's disease? Some of the family histories in classical accounts of hepato-lenticular degeneration are well in keeping with this idea.

Kinnier Wilson's first case² was the youngest but one of children of whom 3, including the last one, had died in infancy. The two firstborn children were healthy as were some of the intervening ones. His fourth case was the last of three children of whom the first died at the age of 10 of ? tuberculous peritonitis, while the second was all right at the age of 22. At the birth of No. 3 (the patient) the mother had a miscarriage. Hadfield's case³ was the survivor of two children. The other one had died at the age of six with an enlarged liver and ascites and was certified as *tuberculous peritonitis*. Barnes's family⁴ consisted of 8 children. The three eldest were healthy, the following three developed progressive lenticular degeneration, the next had cirrhosis without evidence of lenticular involvement, and the last had a palpable liver at the age of the patient.

Not all the family histories on record fit in equally well with our hypothesis, but we know by now that the march of erythroblastosis does not always follow the classical pattern. The difficulties of fitting all the known facts into this Rh-theory are, however, enormous and I offer them together with a hypothesis to anyone who is interested. The facts seem to be suggestive enough to warrant further investigation, especially as the proof one way or the other should be a comparatively simple matter—viz., by Rh-investigations in sufferers from Wilson's and Westphal's disease and in their families. I am, etc.,

Surgeons Hall, Edinburgh.

Trilene in Midwifery

SIR,—Recent correspondence in your columns on the use of trilene in domiciliary midwifery reminds me that you were good enough to publish a letter from me on the subject (18, 1943). At that time I had been using Marrett's machine for over a year. I have now used it for more than four years in nearly two hundred maternity cases in private houses, in nursing homes, and I like it more than ever. With experience, this machine can give analgesia, amnesia, or full anaesthesia. I never now find it necessary to change to ether or chloroform. As overdosage is so quickly signalled by tachypnoea, and as dosage can be immediately adjusted by the six quadrant lever of this machine, there is never any anxiety. In a number of cases I have had the opportunity of comparing this machine with a standard gas and air machine, and in every case the patient has been strongly in favour of the trilene. Such remarks as "I wasn't getting much relief from that thing; but it made all the difference when I got your machine" are usual.—I am, etc.,

Ashted, Surrey.

W. EDWARDS

Africans, Peptic Ulcers, and Parasyphilis

SIR,—It is perhaps fortunate that Dr. Wright's Abolition of Africans (Aug. 31, p. 311), or for that matter the great mass of Africans, cannot read the large conglomeration of medical inaccuracies which has already been written about them. Dr. Wright should not be dismayed because history is repeating itself and we are again witnessing the outpouring of so-called authoritative pronouncements from medical men who have spent a few brief months only in tropical Africa. It does not appear that they have taken the elementary precaution to consult the easily accessible medical literature on their particular subjects before rushing into print with them. On the other hand we must not assume that peptic ulceration exists to a great extent among East African natives merely because Abdulla, a Nubian, who has lived on a diet of rice, eggs, maize, ehicken, and curries for most of his Kenya existence, has fallen a victim to this disease.

Abdulla's dietetic habits cannot be compared with those of the rural Nilotic Luo or the rural Bantu Kikuyu, and it is surely from these tribes, which comprise the great majority of the African population of Kenya, that reliable statistics must emanate—and these statistics will not be available until national hospitals in reserves are equipped with x-ray plants. As the

spitals have not yet emerged from the bucket-latrines and kerosene-lamp stage of development we shall, alas, have to wait many years for reliable figures. In the present state of our knowledge Sir Heneage Ogilvie and Dr. Wright are merely guessing, and their observations should not therefore be taken too seriously.

As regards parasyphilis, Dr. Wright is on much safer ground. Neurosyphilis is far from being unknown among East African natives. During a medical survey of a native population heavily infected with syphilis I found four undisputed cases among over 90,000 people examined. Reference to Dr. Gordon's work at Mathari Mental Hospital, Nairobi, would have been sufficient to dispel the illusion of the non-existence of parasyphilis among East African natives.

After twenty years' experience of East African tribes I would confirm the present position with regard to peptic ulceration and parasyphilis as follows: (1) Peptic ulceration is uncommon among rural East African natives but more common among their urban detribalized brethren. (2) The incidence of parasyphilis in relation to other forms of syphilis is low.—I am, etc..

"AJUGA."

Health Service Bill

SIR,—I fail to see the use of a referendum until the proposition is told the detailed terms of the Service on which it is to be voted. Few doctors will be voting for or against an ideology, but rather from the practical standpoint of the advantages offered by a State Service against those offered by the present methods of private practice.

Speaking as a general practitioner, there are certain advantages which a State Service could offer for which I would willingly give up my so-called freedom. I would wish to know first, that I am to be paid a salary which I consider an adequate recompense for the amount of work I do; for my professional knowledge; for the responsibility I bear; and for the position I have to keep up. I, personally, believe that all private practice should be abolished, and that all doctors should be paid salary and not remunerated by capitation fee. Only so can professional competition be eliminated, which, *per se*, leads to exploitation of the "bedside manner." Secondly, that I shall be paid a living pension at a reasonable retiring age. With present taxation and the high cost of living there are few who can even contemplate retirement before we drop in our tracks. Thirdly, that provision will be made for a twelve-hour day, which is certainly practicable in urban areas. What other "working man" is expected to be on duty day and night, 24 hours a day, 7 days a week, and for at least 11 months of each year? I fail to see where our freedom lies. The public, because of a free service (the N.H.I.) and the increased consciousness of health, expects so much of a doctor now that someone, for humanity's sake, must protect us against the greater labour demanded of us. We should be entitled to the same freedom as other men to give to our other pursuits and to our families, and the profession should have been sensible enough long ago to have instituted such a service within itself.

Nor do I see the practical purpose of a referendum (in the event of the majority of the profession voting against a National Health Service) unless the B.M.A. is ready to play its one and only trump card against a dictated Service, and, like all good trade unions, calls a general strike. If the Minister is not willing to negotiate, what other redress has the profession got? Are we to surmise that the B.M.A. is willing to do this?—I am, etc..

Englefield Green, Surrey.

W. E. R. BRANCH.

SIR,—In 1942, while D.A.D.M.S. of a division in the Middle East, I had to arrange discussions by British medical officers of the then proposed national health scheme. These doctors, whose ages ranged from 25 to 45, comprised a representative cross-section of the profession. They were all keenly interested and nearly all favourably inclined towards the plan. Two recommendations were made by that group: (1) That the serving doctors be kept informed of all progress; (2) That the final draft should wait until general demobilization to allow of consultation with the rank and file of the profession before reference to Parliament.

Since demobilization in April this year I have been able to discuss the new Bill with a large number of doctors, many

of whom are ex-Servicemen, in urban and rural practices in different parts of the country. Their unanimous antagonism towards the Bill struck me forcibly. I am convinced that this impressive change of attitude is due entirely to the despotic manner in which the Bill is being imposed upon us. Among the very men who were once so anxious to co-operate in the planning and working of a national health service there is now a bitter resentment and anger against the unscrupulous employment of political advantage to drag down the entire profession into the sullen, reluctant acceptance of a scheme in which the basic conceptions of British justice and individual liberty are so ruthlessly denied—denied, moreover, to a body of men and women whose pride has always been their personal and corporate service, their self-sacrifice and devotion to the needs of all people in both peace and war.

Drs. Zoë and Paul Harris (Sept. 21, p. 439) have clarified the issues and exposed the basic reasons for this bitterness and reaction. Others have pointed the way to a just remedy. Each and every one of us who believes that this Bill is unjust, contrary to our conceptions of individual liberty, and not in the best interests of the people and the profession must resolutely refuse to compound with those who seek its imposition; until reason replaces repression. We must realize that every advantage will be taken of us: our lack of unity, divergent interests, our innate dislike of "trouble," our fear that, unless we come in, we alone, or almost alone, will remain outside, and above all our absorption in the unceasing duty of caring for our patients, in whatever capacity we treat them. Who hate evil must resist it. Shall it be said of us that we, who counsel and tend others in their adversity, are helpless in our own cause?—I am, etc.,

Birmingham.

DOUGLAS VANN.

SIR,—I would like to reply to Dr. Norman Maple's comments (Sept. 14, p. 400) on my letter of Aug. 31. To confuse Nazism with Socialism is to reveal an extraordinary lack of political insight. This is regrettable, for without such insight it is impossible to understand the economic and social changes, including the integration of medicine, which must take place, and which are taking place in the world to-day. Dr. Maple obviously deplores the fact that a Labour Government was returned to power by less than one half of the electors in the country (and I presume that he would have been quite content if the party for which he cast his vote had been similarly returned), but we must face reality and accept the fact that the present Government was returned and is in power right now. What he and many others are in effect saying is that "democracy is all very well just so long as it doesn't touch us." It is naïve to a degree to suggest that the Minister of Health will have dictatorial powers. Every Minister of the Crown is responsible to Parliament. I quite fail to see how there can be dictatorship provided that doctors and other health workers make use of the democratic machinery which will be at their disposal. The profession will have adequate representation at all levels.

I am not uncritical of the Bill. I think it could be improved in many respects. Least of all do I suggest that Dr. Maple should be prohibited from making his attitude known in whatever way he thinks fit, and nobody can stop him from striking if he thinks it will do him or anybody else any good. I do maintain, however, that once the Bill becomes law we should do our best to make the Service a success and that we should thereafter constantly try to improve it in the light of experience. Finally, I repeat that I think an appreciable number of doctors will work in the new Service to the best of their ability despite the irresponsible accusations that they are "quittings," "traitors," "blacklegs," or what you will.—I am, etc.,

Scarborough.

PETER WADDINGTON.

Equal Opportunity for Specialists

SIR,—Medicine is gravitating towards State control and Mr. Bevan announces that it is hoped to operate the scheme contained in the Health Service Bill some time in 1948. When the Bill has become law the vast majority of the medical profession will in fact be servants of the State, owing allegiance to a common higher ultimate authority—the Minister of Health. The members of the profession will (so Mr. Bevan hopes) be united by a mutual bond, that of unstinted service for the

common health, and conditions of service within the State medical scheme will follow a uniform pattern according to grades—e.g., clinician or administrator, general practitioner or specialist. In the case of the specialist, and, in particular, that of the surgical specialist, I would make a plea for non-preferential consideration and equality of opportunity with regard to appointments. Is it just to preclude a surgical specialist with a diploma of Fellowship other than that of the Royal College of Surgeons of England from applying for specialist appointments as is very frequently the case at present? Will this selectivity persist when the profession comes under the aegis of the State, and does this suggest that political support may even be accorded to particular medical schools to the exclusion of others? It is devoutly to be hoped that no such bias will develop, for herein lies the threat of aggravation of the preference already in existence.

It is as true to-day as it was a hundred years ago when Dr. Andrew Combe in his "Memoirs"—quoted by Dr. John Brown in *Horae Subsecivae*—said: "The one great object ought to be the due qualification of the practitioner, and whatever will contribute to that end ought to be retained, whether it may happen to agree with or differ from the curricula of other universities or licensing bodies. The sooner one uniform system of education and equality of privileges prevails throughout the kingdom, the better for all parties."—I am, etc.,

W. R. BLACK.

Capitation Fee

SIR,—This fight has got to come, and the sooner the better. My own feeling is that the Resolution of the Insurance Acts Committee is not strong enough. We must be as uncompromising with the Minister as he has been with us, and as he obviously intends to be in the future. Though the Resolution notes the failure of the Minister to keep a specific pledge to apply the Spens Report to the current panel remuneration, it somewhat naively suggests asking him to renew and keep the identical pledge, or alternatively to pledge himself in advance to accept an interpretation by the Spens Committee or some other agreed-on body. We have learnt the value of ministerial pledges. More important still, perhaps, is the fact that reference to the Spens Committee or other body involves delay—possibly, on the Minister's part, intentional delay. As he is admittedly attempting to make the N.H.I. capitation fee the criterion of payment under the medical Service, it is essential, in our present interests and the future interests of the profession as a whole, that our attitude on terms of service should be definitely crystallized, if possible before the Bill gets its third reading in November and certainly before the Regulations are even discussed by the appropriate Parliamentary committee.

As I see it, we have now reached the last ditch but one in which to fight for proper terms. The suggested course of resigning from the N.H.I. is a pistol at the Minister's head which will be only at half-cock if we palter about asking for further pledges, the value of which we have learnt to assess to a nicety. This question of panel remuneration is one which affects our own present financial position no less than our future prospects. Definite and decided action now will have a very healthy moral effect. Fight, and no quarter!—I am, etc.,

Arlesey.

M. LETHBRIDGE FARMER.

The World Health Organization

SIR,—In the *Journal* of Sept. 21 (page 428) information is given about the World Health Organization of the United Nations. The functions proposed for this body appear to be useful, reasonably precise, and what might be looked for in an effort to share medical knowledge throughout the world. Unfortunately, some "principles" are announced as a basis of the work and these are either useless platitudes or clownish nonsense. What faith can be put in the work of people who announce that they will be guided by the proposition that "health is a state of complete (sic) physical, mental, and social well-being and not merely the absence of disease or infirmity"? Are the members of this organization to be people who believe that such a state is compatible with human life in a state of consciousness? If a poet spends nights in mental struggle and his son suffers from eating too many apples and his daughter is ostracized by the church choir, what is the World Health Organization going to do? Next it is declared that

"the enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being." Who conferred this right and who has deprived us of it? Then we are told that "the health of all peoples is fundamental to the attainment of peace and security and is dependent upon the fullest co-operation of individuals and States." If so, peace and security must be things as yet quite unknown and perhaps non-existent. Other "principles," equally ridiculous, follow, and lastly this: "Governments have a responsibility for the health of their peoples." God save the peoples!—I am, etc.,

London, W.1.

J. M. ALSTON.

Sir Almroth Wright and Anti-typhoid Inoculation

SIR,—I have read with interest the letter of Dr. Leonard Colebrook on the above subject (Sept. 14, p. 398). I was surprised to see that in Dr. Guthrie's *History of Medicine* the discovery of anti-typhoid vaccine was attributed to the late Sir William Leishman.

I would like to confirm Dr. Colebrook's letter from my own personal experience. I entered the Royal Victoria Hospital, Netley, as a surgeon-on-probation, A.M.S. (as it then was), in October, 1897, for a four-months' course of instruction. At that time Wright was professor of bacteriology there. During the course he was stressing the importance of anti-typhoid inoculation and did many inoculations among our members. His laboratory assistant was Capt. F. Smith, A.M.S. Sir William, then Capt., Leishman had only recently joined the staff of the Royal Victoria Hospital, and had no connexion with the bacteriological laboratory at that time.

I would further add that had he been alive Leishman would have been the first to disclaim any credit for this discovery, as he was one of the most modest and unassuming officers I have ever had the privilege of being associated with.—I am, etc.,

A. H. O. YOUNG,
Lieut.-Col., R.A.M.C.(Ret.)

Tavistock.

The False Preconceived Notion

SIR,—In an address to the Indian Congress of Philosophy last year I drew attention to a test for what Hippocrates termed the false preconceived notion but which, when you believe in it, you consider to be a well-established principle. The test is based on the capacity of the false preconceived notion to give rise to conflicting hypotheses of seemingly equal validity. If then one meets such conflicting hypotheses one should not humanly attempt to make choice between them but instead be critical enough to find out what all are agreed on and reject that. The simplest case comprises the conflicting hypotheses of dissociation and repression. Since both parties through these hypotheses agree that consciousness is a force, one rejects the assumption that consciousness is a force.

As noted by Parsons, the physiology of vision comprises a mass of hypotheses which are in conflict but of seemingly equal validity. Hypothesis-making may well be held to have run riot over dark accommodation. In this case the common factor is a belief that the natural stimulation of the eye is the same as the electrical excitation of muscle and nerve. We therefore drop this belief and get a clean slate to write on. I believe, however, that statistical treatment of those theories would "prove" that their common false assumption was true. I have taught my own students that the false principle, if firmly held, makes us puck-struck and starts us arguing to no result. Perhaps we are all puck-struck over shock. If such be the case, then after the next symposium of surgeons on shock some young surgeon should critically examine its proceedings to find out what theory about it his seniors agree on. This theory he should reject. After the rejection he will have an entirely new field to survey. He might even find that the word shock itself serves as a wand to Puck.—I am, etc.,

University of Rangoon.

W. BURRIDGE.

Pronunciation of Medical Words

SIR,—I would like a ruling on the pronunciation of the word schizophrenia. Even among alienists one hears a bewildering assortment of pronunciations: skizo, skitzo, skidzo, shizo, etc. I incline towards skitzo, but would like to know which is correct.—I am, etc.,

Bournemouth.

MARGARET VIVIAN

Obituary

T. WATTS EDEN, M.D.,
F.R.C.P.Lond., F.R.C.S.Ed.

Although Dr. Watts Eden had been living in retirement in South Devon for some years, he is still remembered as one of the foremost obstetric physicians and gynaecologists in London hospital and consulting practice for thirty years or more, and to many who knew him, both in professional and private life, will learn of his death on Sept. 22 with more than ordinary sorrow.

Thomas Watts Eden was born on May 8, 1864, at Evesham in Worcestershire. He was educated privately and took his medical training at the University of Edinburgh, graduating in 1888 M.B., C.M. with first-class honours. He said in later life that when he was capped bachelor of medicine he believed himself to be equipped with a great body of exact knowledge which would carry him through everything, but that his post-graduate career had been a salutary succession of discoveries of his own lack of omniscience and also of the fact that teachers and even textbooks might occasionally be wrong. But he had ground for self-confidence, for he was an exceptionally brilliant student. He gained the Ettles Scholarship, awarded to the most distinguished Edinburgh medical graduate of his year, also the James Scott Scholarship, awarded for the greatest proficiency in midwifery and gynaecology. In 1889 he received the Leckie Mactier Fellowship of the University as he graduate best fitted to undertake research. If Edinburgh left any gaps in his equipment, these were made good by later studies in London, Berlin, and Leipzig, where he gained practice in operative midwifery. In 1891 he proceeded M.D., again with honours. The Fellowship of the Royal College of Physicians of London and of the Royal College of Surgeons of Edinburgh were added to his distinctions some years later.

From the beginning of his career he devoted himself to the practice of midwifery and gynaecology. Apparently his first published writing was "A Study of the Human Placenta" in 1896. He soon acquired a high reputation in his chosen field. In 1906, at the time he wrote his *Manual of Midwifery*, he was already assistant obstetric physician and lecturer on practical midwifery to Charing Cross Hospital, physician to out-patients at Queen Charlotte's, and physician to in-patients at the Chelsea Hospital for Women. He retained his connexion with these three hospitals throughout his career, and on his retirement on reaching the age limit became a member of the consulting staffs of all of them. It was at Charing Cross that he had the greatest opportunity of exercising his teaching gifts. He once declared that it was obstetric teachers rather than obstetric teaching that needed reconstruction. Teachers, he said, should be men with a fair amount of leisure, and teaching ought to be their principal occupation instead of being, as it was with so many of them, a mere incident in a busy life. His life was busy enough, but he was nevertheless a popular and brilliant teacher, and generations of students learned from him lessons of incalculable value in obstetrics—resource in emergency, foresight, scrupulous care. He was first of all examiner in midwifery and diseases of women for the Conjoint Board, and afterwards examiner to the Universities of Oxford, Cambridge, Edinburgh, and Leeds. Thus he came to exercise a large influence upon the progress of midwifery in this country. He was one of those to whose work must be attributed the striking change in obstetrics and its practice, chiefly as a result of its permeation by the spirit of preventive medicine, which came about in the second and third decades of this century. He insisted that the conduct of labour must always be regarded as a surgical procedure; it was true that it might be, and generally was, the simplest kind of surgery, but, on the other hand, it might be transformed into a major surgical operation. Always an opponent of narrowness in specialism, or what he called "the keyhole view" of medicine, he insisted that it was the duty of the obstetric specialist to maintain his touch with normal labour by undertaking the private care of a number of such cases every year, in addition to his hospital work. The deplorable thing, in his opinion, was that complicated cases should pass into the hands of a few men

in each locality, while the remainder of practising doctors withdrew from midwifery work and left it to midwives.

With such ideals he helped to found the British (afterwards the Royal) College of Obstetricians and Gynaecologists in 1929. He was one of the first Fellows of the new College and a member of its first full council. He was also President of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, and in 1930 he succeeded Lord Dawson of Penn as President of the Society itself, being the second President since the amalgamation—Sir Francis Champneys was the first—to represent the province of obstetrics. On several occasions Watts Eden held office in the Section of Obstetrics and Gynaecology at Annual Meetings of the British Medical Association, and at Cardiff in 1928 he was President of the Section. From 1932 to 1940 he served the Association as a member of the Consultants Board, which was set up to deal with applications by practitioners for the inclusion of their names in the Consultants' List. Another of his interests was his membership of the Governing Body of the British Postgraduate Medical School. He was also an honorary member of the American Gynaecological Society.

Dr. Eden's best-known writing was his *Manual of Midwifery*, which went through seven editions. In 1911 he wrote a *Manual of Gynaecology*, and in 1916, with Mr. Cuthbert Lockyer, his colleague at Charing Cross Hospital, he produced a very large work, running to a thousand pages, entitled *Gynaecology for Students and Practitioners*, which went into four editions. In 1917, again with Mr. Lockyer, he edited *The New System of Gynaecology*. In addition he wrote numerous articles in Green's *Encyclopaedia of Medicine*, Quain's *Dictionary*, and the *Proceedings* of various societies. Early in his professional career he edited the *Journal of Obstetrics and Gynaecology of the British Empire*, and he continued to serve it as chairman of the Board. The *British Medical Journal* over a period of many years had the advantage of publishing reviews by Dr. Eden of works on his own subject. He was as conscientious a reviewer as he was a physician, and although some authors may have felt that he exposed their weak points, they could not complain that he had not read their books before reviewing them. A review, according to his practice, should include an outline of what the book is about, instead of, Macaulay-like, making the book a peg on which to hang a brilliant dissertation on its subject.

In the great inquest which occupied the attention of obstetrical circles during the years following the first European war, when the obstinately high maternal death rate seemed to defeat all efforts to bring it down, Dr. Eden took a conspicuous part. He served on the Committee on the Causation of Puerperal Morbidity and Mortality from 1925 to 1928, and in all the important discussions of that time his voice was heard, and always to some practical effect. It was his view that the general practitioner had not always been fairly treated in the criticisms which were forthcoming, and he insisted that in domiciliary midwifery which the practitioner attended the minimum of safety given by the presence of a trained midwifery nurse should be provided. The old-fashioned "handy-woman" he called an unclean anachronism, a reminder of the days which produced Sairey Gamp. No one was more earnest in pointing out the importance of antenatal and postnatal care.

Until well over seventy, when cardiac weakness prevented much physical exercise, Watts Eden enjoyed a round of golf, and in earlier days riding horseback. To one who had the privilege of his companionship the distinguishing features of the man were his modesty and lack of self-seeking, his moral courage and wisdom in counsel, his dry but kindly humour, and above all his tender concern for the welfare of friends.

NEIL MACLEOD, M.D., D.P.M.

His many friends and colleagues were shocked to learn that Dr. Neil Macleod, the well-known psychiatrist, had been found shot dead on the night of Sept. 21 in a ditch at Tingley crossroads, five miles from Leeds. A man was arrested later and charged with his murder.

For several years up to 1939 Neil Macleod was medical superintendent of The Retreat, the famous mental institution run by the Society of Friends in Haslington Road, York. He became honorary physician for mental and functional nervous diseases at York County Hospital and adviser in psychological

medicine to the regional headquarters of the Ministry of Labour and National Service in Leeds. He was born in 1894 in the Island of Skye and studied medicine at the University of Edinburgh, where he graduated M.B., Ch.B. in 1918 and M.D. with commendation in 1928. He joined the Army as a private in the 1914-18 war, but when the authorities found that he had medical knowledge he was transferred to the Navy and was present at the Battle of Jutland as a surgeon probationer. He took the English D.P.M. in 1924. Before taking up the post of medical superintendent of The Retreat he had been assistant physician at the Royal Edinburgh Hospital for Mental and Nervous Disorders, Morningside, and at the Sunderland Mental Hospital. He joined the B.M.A. in 1919, was a member of the Royal Medico-Psychological Society, and a past president of the York Medical Society. During his time in York and Leeds Dr. Macleod often gave expert evidence at murder and other trials. He contributed the section on psychological medicine to the eighth and ninth editions of *Savill's System of Clinical Medicine*. A brilliant after-dinner speaker, he was in much demand by St. Andrews societies and other Scottish gatherings in the North of England. He met and married his wife, formerly Dr. Mary Elizabeth Macarthur, while they were both on the staff of The Retreat, and he leaves her with two young sons.

Dr. PETER MACDONALD writes:

It was an overwhelming shock to see the announcement of the tragic death of Dr. Neil Macleod. His many friends, among whom I am proud to claim that I was one of the most intimate, will regard it as a disaster of the first magnitude. They will remember his genial character, his outstanding prowess as an orator, his apt phrasology, his quite remarkable choice of the fitting word, and with all and over all his transparent sincerity in everything he said and everything he did. He had not an enemy in the world, and those who knew him will treasure his memory with both affection and respect.

During his tenure of office as superintendent of The Retreat, it is not too much to say that he added lustre to that pioneer institution in the modern treatment of lunacy, and since he retired from that position he bade fair to become, in fact he had become, one of the leading psychiatrists in the North of England. His loss is a calamity not only to his many friends but also to the general public, who can ill spare him.

LIEUT.-COL. HASSAN SUHRAWARDY, M.D.,
LL.D., D.Sc., F.R.C.S.I.

Sir Hassan Suhrawardy (as he was known until recently) died in Calcutta on Sept. 18 aged 62. He was the first Indian to be appointed an honorary surgeon to the Viceroy of India, and had a most distinguished career in medicine and in the public service of his country.

He was educated in Calcutta at the Mohammedan Madras College and at the Medical College Hospital, where he held resident appointments. He subsequently studied in Great Britain, where he took surgical, obstetrical, and public health qualifications. On his return to Calcutta he had a distinguished professional career and rose to be Chief Medical and Health Officer of the Indian State Railways, honorary professor of public health and hygiene, and Vice-Chancellor of Calcutta University, vice-president of the Medical Council of India, and honorary consulting surgeon, Medical College Hospitals, Calcutta. He was the author of a *Manual of Post-operative Treatment* and of many papers. Great as were his professional attainments they were supplemented by public service and activities in many directions. He was a strong supporter of the Mohammedan cause in India and the Moslem League, and made a number of pilgrimages to holy places of Islam. As recently as 1945 he was appointed to the chair of Islamic history and culture in Calcutta University. He early entered the Bengal Legislative Council and became deputy president in 1923-5. His versatility is further shown by his appointments as President of the Board of Studies in Arabic and Persian and of the Calcutta Branch of the British Medical Association. He was also a first class magistrate and J.P., and did good work in organizing railway ambulance and nursing services. In 1930-3 he commanded the 2nd Battalion Calcutta University Training Corps.

In 1932 he was knighted immediately after a brave act in saving the life of the Governor of Bengal when a student attempted to shoot him in the Senate House of the University.

A very distinguished career was crowned by his appointment in 1939 as Adviser to the Secretary of State for India in London, a post he only relinquished in 1944. His whole life was one of devoted professional and public health service, which gained him universal respect and admiration. In spite of his political activities, he remained most loyal to his *alma mater*, the Calcutta Medical College, and did not fail when in Great Britain to visit his old medical college teachers. If Indians of his stamp and unswerving devotion to the interests of the Indian people as a whole are forthcoming in sufficient numbers to administer the country the outlook need not be despaired of. Sir Hassan renounced his knighthood a few weeks ago, when the Moslem League decided that all its members should give up their British decorations.

The untimely death, at the age of 59, of Dr. STEWART HODGSON, M.C., occurred at his residence in Edinburgh early in August. Educated at George Heriot's School, Edinburgh, he proceeded to the University, where he graduated M.B., Ch.B. in 1910. After a period as resident physician to the late Prof. Greenfield, in the wards of the Royal Infirmary, he began practice in the north side of Edinburgh and continued there to within a year of his death. On the outbreak of the 1914-18 war, Dr. Hodgson was gazetted to the R.A.M.C., and was awarded the Military Cross for his excellent work on the Western Front. After demobilization he resumed practice in Edinburgh, and was also actively engaged in Ministry of Pensions work, where his intimate knowledge of medicine proved of inestimable value in this department. At the outbreak of the recent war he quickly offered his services in A.R.P. duties, and was in charge of one of the aid posts which, owing to his enthusiasm and good example, was organized as a most efficient unit. Dr. Hodgson will be remembered with esteem by his patients and colleagues alike, not only for his efficiency, kindness, and sympathy, but also because of his cheerfulness and good humour. He joined the B.M.A. in 1920, and in 1935 represented his Division at the Annual Representative Meeting held in London. He was keenly interested in all forms of sport, and in his younger days captained George Heriot's Cricket XI. As a schoolboy he was outstanding in athletics, being games champion in two successive years.

Dr. JAMES WILLIAM ALBERT WILSON, of Wisbech, died while on holiday after only a few days' illness at the Royal Infirmary, Cardiff, on Sept. 10 at the age of 66. He was a native of Portaferry, Co. Down, and received his medical education at Queen's College, Belfast, graduating M.B., B.Ch., B.A.O. in 1903. He then went as an assistant to Dr. J. L. Thomas, who had a large colliery practice at Blaengarw, Glamorgan, and when Dr. Thomas left Dr. Wilson succeeded him. He soon won the confidence and even the affection of the Welsh colliers. One indication of his whole-hearted interest in the colliers' life and welfare was his study of miners' nystagmus. He made one of the earliest and most valuable contributions to the study of this industrial disease, and his thesis on this subject won him the M.D. degree in 1912. In 1915 he moved to Wisbech, but decided to join the Indian Medical Service for the period of the war, and was sent to German East Africa. Few doctors have had to solve such difficult medical problems as those that presented themselves to Dr. Wilson during the next two years. Although his health had been greatly impaired by malaria and dysentery during this period he returned to Wisbech in 1919 with his characteristic buoyancy and cheerfulness. In virtue of his medical and surgical skill, Dr. Wilson's practice soon became one of the largest in the Wisbech district. For many years he was honorary medical officer of the North Cambridgeshire Hospital, served on the Ely Panel and Medical Committee, and gained experience of public health work as medical officer for Walsoken, Walton, and Emneth. Dr. Wilson (writes E.O.L.) was a general practitioner of the best type—a keen and discriminating observer, well-informed in the most modern treatments, had a broad conception of the essentials of health, physical and mental, and, above all, a sympathetic understanding of human nature. At the present time, when many of us are concerned about the "municipalization" of the doctor, would that some of our best writers were to portray the drama, romance, and devotion of the general practitioner's life! Such writers could do much to stir the public and its legislators to a realization that our country will probably lose much more than it can possibly gain if the medical services are over-standardized. One danger of general practice is that it tends to exclude all other activities; the doctor has no time to be a citizen also. Dr. Wilson, like many others, avoided this danger and did so without neglecting his patients. He had made public interests. In 1923 (while chairman of the Ely Division

of the B.M.A.) he became a member of the Wisbech Borough Council and was mayor in 1932 when the late Duke of Kent visited the agricultural show at Wisbech. He took a lively part as a Liberal in politics, and his ready Irish wit made him a popular platform figure. In this field, as in all others, he was thoroughly sportsmanlike. The burial took place at Wisbech amid many manifestations that the town had lost a great citizen. A memorial service was held at the Congregational Church; every aspect of the town's activities and social services were represented in this large assembly. Dr. Wilson married twice. His first wife died in 1928. Heartfelt sympathy is felt with Mrs. Wilson, especially as it was but two months ago they settled in their new home and looked forward to years of ease and even greater happiness.

The death on Sept. 19 of JOHN HOWARD COOK, M.S., F.R.C.S., at his house in Hampstead, aged 75, removes the younger of a pair of medical brothers who were, in their own sphere, as famous as their contemporaries the Mayo brothers in the United States. They were the sons of W. H. Cook, M.D., of Hampstead, and both were educated at St. Paul's School, where each in turn swept the board in scholarships and prizes. Both in turn went to Uganda to the C.M.S. Hospital at Mengo, the reputation of which they placed on a firm foundation. The elder brother, Sir A. R. Cook, C.M.G., was there in time for the Uganda Mutiny of 1897-8, when he played a notable part in the medical care of the casualties: the younger brother joined him not long afterwards, and for many years they were undoubtedly the leading medical men in the infant colony, where sooner or later (and usually sooner) practically every white man passed through their hands as a patient. All the early writers—for instance, Sir Harry Johnston in his standard work on the Uganda Protectorate (1900) and Major H. H. Austin in his account of the Mutiny (1903), to quote only two—bore testimony to the selfless labours of these two medical missionaries, whose work contributed nobly to the prestige of European civilization in those troublous times. John Howard Cook, the younger brother, studied medicine at University College Hospital, whence he qualified as M.R.C.S., L.R.C.P. in 1895; in the same year he took a gold medal and scholarship at the London M.B., and in 1897 proceeded to the M.S. and the F.R.C.S.Eng. After working some years at Mengo he obtained the Diploma in Tropical Medicine of Cambridge University. Besides general surgery, he took an especial interest in ophthalmology, and he also played a prominent part in the investigation of and fight against African sleeping sickness. He was honorary consulting ophthalmic surgeon to the Church Missionary Society, having also been their physician and secretary to the medical committee. He was Harford lecturer in ophthalmology, and consultant for tropical diseases to the Ministry of Pensions. He left Uganda in 1920, and after 20 years more work for the C.M.S. in London he was then for 5 years medical superintendent of the London Medical Mission, Covent Garden. In 1899 he married Susannah Ethel Maddox. Their second son, Dr. Norman Cook, died in 1933 in West Africa, where he was a C.M.S. medical missionary, and the third son, Major A. Bickersteth Cook, M.B.E., M.B., B.S., is in the East. Mrs. Cook survives her husband; Sir Albert Cook has recently published a volume of *Uganda Memories*.

The death, on Sept. 18, of Dr. LEO POLLAK is a great loss, not only to White Lodge Hospital, Newmarket, but to the world of medicine. Before he came to this country, in consequence of the Nazi invasion of Austria, Dr. Pollak was Extraordinary Professor of Medicine in Vienna. About his work in this capacity he was very reticent, but among his personal friends he numbered some whose names are known to the world over, and it is probable that in more normal circumstances the name of Leo Pollak would have become equally well known. At the beginning of the war he was interned as an enemy alien, but was released from internment and became a member of the medical staff of White Lodge Hospital. There his circle of contacts was limited, but those who were privileged to know him recognized in him a great man. His professional knowledge was vast; he could give a learned answer to any question. Nevertheless, his erudition was associated with common sense and experience, so that his advice was very highly valued by all his colleagues. As a man, he was modest and extremely likeable. He earned the real affection of all with whom he came into contact, to such a degree that nobody can recall a single disparaging remark made about him. He had a lively sense of humour, which remained with him until his death, although he was fully aware of the hopelessness of his condition. All who were associated with him mourn the passing of a beloved friend and of a great character. It is one of the minor tragedies of the war that such a man should have ended his days in comparative obscurity, far from his native land, even though among friends.—J. S. H.

The Services

The Efficiency Decoration of the Territorial Army has been conferred upon the following officers: Col. C. H. Carlton, M.C., Lieut.-Col. (Hon. Col.) R. M. Savey, O.B.E., M.C., Majors (Hon. Lieut.-Cols.) R. B. Brew, W. S. Harvey, and F. R. Langmaid, Majors (Temp. Lieut.-Cols.) E. G. Gerstenberg, and B. M. Nicol, Majors T. A. Danby, J. D. A. Gray, and H. R. R. Mavor, Capt. (Hon. Major) L. P. Clarke, and Capt. (Temp. Major) T. H. Coan, M.M., R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Killed.—Temp. Lieut.-Col. Andrew Robert Fausset Clarke, M.C., Temp. Major Clifford Longden Lewis, and War Subs. Capt. Roylance Lynton Parkinson, R.A.M.C.

Previously reported missing, now reported killed.—War Subs. Capt. John Varley Schofield, R.A.M.C.

Died.—Lieut.-Col. Edward Alexander Strachan, Major Murdo Buchanan, Temp. Major Ewen Arthur Elson Palmer, War Subs. Major Hamish Barrowman, and War Subs. Capt. James Lavington Ashley, Archibald David Morrison King, Wilfred Kendrick Lloyd, Margaret Mary Loughnan, and Alan Ross Sheriff, R.A.M.C.

Died as Prisoner of War.—War Subs. Capt. William Service Aird, R.A.M.C.

Previously reported Prisoner of War, now reported Died as Prisoner of War.—Lieut.-Col. Cyril Armstrong, M.B.E., and War Subs. Capt. Alfred Kenneth Eastwood, Basil Frederick Benhow Gulliver, M.C., and Arthur Wemyss Gordon Sutherland, R.A.M.C.

Wounded.—Temp. Lieut.-Col. A. G. Fergusson, Major Hilda Roberts, and War Subs. Capt. J. K. A. Burn, R.A.M.C.

Medical News

Dr. D. Evan Bedford will deliver the Bradshaw Lecture on Thursday, Nov. 7, at 5 p.m., at the Royal College of Physicians, on "Hypertensive Heart Disease."

The inaugural address at the opening of the 210th session of the Royal Medical Society of Edinburgh will be given by Sir Henry Wade at 7, Melbourne Place, on Friday, Oct. 11, at 8 p.m. He will speak on "The Life of an Edinburgh Medical Student 300 Years Ago." The provisional programme for the session includes addresses by Mr. P. H. Mitchiner on Oct. 25, "The Aftermath of War in Medicine"; by Dr. J. R. Rees, on Nov. 8, "Social Psychiatry and Medical Progress"; by Dr. John McMichael, Nov. 22, "Heart Failure"; Col. L. W. Harrison, Dec. 6, "Half a Lifetime in V.D.: from Chaos to Order"; Prof. Charles Cameron, Jan. 10, "Tuberculosis as a Problem in Diagnosis"; Mr. A. H. McIndoe, Jan. 24, "The Surgery of Congenital Defects"; and Dr. R. W. Durand, Feb. 14, "The Doctor, the Patient, and the Law."

The annual general meeting of the Heberden Society has been arranged for Friday and Saturday, Oct. 25 and 26, at 11, Chandos Street, Cavendish Square, W. After the business meeting at 4.30 p.m. on Friday a discussion on future trends of research in rheumatoid arthritis will be opened by Dr. G. M. Findlay with a paper on arthritis in rats and mice due to pleuropneumonia-like organisms, followed by Dr. D. H. Collins, on erysipelotheix polyarthritis of swine. The annual dinner will be held at the Euston Hotel that evening at 7.45. On Saturday at 11 a.m. Prof. J. Axel Höjer, chief medical officer, Royal Swedish Ministry of Health, will give an address on the organization and work of a rheumatic service in Sweden.

Dr. Ludo van Bogaert of Antwerp will give a lecture at the National Hospital, Queen Square, Medical School, on Wednesday, Oct. 9, at 4 p.m., on "Progressive Atrophies of the Globus Pallidus, their Clinical and Pathological Characters." All those interested are invited.

The British Institute of Philosophy has arranged a course of lectures on "Contemporary World-Outlooks" beginning on Friday, Oct. 11, at 5.15 p.m. Particulars may be had from the Director of Studies, University Hall, 14, Gordon Square, London, W.C.1.

The British Red Cross Society, working in close co-operation with the Ministry of Health, held a blood transfusion conference at Gas Industry House (opposite St. George's Hospital) on Sept. 24.

According to the *Manchester Guardian* of Oct. 1 almost the entire medical staff of two of Stockholm's hospitals decided to strike at midnight to-night against a Government decision forbidding them to charge for health certificates. The two hospitals have a daily average of nearly 3,000 in-patients and out-patients. The doctors say they will treat patients already in the hospital, but they will accept no new patients, nor will they treat out-patients.

At a meeting of the Lausanne Medical Graduates' Association held in London on Sept. 25 Dr. Cyril T. Gasking, of Harrogate, was elected president for 1946-8, and Lieut.-Col. Colin McIver, of Bexhill, president-elect for 1948-50. The following officers were re-elected: vice-president, Dr. Robert Fleming, of Harrow; hon. secretary and treasurer, Dr. Charles A. H. Franklyn, Wickham Hill House, Hassocks, Sussex, to whom all inquiries should be sent.

The permanent headquarters and address of the United Nations Educational, Scientific, and Cultural Organization are now UNESCO House, 19, Avenue Kléber, Paris, 16^e, France.

Before the war a blind one-armed Englishman was a teacher of English in Holland. During the Arnheim fighting his home and all his effects were destroyed, and for seven weeks he wandered homeless about the countryside. But misfortunes failed to break his spirit, and his cheerfulness impressed all who met him. He has now started afresh, and the British Wireless for the Blind Fund has sent him a new wireless set to replace the one he lost in the war.

Mr. A. E. Porritt, C.B.E., is by invitation shortly taking over the duties of Professor of Surgery at Harvard University for a few weeks.

Mr. W. A. Macleod, of 17, Gayton Road, Harrow-on-the-Hill, who died on May 7 last, with net personalty of £19,720 9s. 8d. bequeathed six-twentieths of the residue of the property to the Lister Institute of Preventive Medicine, London, or to the University of Edinburgh if the former is no longer functioning or no longer carrying out research, upon trust to found a scholarship or scholarships or other form of award in memory of his daughter Morna, which shall be known as "The Morna Macleod" scholarship or award, and be "tenable by students of Scottish birth or descent on at least one side of their family."

Dr. Ernest Chittenden Bridges, of 67, Harcourt Terrace, London, S.W.10, died on April 17 last, leaving £59,113 14s. 4d. gross, with net personalty £58,982 6s. He left £500, wearing apparel, and suitcases to the Royal Medical Benevolent Fund; £25 to the St. Alban's Medical Club, of which he had been president; and £25 to the Medical Society of London.

EPIDEMIOLOGICAL NOTES

Paratyphoid

At Coatbridge, in Lanarkshire, there have been a further 11 cases of paratyphoid B. In the preceding fortnight 113 cases were reported in this town.

Halifax C.B. has had another 7 cases of paratyphoid in the week under review, as against 14 cases in the preceding week.

Discussion of Table

In *England and Wales* infectious diseases were less prevalent. There were fewer cases of measles 108, whooping-cough 80, diphtheria 29, and dysentery 18. The only exception to the general trend was a rise of 123 in the notifications of scarlet fever.

A slight rise in the incidence of scarlet fever was general throughout the country; the largest local increase was London 24. Changes in the returns for measles were a decrease in Lancashire 51 and a rise in Yorkshire West Riding 33. Very little alteration was recorded in the incidence of whooping-cough, and the only variations of note were decreases in Warwickshire 44 and Lancashire 44. The largest of the local fluctuations in diphtheria was a decrease of 11 in Durham. One-quarter of the total of 68 cases of dysentery were notified in London.

In *Scotland* rises were reported in the incidence of scarlet fever 13 and diphtheria 5, and a fall of 20 in the notifications of whooping-cough. The largest returns of dysentery were Glasgow 11, Edinburgh 9, and Aberdeen 9.

In *Eire* an increase of 4 was recorded in the notifications of diphtheria, but Dublin C.B. had a rise of 12. Diarrhoea and enteritis was less prevalent; there were 15 fewer cases than in the preceding week. Of the 55 cases of diarrhoea and enteritis 46 were notified in Dublin C.B.

In *Northern Ireland* little change occurred in the trends of infectious diseases. The chief feature of the returns was an outbreak of diphtheria involving 6 persons in Londonderry R.D.

Week Ending September 21

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 853, whooping-cough 1,610, diphtheria 240, measles 1,208, acute pneumonia 312, cerebrospinal fever 36, dysentery 66, acute poliomyelitis 28, paratyphoid 17, typhoid 13.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Sept. 1

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

ANY QUESTIONS?

Prostigmin Test for Pregnancy

Q.—*What is the rationale of the prostigmin test for pregnancy? Is it considered to be of any practical value, particularly in the early days of pregnancy?*

A.—Prostigmin is a synthetic parasympathetic stimulant with a similar action to that of physostigmine or eserine. It acts in the body by inhibiting acetylcholine esterase and thus facilitating the action of acetylcholine on the tissues. Soskin, Wachtel, and Hechter (*J. Amer. med. Ass.*, 1940, 114, 2,090) first introduced the use of prostigmin for the treatment of delayed menstruation and claimed that a menstrual flow was induced in most cases, provided the patient was not pregnant. Haig Carapetyan (*J. Amer. med. Ass.*, 1943, 122, 81) has suggested as explanation for this effect of prostigmin in delayed menstruation that it increased the amount of acetylcholine in the uterine tissues and thus promoted the hyperaemia which normally precedes menstruation and is believed to be brought about by oestrogenic hormone.

L. B. Winkelstein (*Amer. J. Obstet. Gynec.*, 1942, 44, 231) found that injection of prostigmin successfully differentiated early pregnancy from temporary amenorrhoea by inducing menstruation in eighty-seven out of ninety cases. The number of daily injections of one to two ml. of a 1:2,000 solution of prostigmin methyl sulphate required was, on average, 2.4. He found, however, that some patients, who were subsequently found to be pregnant, bled following the injections and that other patients who were not pregnant did not respond. There is therefore a definite danger of causing early abortion. Winkelstein considers that as a *diagnostic* procedure administration of prostigmin is of little value, though he suggests it may be of use in the treatment of temporary amenorrhoea in cases where pregnancy has been definitely excluded and there is no obvious endocrine disorder.

Simple Haemoglobin Estimation

Q.—*Would you please describe a method of haemoglobin estimation which could be used in a country district without any laboratory facilities.*

A.—A number of methods are available for the simple estimation of haemoglobin in a country district, each one having its advantages and disadvantages. Taking all factors into consideration Sahli's method is still probably the best available. The principle of this method is the conversion of the haemoglobin in a known quantity of blood to acid haematin by adding the blood to hydrochloric acid and comparing the mixture with a standard colour tube.

Materials.—(1) Sahli's haemometer, consisting of a comparator frame, a standard colour tube (preferably of solid glass), and a graduated tube of the same bore, obtainable from Hawksley and Son, New Cavendish Street, London, W.1. (2) Decinormal hydrochloric acid (approx. 1% conc. HCl), obtainable from any chemist.

Method.—The HCl is placed in the graduated tube up to the mark 10. The pipette is filled to the 20 c.mm. mark with blood; the contents are gently blown into the acid and the pipette washed out by alternately sucking up and expelling the acid. The complete conversion of the haemoglobin to the brown acid haematin takes approximately thirty minutes, but

as the great bulk of the change is complete in ten minutes this latter time can be taken as accurate enough for clinical purposes in general practice. Distilled water is now added drop by drop to the graduated tube, and the contents mixed between each addition by placing the thumb over the end of the tube and inverting. When the colour of the contents of the graduated tube exactly matches the standard tube the figure on the graduated tube gives the haemoglobin content of the blood.

Meaning of Allergy

Q.—*Will you kindly tell me what is the origin or derivation of allergy and allergic?*

A.—The word allergy is derived from the Greek words *allos* (different or changed) and *ergon* (energy or activity), and thus means a changed or altered activity. It was coined by von Pirquet, a Viennese physician, in 1906, who implied an antigen-antibody reaction as its basis. It did not come into clinical use until after its adoption and modification in 1912 by Doerr, who worked with von Pirquet. Doerr included in his definition all forms of altered reactive capacity irrespective of the presence or absence of an antigen-antibody reaction, that is, all abnormal and specific reactions of the body to foreign, ordinarily innocuous, substances. American workers have contributed very largely to our knowledge of the part played by allergic reactions in clinical medicine, and their publications are responsible for its present fairly general acceptance as a term denoting all forms of hypersensitivity occurring naturally, particularly in man.

The clinical manifestation varies according to its location and may result in asthma, hay fever, urticaria, eczema, migraine, gastro-intestinal disturbances, etc.

Treatment of Tongue-tie

Q.—*Please describe the operation for "tongue-tie" in children.*

A.—Before operating for tongue-tie one must make quite sure that the operation is necessary. Gone are the days (we hope) when mother, midwife, or even doctor too easily diagnosed such a condition and too readily snipped the short fraenum of the tongue. It is still a common mistaken diagnosis to attribute defective speech or difficulty in suckling to a tongue-tie. Nevertheless there are occasional cases in which the fraenum linguae binds down the tip of the tongue so that it cannot be protruded beyond the teeth or lips and thus may interfere with proper suckling. Only in these cases is it necessary or wise to divide the fraenum.

The operation of division of the contracted fraenum should be done by snipping it with a pair of blunt-pointed scissors directed downwards and towards the symphysis menti; the fraenum is made evident by elevating the tip of the tongue by two fingers of the left hand while the scissors are held in the right hand. If a common director is at hand one may utilize the slit in its splayed end to steady the fraenum while it is being divided. The cut should not be more than sufficient to divide the double fold of mucosa, but the tip of the tongue may further be freed by pressure with the forefinger. Indeed, Fitzwilliams states: "all that is necessary if the fraenum is tight is to make pressure on the fraenum immediately behind the jaw and it will be felt to give from the gum." Whichever method be employed one must ligate any bleeding point, and some prefer to put a transverse catgut suture to draw the raw surfaces together. In infants no anaesthetic is necessary; in older children one may infiltrate with a dilute solution of novocain.

Marriage and Syphilis

Q.—*A young woman of 23 wishes to get married. In 1943 she was found to have syphilis (acquired), and was treated by a single intensive course of N.A.B. and bismuth. Since then she has had quarterly blood examinations—all negative. What is one to advise her about marriage and pregnancy? Will anti-luetic treatment be required during her future pregnancies?*

A.—There is no reason why this girl should not marry, but it is usual to advise deferment of marriage till five years have elapsed since the date of infection. The amount of treatment seems to have been small, but seeing that blood tests have

been consistently negative for approximately three years the chances of her being "cured" seem to be good. If she marries soon she should avoid "unprotected" sexual intercourse till 1948. If and when she does become pregnant she should receive antisyphilitic treatment throughout *each* pregnancy—in any case before the fifth month—and carry it on right up to term. The risk of conveying infection to the husband is negligible after five years, while that of producing a congenitally syphilitic child lasts indefinitely; but adequate treatment of the mother during pregnancy should ensure the birth of a healthy child in more than 90% of cases.

Workmen's Compensation Act

Q.—*The principal, Dr. A., employs two assistants, Dr. X. and Dr. Y. Doctors X. and Y., while driving a motor-car together to visit a patient, are involved in a road accident. Dr. X. is killed instantly. Dr. Y. loses the sight of one eye, but is able to resume his duties under physical handicap after a period of three months. What compensation claims are representatives of both parties entitled to lodge against Dr. A. under the Workmen's Compensation Act?*

A.—To qualify for workman's compensation the applicant must be engaged in a contract of service, and his remuneration must not exceed £420. The minimum compensation awarded in respect of a death is £300; if the man was married with children it may rise to £700 according to the degree of dependency. Compensation for injury depends on degree of impairment of earning capacity, and if the parties cannot agree the issue is tried by a county court judge (or sheriff in Scotland) sitting as an arbitrator. The maximum award for a single man is 40s. a week; this also is increased if the applicant has dependants.

Pelvic Cellulitis

Q.—*A patient had a pelvic cellulitis after child-birth fourteen years ago. This was treated conservatively. Since then she has had periodical "flare-ups" of the infection. What is the value of penicillin in such cases, and what dosage is suggested?*

A.—On the data given it would certainly seem reasonable to try penicillin in this case, while giving a guarded prognosis. It has been found that chronic cases of gonorrhoea and of other types of pelvic infection may clear up on penicillin therapy when other means have failed. The reason why penicillin may fail in such a case as that described is that the infecting organism—if indeed any can be demonstrated after so long a lapse of time—is likely to be a coliform organism, and these are generally insensitive to penicillin. The local physical signs should be carefully assessed before commencing treatment, and any cervicitis should be treated first with the electric cautery. Large doses are recommended for cases of this type—two or three million units—and this would be best given by intramuscular injection of the saline solution, 30,000–40,000 units every three hours, day and night, for seven or eight days. A course of pelvic diathermy often brings relief in cases of chronic pelvic infection and might be tried if other treatment is unsuccessful. If this fails and the attacks persist, patient would almost certainly benefit by a total hysterectomy with removal of both tubes, but conserving some ovarian function if the patient has not reached menopausal age.

Secondary and Latent Syphilis

Q.—*(a) Is the blood Wassermann reaction invariably positive in secondary syphilis? (b) Is a "provocative" dose of N.A.B. justified in a case clinically resembling secondary syphilis, but with a negative Wassermann reaction? (c) What is latent syphilis? (d) What is the minimum amount of penicillin that can convert a positive Wassermann to a negative one?*

A.—*(a)* The blood Wassermann reaction is positive in well over 99% of cases of untreated secondary syphilis; it is so consistently positive that a negative report demands a repeated test and raises the suspicion of a technical error.

(b) "Provocative" injections of neoarsphenamine are nowadays considered by most authorities to be valueless. In a case of florid secondary syphilis which has received no treatment it should be possible to demonstrate *Spirochaeta pallida* in some of the surface lesions or, failing this, by gland puncture.

Blood tests should be repeated and include both complement fixation and flocculation tests.

(c) Latent syphilis is, essentially, syphilis without physical signs: Stokes defines it as "seropositive, otherwise asymptomatic, syphilis," but adds that latency may "best be described not as an asymptomatic lull preparatory to destructive late manifestations but as a period of high resistance and low virulence, with an undercurrent of chronic mild inflammatory change in vital structures and an upper stratum of alternating relapse and recovery."

(d) It is not known what is the *minimum* amount of penicillin which will convert a positive Wassermann to negative: as little as 60,000 Oxford units have been reported as accomplishing this. Much, however, depends on three factors: (1) the strength of the serum reaction; (2) the age of the disease; and (3) the type of penicillin employed. In general, the stronger the serum reaction and the longer the disease has existed the greater the amount of penicillin required; quite small amounts will often reverse a reaction in primary syphilis, whereas amounts up to ten million units or more frequently fail in late or latent syphilis. Many of the most recently manufactured samples of penicillin seem to be less spirochaetocidal and less effective in reversing serum reactions than those produced before the middle of 1944.

INCOME TAX

Car Transactions

F.F.'s pre-war car was "blitzed" in 1943. He bought a new car in November, 1945, for £397, and as from January 1, 1946, took an appointment (residing on the premises) which allowed him to do a certain amount of private work. What deduction can he claim in respect of the car?

* No allowance can be claimed against the salary from the appointment. As regards the private work a proportion of the car expenses and depreciation, etc., can be claimed, according to the ratio of that use to the total use of the car—e.g., on a mileage basis. The full depreciation allowance for the year to April 5, 1947, would be:

Capital allowance, 20% of £400	£80
Wear and tear allowance, 25% of £400	100
Total	£180

A.H. has had several car transactions over the past four years: those referred to below are relevant to income tax deductions for 1946–7 and the future. Car A was bought in 1940 for £40, and sold on Aug. 17, 1946, for £100. On the same day car C was bought for £650.

* 1946–7.—Depreciation at 25% on the value of Car A as written down by the 1945–6 income tax depreciation will be due. 1947–8.—(a) An initial allowance on car C at 20%, and (b) depreciation on the car at 25% will be due.

New Appointment as Assistant

J.F. is married with two children and is taking an assistantship as from Oct. 1, 1946, at a salary of £700 plus £200 car allowance. (It is understood that he was previously doing postgraduate work and it is assumed that he had no taxable earnings in the six months to Oct. 1.) He asks what deductions will be made under P.A.Y.E. and what car expenses he can claim.

* On the above basis J.F.'s taxable earnings for the year to April 5, 1947, will be £350. Against that he is entitled to the following allowances:

Personal allowance	£
Child allowance	180
Earned income relief (1/8)	47
Total	£327

The total tax payable for the year will therefore be £23 at 6s. 1d., i.e. £6 18s. He is advised to put himself in communication with the local Tax Office so that his principal can be enabled to make the correct deductions. The car allowance of £200 is, we consider, unlikely to be questioned by the Tax Office provided that J.F. makes no claim to deductions for depreciation and running costs. Whether it would pay him to accept a smaller allowance with consequent increase in salary and claim depreciation, etc., depends on the cost of the car he buys and the extent to which it is used for non-professional purposes. No deduction is apparently due for the rent of £40 paid for his residence.

LETTERS, NOTES, ETC.

The Development of a "Cottage Hospital"

Dr. J. WALLACE KEMP (Kingston) writes: Twenty-five years ago the Kingston-upon-Thames Victoria Hospital was a cottage hospital, conducted and functioning as such. A constructive policy was instituted by the then members of the medical staff. The wards were rebuilt, a children's ward added and a new operating theatre built. This is now a modern, well-equipped department in daily use for major and minor operations. The x-ray department was extended, a new apparatus installed, and a radiologist appointed. Cases are referred to the department from outlying areas, and the attention given is much appreciated. As the scope of the hospital expanded additions were made to the honorary consulting staff, and weekly attendances are now made by a consulting surgeon, an ophthalmic surgeon, a gynaecologist, an ear, nose and throat surgeon, and a consulting physician to see out-patients referred by members of the staff, or to operate if required. All these consultants are of high standing in the medical and surgical profession. An honorary anaesthetist was also appointed. A pathological laboratory was established some years ago. A block of private wards has been added to the original building. There has been a progressive and consistent transition from the original cottage hospital status to its present high standard of efficiency and utility. Staffed, as it is, by consultants of high standing and general practitioners of wide experience, the reputation of the hospital is a testimonial to the committee who have conducted its administration and to the members, consultant and general, who have applied their knowledge and skill in raising its status to what may be fairly described as a "practitioner general hospital." There appears to be a need for hospitals of this type and the Kingston Victoria might well be adopted as a model for such institutions. The preservation of "follow up" contact between the patient and doctor is of inestimable value in cases requiring operation, always a crisis in the life of the individual and of their families. With their own experience and the advice of consultants the limitations of the hospital are fully recognized, and in certain instances arrangements are made for more expert treatment elsewhere, but this is exceptional.

Pipe versus Cigarette

Dr. S. A. W. RUSHBROOKE (Shebbear, Devon) writes: One other aspect of the problem. Doubtless in every case dilute nicotine vapour is absorbed into the blood stream producing transient and varying effects in every type of individual. Much more nicotine is absorbed in cigar smoking and its effects are usually readily noticeable to the casual smoker of cigars, and, of course, the stronger the cigar the quicker the effects. The smoker of both pipe and cigarette usually prefers the former, and providing the pipe is clean and dry—and this is important—tobacco smoked this way is more enjoyable, and indeed is to be preferred. The cigarette usually contains a finer tobacco, and invariably smaller particles, even dust, capable of being inhaled, thus adding to the irritation and inducing the cough. No matter how good the cigarettes are the main reason why the continued smoking of them results in the familiar smoker's cough and throat is because trouble lies far more in the paper than the tobacco. Even if the best rice paper is used the acrid vapours produced from the continuous smouldering carbohydrate in the paper itself are probably the real underlying cause of the smoker's cough, acting as an irritant in the lungs. Gastric disturbances are further set up by the same cause by absorption in the stomach glands and nerve endings of the mucosa inhibiting the natural flow of gastric juices, thus contributing to at least one common form of dyspepsia. Hence the advice not to smoke immediately before a meal and for half an hour after its consumption is physiologically sound and has proved helpful to many.

Two Kinds of Cold?

Prof. W. BURRIDGE writes from the Department of Physiology, Rangoon: In Lucknow my house was just over a furlong from my laboratory. The latter was on the higher ground, and to reach it I had to traverse a flight of steps arranged in one group of four, three of sixteen, and one of fifteen. They were easy steps since the tread was two bricks broad and one brick on its side high. In the flush of the early morning I was accustomed to take these steps two at a time, and could do so comfortably. But there would come some mornings when after completing the hundred paces or so from the top of the steps to the laboratory entrance I arrived out of breath. In due course I found that this shortness of breath heralded a cold which would arrive three days later. This cold I could not cure. Treatment with aspirin, for example, would bring me nearer to drowning in my own secretions than any form of relief. It started in the nasal cavity and then "went down" to become a sort of "orrid 'acker." It could be well described as a bronchitis that did not incapacitate. The act of coughing, however, was painful enough to induce me to resort to opium. The total duration would be about one month. Recently I found it to be

amenable to sulphonamides. But also during the cold weather there would be other occasions when, except for that preliminary bout of shortness of breath, I found signs that a "cold" was coming. My standby for this was the unguentum A B C of Guy's Hospital plus a throat spray. Such colds could be nipped in the bud, as it were. I have therefore to plead for the recognition of two types of common cold, the one that can be aborted and the one that cannot. The colds that can be cured are of the one type, the colds that must be endured are of the other. Recognition of their existence, however, should make considerable difference to conclusions relative to the prevention of colds. Doubtless there are many other doctors who can make daily test of their physical fitness by climbing quickly enough some flight of stairs which they regularly meet on their daily rounds, and who may be able to report at the end of the "cold" season on colds that can be aborted and colds that cannot.

Village Longevity

Dr. G. R. A. ARMSTRONG (Stourport-on-Severn) writes: I have been much interested in the longevity records of Dr. C. E. S. Harris (May 4, p. 709) and of my fairly near neighbour Dr. A. C. L'Estrange (June 1, p. 864). Until a week ago I had seven patients whose ages totalled 638 years. One aged 90 comes to my surgery weekly very dapper, upright, sprightly, and mentally alert; another aged 91 was in the Birmingham City Police for twenty-six years and has been forty-two years on pension practising vegetable and fruit growing locally, but this year "the rheumatics went to his back" so he has "retired" to Birmingham again. The year 1859 must have been a vintage year as I have eleven patients (two of them attend my surgery) each aged 87 years. There must be some truth in a local saying: "They'm don't die hereabouts, we'm takes 'em to Bewdley and shoots 'em."

The Tobacco Habit

Dr. G. DEERY (Plymouth) writes: Under "Any Questions?" (Aug. 24, p. 284) it is suggested that pipe sucking is resorted to as a substitute for the mother's breast. Is it a reasonable and analogous deduction that when we draw up our knees beneath the blankets on a cold night we are merely reverting to the position *in utero* where presumably we were cosy and warm?

Dr. REGINALD H. LITTLE (Ringwood) writes: The answer given to a question concerning the tobacco habit which was published in the *Journal* (Aug. 24, p. 284) reveals a state of mind which one would hardly credit even in a psychologist. For absolute and utter rubbish and jargon it would take a lot of beating. To carry this nonsense further we shall soon be told by the experts that human milk can be had in brands like Players or Gold Flake. That smoking should be regarded as a "solace for loss of love" must shake some of us when cigarettes and tobacco are in short supply. Surely the answer is very simple, and I venture to suggest that smokers carry on their vice because they like it and for no deeply veiled oral erotic tendency.

Painless Labour

Dr. L. G. HIGGINS (Woking) writes: Will you allow me to add a further note to the answer given to your correspondent who seeks confirmation of the benefit of Dr. Grantly Dick Read's procedures for the conduct of pregnancy and labour (Sept. 14, p. 407)? I have known Dr. Dick Read for many years, and can claim to be familiar with the principles of his teaching. Painless labour may possibly occur as a great rarity, but to claim that any method of delivery can "ensure painless childbirth" sounds too much like witchcraft. It is more correct to say, as I can truly affirm, that a girl, properly prepared and with a favourable presentation, should achieve a normal delivery with some effort of concentration, some discomfort, and often some pain at the end of the first stage of labour. But the pain or discomfort will be cheerfully borne and the patient should remain calm and composed, without anxiety or distress. The labour loses altogether the character of an ordeal of physical endurance, and the whole experience becomes interesting and enjoyable. In a successful case, the simplicity of the actual delivery is striking, bringing to the mother feelings of satisfying achievement and gratitude which are moving to witness.

A Rowlandson Print

Dr. HUBERT H. DU BOULAY (Chandlers Ford, Hants) writes: Can anyone give the names of a group of doctors, probably surgeons, one of whom is amputating a leg with an ordinary carpenter's hand-saw, figured by T. Rowlandson in a coloured caricature print dated 1785? The British Museum, the Wellcome Historical Museum, and the Royal College of Surgeons are unable to help.

Correction

In a letter on the early treatment of ocular defects by Mr. Sydney Tibbles (Sept. 28, p. 475) a reference to "the 1914-18 war" should have read "1939-45 war."

Association Notices

AREAS OF SWINDON AND TROWBRIDGE
DIVISIONS

Notice is hereby given by the Council of the British Medical Association to all concerned that it is proposed to transfer the municipal borough of Malmesbury from the area of the Swindon Division to that of the Trowbridge Division.

Any member affected by this proposal and objecting thereto is requested to write to the Secretary of the Association by Oct. 19, 1946, stating the objection and the ground therefor.

CHARLES HILL,
Secretary.

Sept. 21, 1946.

Ophthalmic Group Committee: Correction

A correction is necessary in the list of members of Committees published on Sept. 7 (p. 77). We have been informed by the Faculty of Ophthalmologists that the names of the six members of the Ophthalmic Group Committee appointed by the Council of the Faculty of Ophthalmologists should be:

Mr. J. D. M. Cardell, London.
Mr. J. H. Doggart, London.
Mr. R. Affleck Greaves, London.
Mr. E. F. King, London.
Mr. F. W. Law, London.
Mr. J. N. Tennent, Glasgow.

Hospitals Committee: Correction

Add: "One member to be appointed by the Association of Municipal Specialists."

Diary of Central Meetings

OCTOBER

17. Thurs. Publishing Subcommittee, 11 a.m.
Journal Committee, 2 p.m.

Branch and Division Meetings to be Held

COVENTRY DIVISION.—At Coventry and Warwickshire Hospital, Tuesday, Oct. 8, 8.30 p.m. Discussion on the Relationship between the Industrial Medical Officer and the General Practitioner, with reference to the case of open tuberculosis, to be opened by Dr. A. D. Macdonald.

EAST KENT DIVISION.—At St. George's Hotel, Cliftonville, Thursday, Oct. 10, 8.30 p.m. Address by Dr. I. B. Morris.

EAST YORKSHIRE BRANCH.—At "Quern House," Park Street, Hull, Tuesday, Oct. 8, 8.30 p.m. Lecture by Prof. Alan Moncrieff: Child Health.

RICHMOND DIVISION.—At Richmond Royal Hospital, Friday, Oct. 11, 9 p.m. Dr. Gerald Slot, "Recent Advances in Medical Therapeutics."

Meetings of Branches and Divisions

BATH DIVISION

A meeting of the Bath Division was held on Sept. 25, with Dr. G. D. Steven in the chair, when the following resolution was passed unanimously:

That this meeting strongly recommends to the Council that, in implementing the resolution of the Representative Body (carried on July 24, 1946) to take a referendum of the whole profession on the simple issue of whether negotiations with the Minister should take place or not, the referendum should take the following form:

Three separate forms of different colours should be sent to each member of the profession. One form would be headed "Public Services Section," the second "Consultant and/or Specialist Service," and the third "General Practitioner Service." Each form should ask the simple question—"Do you agree to negotiations on regulations on this Section being carried out with the Minister?" Every member of the profession should be asked to return only the form which refers to the Section to which he or she predominantly belongs.

MALAYA BRANCH

A clinical meeting of the Southern Division, Malaya Branch, was held on July 31, 1946. The subject under discussion was penicillin, and Dr. E. C. Davies, Lieut.-Col. French, and Lieut.-Col. Harris spoke. The attendance was 84.

All general practitioners in Singapore will be able to obtain a text book from the Controller of Supplies provided they are sponsored by the Association. The hon. secretary of the Southern Division has undertaken to compile a list of those anxious to receive such text books and when complete will arrange for supply to be made.

POSTGRADUATE NEWS

The Fellowship of Medicine announces: (1) Obstetrics and gynaecology, for general practitioners, daily, Oct. 14 to 19, at Queen Charlotte's Maternity Hospital, and Chelsea Hospital for Women. (2) Week-end course in rheumatism, all day Saturday and Sunday, Oct. 26 and 27, at St. Stephen's Hospital, Fulham Road, S.W.

The University of Leeds Postgraduate Subcommittee announces that it is proposed to hold a two-weeks general refresher course for Class II demobilized medical officers and insurance practitioners, beginning on Monday, Nov. 25. Applications and inquiries should be addressed to the Senior Administrative Officer, School of Medicine, Leeds.

WEEKLY POSTGRADUATE DIARY

BLACKPOOL: VICTORIA HOSPITAL.—Thurs., 8 p.m., Dr. Cross: Radiotherapy in Gynaecology.

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—Wed., 8 p.m., Dr. Michaelson: Proptosis and Exophthalmos.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—Tues., 5 p.m. Dr. A. C. Roxburgh, Cutaneous Syphilis. Thurs., 5 p.m. Dr. H. MacCormac, Industrial Dermatitis.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Experimental Medicine and Therapeutics.—Tues., 5.30 p.m. Presidential Address by Prof. H. P. Himsworth: Protein Metabolism in Relation to Disease.

Section of Psychiatry.—Tues., 5.30 p.m. Presidential Address by Prof. Aubrey Lewis: The Education of Psychiatrists.

Section of Physical Medicine.—Wed., 4.30 p.m. Presidential Address by Dr. F. S. Cooksey: The Planning and Organization of Physical Medicine Departments.

Section of Ophthalmology.—Thurs., 5 p.m. (Cases at 4.30 p.m.) Presidential Address by Mr. A. H. Levy: The Aesthetics of Vision. Paper by Mr. John Foster: An Ophthalmic Tour in France and Switzerland.

Clinical Section.—Fri., 5 p.m. (Cases at 4 p.m.)

CHELSEA CLINICAL SOCIETY.—At South Kensington Hotel, Queen's Gate Terrace, Tues., 7 p.m. Dinner meeting. Dr. R. Jarman: Modern Anaesthesia.

APPOINTMENTS

ADDENBROOK'S HOSPITAL, CAMBRIDGE.—Honorary staff appointments: Radiologist, F. R. Berridge, M.B., D.M.R., Surgeon to the Gynaecological and Obstetrical Departments, Oswald Lloyd, M.D., F.R.C.S. Physician, Laurence Martin, M.D., M.R.C.P., Surgeon, B. M. Truscott, M.B.E., M.B., F.R.C.S. Ophthalmic Surgeon, G. F. Wright, M.B., D.O.M.S.

BOLTON ROYAL INFIRMARY.—Honorary Physicians, A. Ingham, M.B., and H. Philip Goldman, M.B., M.R.C.P.

DAY, F. M., M.R.C.S., D.P.H., Medical Officer of Health, Metropolitan Borough of Hammersmith.

EDINBURGH UNIVERSITY.—D. M. Douglas, Ch.M., F.R.C.S., lecturer in experimental surgery, University of Edinburgh, deputy director, Wilkie Surgical Research Laboratory, and associate assistant surgeon, Royal Infirmary, Edinburgh.

ROYAL LIVERPOOL UNITED HOSPITAL.—Appointments to Honorary Medical and Surgical Staff at Liverpool Royal Infirmary: Dental Surgeon, G. Graham Macphree, M.D., L.D.S., Assistant Physician for Tropical Diseases, D. R. Seaton, M.B., D.T.M., D.P.H., Radiologist, P. H. Whitaker, M.D., D.M.R.E. Dermatologist, G. W. Bamber, M.D., F.R.C.P.

ST. THOMAS' HOSPITAL, S.E.—Honorary appointments. Obstetric Physician, R. K. Bowes, M.D., M.S., F.R.C.S. Orthopaedic Surgeon, G. Perkins, M.Ch., F.R.C.S.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

CAIRNS.—On July 12, 1946, at Kingston-on-Thames, to Theresa, wife of Dr. R. J. Cairns, a son—Andrew John.

EARDLEY.—On September 21, 1946, at 23, Keishley Road, Colne, Lancs., to Catherine Vera, wife of A. W. R. Eardley, M.B., Ch.B. (Sheff., 1931), twin—Alan Christopher Stenton and Catherine Rosalind.

JACOBS.—On September 22, 1946, at Hammersmith Hospital, to the wife of Dr. A. L. Jacobs (Dr. Lucia Frank), a daughter.

ORTON.—On September 26, 1946, to Drs. Richard and Betty Orton, 30, Cornwallis Crescent, Clifton, Bristol, a daughter.

MARRIAGE

EDWARDS—ADAMS.—On September 17, 1946, at Stenhouse Church, East Fife, Edwards, A.D. Corps, of "Invervar," Laureb, Stirlingshire, to Capt. G. Adams, R.A.M.C., of Blackstone House, Broughane, Ballymena, N. Ireland.

DEATHS

ELLIOT.—On September 7, 1946, Henry P. Elliot, born 1871, M.B., Ch.B. 1904, Queensland ad eum grad. Practised mostly in Australia for 51 years.

EVANS.—On September 26, 1946, at Oxford, Brenda, wife of Gordon Evans, M.B., B.S.

LONDON SATURDAY OCTOBER 12 1946

BEFORE AND AFTER MORTON

A HISTORICAL SURVEY OF ANAESTHESIA

BY

E. ASHWORTH UNDERWOOD, M.A., B.Sc., M.D., D.P.H.

Director of the Wellcome Historical Medical Museum

On October 16, 1946, the world will celebrate the centenary of the advent of surgical anaesthesia as a practical measure. The man was W. T. G. Morton; the country, the United States of America. As in the case of most great practical discoveries, there had been forerunners who, with little success themselves, laid the stepping-stones without which the stream dividing the impracticable from the practicable could not have been crossed. Many of these forerunners were British, and it is a happy coincidence that the city in which Morton's courage enabled him to succeed in the supreme test was Boston, Massachusetts—named after its spiritual parent in East Anglia. But Morton's success was not due to a lucky accident. His immediate predecessors were all American. Leake (1945) has recently suggested that it was not by chance that the problem happened to be solved on the other side of the Atlantic, since in 1846 the American nation was still partly in the pioneering state; and since the chief problems in medical practice were surgical, surgeons were always on the watch for something to relieve the pain which hampered their operations. It is perhaps more probable, however, that America succeeded because her surgeons were not so fettered by the long tradition of necessarily painful operations which was the heritage of the Old World.

The occasion is fitting for a brief review of man's efforts to prevent—or at least obtund—the pain of surgical procedures.

History of the Term "Anaesthesia"

The *New English Dictionary* (Oxford) indicates that the word was first used by Bailey in 1721 as meaning "a Defect of Sensation as in Paralytic and Blasted Persons." In 1829 it was used by Reid as synonymous with "loss of sensation." The same authority gives the earliest use of the word "anaesthetic" as by J. Y. Simpson in 1847. But five weeks after Morton's famous operation Oliver Wendell Holmes (1847) wrote to Morton to suggest that the state should be called "anaesthesia," from which the adjective would be "anaesthetic." O. W. Holmes appears therefore to be responsible for the birth of the latter word.

Sir James Young Simpson (1871), in quoting from Theocritus, notes that the poet used the word "nodynia" (νόδυνη) for

"insensibility to pain." Simpson stated that he thought this was a better word than "anaesthesia," and that he had often regretted that he had not adopted it. He was therefore probably under the impression even years later that he had been the first to suggest the word "anaesthetic."

Early Attempts to Produce Anaesthesia

Prehistoric Times.—Since there were no written records in prehistoric times, it is natural that our knowledge is entirely speculative. On the analogy of certain primitive races existing in modern times, it has been suggested by some that relief from pain was sought by the agency of magic and witchcraft. The operation of trephination was, however, quite common locally in the neolithic period. It is strange if some degree of anaesthesia was not produced for this operation, either by induced mild concussion or by the use of some drug. A skull of a native of New Ireland in the Wellcome Historical Museum proves that the individual had been successfully trephined eight times during life, and it seems difficult to believe that even a hardy native would have consented to undergo the operation so often unless some anaesthetic had been employed.

The Early Civilizations.—The Assyrians and Egyptians were supposed to use pressure on the carotid arteries to secure temporary loss of consciousness. Prosper Alpinus (1591) stated that the Egyptians used the fumes of Indian hemp to stupefy the patient before operations, but this statement has been contested. The "nepenthe" of Homer (*Odyssey*) was thought by Simpson to have been Indian hemp, and indeed this drug was widely

used as a soporific in ancient times. Pliny mentions it—but not in a medical context. Celsus refers to the use of mandragora, and Spencer considers that he possibly means *Atropa belladonna*. However, it is also admitted that the mandrake may have been indicated.

Of all plants used in the practice of medicine none has a more picturesque history than the mandrake. Still found in the Mediterranean basin, the plant may be said in some ways to resemble a human figure. The ever-recurring legend has it that the plant shrieked when uprooted, and that the uprooter

FIG. 1.—W. T. G. Morton (1819–63).

FIG. 2.—Hickman (1800-1830), the first experimenter in anaesthetics. (From the water-colour painting in the Wellcome Historical Medical Museum.)

fell dead. Hence arose the practice of hitching a dog to the mandrake and letting it suffer extinction. Dioscorides, the famous physician of the first century A.D., wrote much on the mandrake. In the quaint words of his first translator, John Goodyer (Dioscorides, 1934), Dioscorides says: "And some do seeth the roots in wine to thirds, & straining it set it up. Using a Cyathus of it for such as cannot sleep, or are grievously pained, & upon whom being cut, or canterized they wish to make a not-feeling pain." Or, speaking of another sort of mandrake: "For a man sleeps in ye same fashion, as when he ate it, sensible of nothing for 3 or 4 hours, from the time that it is brought to him. And Physitians also, use this, when they are about to cut, or canterize." Randolph studied about 150 passages in Greek and Latin literature which bore on surgery, and he concluded that "the mandragora was the principal and almost the only anaesthetic of antiquity, that the use of anaesthetics never became general." Despite the frequency with which mandragora was mentioned later by lay writers in many countries—compare, for example, *Othello*—it would appear from Oppenheimer's work (1928) that it was not mentioned by any of the Latin poets.

In the second century the Chinese physician Hun T'ao used a wine of unknown composition—*ma-yao*—as an anaesthetic (Sarton).

The Arabian practitioners of the healing art undoubtedly used certain plant infusions as supposed anaesthetics. For example, Avicenna says that if it is desirable to procure a deeply unconscious state so that a painful application to the body can be tolerated, dandelion-water should be given in wine; or fumitory, opium, hyoseyamus, nutmeg, or crude aloe should be administered (Gruner, 1930).

The Middle Ages.—It should be noted that up to this period all the narcotics or would-be anaesthetics which were used were administered by mouth. Before the advent of Salernitan medicine in the Middle Ages, however, a new method makes its appearance—that of the *spongia somnifera*, or soporific sponge—though narcotic beverages, mostly containing mandragora, continued to be used. The earliest known recipe for a soporific sponge is the *Antidotary of Bamberg*, dating from the ninth century. It contains opium, mandragora, cicuta, and hyoseyamus (Sigerist, 1923). The interesting point about these sponges

[10]

taught more suddenly brought on by the agency of sulphuric acid and carbonate of lime. The results in this case were not so satisfactory; some blood escaped from the wounds, and a slight degree of inflammation followed, and the wounds did not heal so rapidly as the first experiment.

EXPERIMENT 4th. Mice, having been confined in a glass tube of a foot long, were rendered insensible by carbonate of soda slowly introduced in small quantities, and one foot from each was taken off; no hemorrhage took place upon the return of sensibility, and the wounds appeared quite healed on the third day, without the animals having apparently suffered pain, when they were given their liberty.

EXPERIMENT 5th. An adult dog was rendered insensible by means similar to the preceding, and the muscles and blood-vessels of one of its legs were divided. There was no hemorrhage from the smaller vessels; a ligature which secured the main artery came away on the fourth day, and the ani-

is that the drugs were haled from the sponge to the nostrils. Baur (18) made a thorough examination of these medicinal recipes, and carried out experimental investigation on animals of the use of various soporific sponges made according to the method. She concluded that the effect produced would be sufficiently marked to warrant their use as anaesthetics in surgery. However, it must be remembered, as she admits, that there was something of the secret; about the surgery of the centuries, and that if a surgeon stumbled on a good narcotic he would tend to keep it to himself.

Later Centuries.—In the sixteenth and seventeenth centuries knowledge of narcotics was largely bound with the trials of witch and the torture of malefactors. It was believed that the swallowing of cer-

types of soap produced narcosis sufficient to dull the pain of torture. Opium was largely used by surgeons, but in 1784 Moreau stated that the strongest dose a surgeon dared give before an operation had little or no effect in mitigating the pain of the procedure. Velpeau, as late as 1832, thought that it was impossible to prevent pain during operations. Alcohol had been employed for centuries, but it was generally admitted that, though success might be achieved by chance in certain cases, there could be no guarantee that this method would be in the least effective.

Mesmerism and Hypnotism

Franz Anton Mesmer (1734-1815) published his book on animal magnetism in 1779, but he was generally derided as a quack and it was not until James Braid became interested in the subject over sixty years later that the possibility of using hypnotic sleep for curative purposes was realized. His book on this subject (1843) was published contemporaneously with the work of the early pioneers of ether anaesthesia. Two entirely different methods of preventing pain during operations were therefore developing at the same time.

Hypnotism was first actually used for this purpose by John Elliotson (1843), of University College Hospital, London. His reaction was so violent that he had to resign from his official posts. Two years later James Esdaile, a Scot resident in Calcutta, found by chance that he had the power to induce in an Indian native a state of hypnosis in which painful stimuli were not felt. He started to use the method for surgical operations, and by 1846—the year in which Morton made ether anaesthesia practicable—Esdaile was able to report 261 painless operations with a mortality of only 5.5%. However, on his return to Scotland Esdaile found the inhabitants of his native country too hard-headed to be susceptible to his influences. Meanwhile "etherization" had started on the path from which it has not since diverged.

Early Pioneers of Inhalation Anaesthesia

The starting-point in the history of inhalation anaesthesia is the fact that Sir Humphry Davy (1800) breathed nitrous oxide in the pure state in 1799. He observed the sensations produced in himself by both low and high concentrations of the gas. He also noted that a headache and the pain associated with the cutting of a wisdom tooth were both relieved at the time of breathing the gas. He suggested that the gas might "probably be used with advantage during surgical operations in which no great effusion of blood takes place." Despite this hint Davy's influence on the development of anaesthesia was only indirect. At the time his suggestion was not followed up, but the practice which he introduced at the Pneumatic Institute at Clifton

inviting visitors to inhale nitrous oxide and note their sensations had important social and medical consequences. Demonstrations of the effects of nitrous oxide were frequently given, and at a later date nitrous oxide parties and "ether frolics" were very popular.

As an example of such a demonstration of the effects of nitrous oxide it is interesting to quote a passage from a little book published in 1839—exactly forty years after Davy had popularized the method. The work is *Chemistry No Mystery* (1839), by John Scoffern, a surgeon and hospital chemist. He professes to report the words of a lecturer who is speaking to a popular audience: "Having proceeded thus far in his Lecture, the old gentleman handed round a great number of bladders filled with the gas (nitrous oxide); and here our shorthand writer ceased from his work. Anxious to enjoy the fun as well as the rest, his office of scribe did not hinder him from seizing a bladder too: for my part I determined to have some amusement of another kind, in witnessing the effects produced by the gas upon others, without breathing any myself; and, perhaps, I laughed more than either of the breathers. Oh, how shall I describe the scene which followed? For one instant, the silence of our Lecture-room was only broken by the deep-drawn inspirations of those who were breathing the gas: all seemed to be enjoying the extreme happiness, they puffed and pulled as if they could not get enough. It was, indeed, irresistibly ridiculous to see a large room filled with persons, each of whom was sucking from a bladder, and this alone made me laugh right well; but in another instant began their ecstasies, some cast their bladders from them with a jerk, and, forgetting the ridiculous figure they made, kept breathing laboriously; their mouths thrown wide open, and their noses still tightly clenched: some jumped over the tables and chairs; some were bent on making speeches; some were very much inclined to fight; and one young gentleman persisted in attempting to kiss the ladies. I have heard it insinuated that he breathed very little of the gas, and that he knew very well what he was doing; but this statement I consider to be untrue. As to the laughing, I think it was chiefly confined to the lookers-on.

"A few minutes served to restore those maniacs to their senses, and they felt as if nothing had occurred; for it is a peculiarity of this gas, that it does not act like intoxicating liquors in producing depression of spirits, disorder of the stomach, or indeed any other unpleasant effects.

"As our instructor had predicted, we did not after this exhibition feel very much inclined to study philosophy, and

FIG. 4.—Crawford W. Long (1815-78).

FIG. 5.—Horace Wells (1815-48).

therefore the Lecture, although short, was brought to a conclusion."

This scene is freely illustrated by George Cruikshank in a frontispiece to the book, which is here reproduced as Fig. 6. An article, attributed to Michael Faraday and pointing out the change of these practices, appeared in the official organ of the Royal Institution (1818). I shall return shortly to the result of one of these strange demonstrations.

Hickman and Suspended Animation

It would be difficult for anyone associated with the Wellcome Historical Museum not to have a tender spot in his heart for Henry Hill Hickman—the Rupert Brooke of anaesthesia—since that Museum possesses practically all his extant manuscripts in addition to a copy of his very rare published work and a number of relics. The Museum also possesses a fine water-colour painting of Hickman carrying out his experiments (Fig. 2). (Owing to an error in the Souvenir Volume (1930) this picture is often wrongly stated to be in oils.) With a view to writing these few lines I have re-studied his writings, which were published in facsimile by the late Sir Henry Wellcome (1930).

Hickman, a "Shropshire Lad," was born in 1800, and before he had attained his majority he had become a member both of the Royal College of Surgeons of London and of the Royal Medical Society of Edinburgh. During his short life of thirty years he practised in Ludlow, in Shifnal, and in Tenbury. Hickman was of a gentle disposition, and he was obviously much affected by the pain which he had to cause while operating. From manuscript notes in this Museum it is proved that his experiments on animals dated from at least the spring of 1823, and on Feb. 21, 1824, he addressed a letter to T. A. Knight, of Downton Castle, near Ludlow, in which he pleads for the use of "suspended animation" in surgical operations, and as an appendix gives details of seven experiments on animals. In the same year Hickman (1824) published an amended version of this letter in pamphlet form, printed by W. Smith of Ironbridge. An important page of this letter is reproduced here (Fig. 3). Knight was a friend of Sir Humphry Davy and a Fellow of the Royal Society—though interested mainly in trees. Hickman obviously hoped that his animal experiments would receive the sympathetic consideration of the great scientists of the day, so that some eminent surgeon might be induced to try his methods on the human subject. His hopes were disappointed. During the next three years he probably continued his experiments, and in 1828 he repaired

FIG. 6.—"Laughing Gas." Cartoon by George Cruikshank, from *Chemistry No Mystery*, by John Scofield, London, 1839.

to Paris, where he addressed a memorial to Charles X. As a result, Hickman's case for a trial of suspended animation was submitted to the Académie de Médecine, which appointed Dubois, Richcrand, Merat, Segallas, and Ribot to constitute a commission and to report. Unfortunately, no evidence has been found of any action taken by the commission. Sick at heart, Hickman returned home, and shortly afterwards died at the age of thirty years:

Hickman believed that suspended animation could be induced without too great risk to life, and in his experimental work he confined animals individually in a bell-jar over water and induced the "torpid state" either by allowing them to rebreathe their own exhaled air or by passing carbon dioxide, produced by the action of sulphuric acid on calcium carbonate, into the bell-jar. While the animal was in the state of torpor he performed a surgical operation on it. In his early experiments he used a puppy, a mouse, a dog, a rabbit, and a kitten. It should be noted that Hickman's object was not only to produce a state in which an operation could be carried out painlessly, but also to ascertain whether the wounds would heal more or less quickly under these conditions. He pointed out that "carbon has a most powerful antiputrescent quality," and believed that a wound made on an animal in a torpid state heals more quickly than one made on a "sensible" animal. It should be noted that in his early experiments Hickman was apparently wedded to carbon dioxide, and that it is only in the memoir of 1828 that the possibility of using other gases is mentioned.

The following appears to me to be a fair estimate of Hickman's importance. (a) In the first place he was one of the earliest, if not the earliest, to carry out planned experiments on animals in connexion with anaesthesia. (b) His adoption of the term "suspended animation" seems to have been fundamental to his system. Insensibility to pain was to be effected by the production of total suspension of most of the functions of animation—the heart being probably the only exception. That he recognized the grave risk is obvious. He said: "I used inflating instruments in one experiment only, and therefore am not prepared to say to what extent such may be used with advantage; but I think it probable that those and the Galvanic fluid would operate in restoring animation in some cases." (c) This being the case, even if Hickman experimented with other gases, which is doubtful, he probably did not conceive of them as acting in such a way that the "state of torpor" was unaccompanied by any serious effect upon a function such

as the respiration. (d) The question arises whether the whole of the effects which were produced in Hickman's experiments were due to asphyxia, or whether any part was a result of the anaesthetic effect of carbon dioxide gas. Chauncey Leake and

FIG. 7.—The ether inhaler designed by Peter Squire and used by him at Liston's operations on Dec. 12, 1846.

Waters (1928) did some work on this problem, and found that carbon dioxide did indeed have in itself a certain anaesthetic effect.

Hickman's position may be summarized finally by saying that he was among the first to carry out planned operations on animals in this connexion, and that he was certainly the first to set out deliberately to obtund the pain of a surgical operation by the inhalation of a gas. In 1847 Dr. Thomas Dudley espoused the cause of his priority, and the resulting correspondence is given in the Wellcome volume.

Founders of Inhalation Anaesthesia

The stage was now set for the men who used effective gases or vapours to produce unconsciousness during surgical operations.

According to Lyman (Keys, 1945) William E. Clarke, a young doctor in Rochester, U.S.A., administered ether on a towel to a Miss Hobbie in January, 1842, and one of her teeth was then extracted painlessly by a dentist, Dr. Elijah Pope. The

FIG. 8.—Sir James Young Simpson (1811-70).

periment arose out of Clarke's knowledge of ether acquired by frequent attendance at "ether frolics." This was apparently the first use of ether for a dental or surgical operation. Clarke did not follow up his discovery, and presumably considered it of no importance.

Crawford W. Long, 1815-78 (Fig. 4), a practitioner of Jefferson, Georgia, had also had experience of "ether frolics," and on March 30, 1842, he used ether, given on a towel, as a general anaesthetic. The patient was a young man called James M. 'enable, and the operation was removal of a tumour on the back of the neck. The operation was successful and painless. During the next four years Long gave ether four or five times. Claims have been made for him as the discoverer of anaesthesia, and statues have been erected in his honour. But Long published nothing at the time, and it was not until 1849 that he issued a statement of the reasons which prevented him from pressing the use of ether by others. None of his reasons is very convincing. In any case, if mere priority of personal use is alone considered, it would appear that Long's claims must now be surrendered in favour of those of Clarke.

Horace Wells, 1815-48 (Fig. 5), was a dentist in Hartford, Connecticut, and on Dec. 10, 1844, he attended a public demonstration of the effects of nitrous oxide, given by "Professor" Colton, a noted lecturer on popular science. As a result of the fact that a friend of Wells who, while under the influence of the gas, did not feel the pain of mild injuries which he had received at that demonstration, Wells determined to try the effect of nitrous oxide for tooth extraction. On Dec. 11, 1844, Wells had one of his own teeth extracted by his colleague, Dr. John M. Rigg, in the presence of Colton, Cooley, and another person. Wells exclaimed afterwards: "I didn't feel it so much as the prick of a pin." Wells was convinced that his discovery was of use to mankind, and determined that it should be made widely known.

After giving nitrous oxide in about fifteen further cases Wells accordingly went to Boston, Mass., where he called on W. T. G. Morton and C. T. Jackson, the well-known geologist and chemist. As a result of his statements John Collins Warren asked Wells to give a demonstration before the class of surgery at the Harvard School. Towards the end of January, 1845, Wells gave this demonstration, but unfortunately the boy whose tooth was being extracted groaned during the operation—although he later stated that he had felt no pain. Wells said later that he had removed the gas-bag too soon. The critical audience laughed and considered the whole thing as a hoax. Wells returned to Hartford and continued to use nitrous oxide and to experiment on certain vapours, but for the world at large surgical anaesthesia remained an unattainable goal—if it was even thought of as a goal at all, except by a few visionaries.

William Thomas Preen Morton, 1819-68 (Fig. 1), a dentist of Boston, had been a pupil of both Wells and Jackson. He had been at the unsuccessful demonstration given by Wells. For some months he appears to have done nothing, although in the subsequent controversies he wrote and said that he had been experimenting on animals and on two assistants with ether

FIG. 11.—Joseph Thomas Clover (1825-82).

during this period. On Sept. 30, 1846, Morton appears to have called on Jackson and asked him to give him some nitrous oxide. Jackson told him his gas-bags were empty and suggested that Morton should try sulphuric ether, which he would find just as efficacious. The same evening Morton used the ether in the extraction of a tooth; the patient was Eben H. Frost. Without delay Morton took his first steps to patent "etherization," and he also called on J. C. Warren and asked permission to give ether as an anaesthetic at the Massachusetts General Hospital. On Oct. 14 Dr. C. F. Heywood, house-surgeon to the hospital, wrote to Morton at Warren's request, inviting him to be present at 10 a.m. on Friday, Oct. 16 (Keys, 1945).

The events which preceded this historic operation, and the operation itself, have often been described (see especially Keys, 1945; Raper, 1945; Duncum, 1946). Morton, in the short time at his disposal, went to considerable trouble to provide himself with a suitable inhaler—a glass globe with two necks. The globe contained "the prepared vapour with sponges to enlarge the evaporating surface." Air entered through the upper neck, and after passing through the vapour, was inspired through the side neck. The side neck or mouthpiece contained a valve which prevented the expired air from passing back into the globe (Bigelow, 1847). This inhaler is still preserved in the Massachusetts General Hospital. The patient was a young printer, Gilbert Abbot (for Abbott); the condition a tumour of the neck; the surgeon, J. C. Warren; and the anaesthetist, W. T. G. Morton. The patient was strapped to an operating chair. The demonstration was completely successful. Warren (1846) published his own account of it. At the end of the operation Warren is reported to have said to the audience: "Gentlemen, this is no humbug." Poor Wells!

On the following day, Oct. 17, Morton gave his second demonstration, in the case of a tumour of the shoulder. This too was successful. In his next case, one of amputation of the breast on Nov. 4, he was unable to anaesthetize the patient after trying for an hour and a half (Raper, 1945). On Nov. 7 he had his most spectacular success. The patient was Alice Mohan and the operation was for amputation of a leg.

The subsequent history of Morton and his discovery is too complicated to be told here. He was a man of affairs, not a scientist. From the first he had been determined to make a fortune out of his method. Even at the Boston operation he

(1813-58)

had added colouring matter and other substances to his liquid ether, and the result he called a "compound." It was not until Nov. 6 that he admitted in a confidential letter to the hospital authorities that his medium was simply sulphuric ether. Almost immediately Morton applied for a patent; but Jackson, who had a reputation for trying to steal inventions, had brought pressure to bear on him, and when the patent was issued on Nov. 12, 1846, it bore the joint names of Jackson and Morton, with Jackson assignor to Morton. A photostat copy of this Letters Patent, No. 4848, lies before me as I write. Morton spent the rest of his life trying to establish his claims, and he made no further contribution to the history of anaesthesia.

First Operation under Ether in Europe

Up to the present it has always been recognized that the first major operation under general anaesthesia in the old world was that carried out by Liston at University College Hospital, London, on Dec. 21, 1846. From research on which I am engaged at the time of writing it is evident that some weeks previous to this date ether was used as a general anaesthetic in a case of amputation of a limb at the Dumfries and Galloway Royal Infirmary. There was a direct link between the Boston operation and that carried out at Dumfries. Scotland can therefore justifiably claim the first use of general anaesthesia in Europe. An extended account of this operation will be published at an early date.*

Practical Application of General Anaesthesia in England

On Nov. 28, 1846, Prof. Jacob Bigelow, of Harvard, wrote to his friend, Dr. Francis Boott, of Gower Street, London, a letter acquainting him of Morton's achievement. Boott was an American, a Harvard man. Bigelow enclosed a newspaper article by his son which related to the discovery. The letter was three weeks in transit, and was probably received by Boott about Dec. 17. On Saturday, Dec. 19, Boott gave ether as an anaesthetic to a Miss Lonsdale while a tooth was extracted by his dentist friend, James Robinson. Meanwhile Boott had written to Robert Liston (Fig. 9) of University College Hospital, and on Monday, Dec. 21, the latter wrote to Boott the historic letter (Liston, 1847) in which he said that he had that day carried out two operations under ether, one being a case of amputation of the thigh, and the other evulsion of both sides of the great toe-nail. Joseph Lister was present at these operations. The anaesthetic was given by Peter Squire, who improvised an inhaler for the occasion (Forbes, 1847) (Fig. 7).

The practice of "etherization" was thus safely launched in this country, and its use on the Continent of Europe followed in the early weeks of 1847.

Simpson and Chloroform

On Jan. 19, 1847, James Young Simpson, of Edinburgh (Fig. 8), was the first to use ether as an anaesthetic in obstetric practice. The ether was given at the time when the labour pains were strongest. Prof. Jacob Bigelow, of Boston, in 1870 claimed that this honour belonged to America, and in his reply Simpson (1871) not only discredited this assertion but gave an illuminating discussion of the whole position. Simpson soon found that his patients objected to the smell of ether, and in an endeavour to discover a more suitable volatile anaesthetic he experimented with various substances on himself and his friends.

The use of chloroform was suggested to him in October, 1847, by David Wallic, Chemist to the Apothecaries' Company of Liverpool. Simpson (1847) began to use chloroform as an anaesthetic in obstetrics early in November, 1847, and he employed it in three cases of operation in the Edinburgh Royal Infirmary on Nov. 15 of that year. Within a matter of weeks it had almost displaced ether as a general anaesthetic.

A word should be said about the heated and prolonged controversy which hinged on religious objections to the use of anaesthetics in childbirth. The objections were on various grounds, but a very strong one depended upon the translation of the Authorized Version of Genesis iii. 16: "In sorrow [etzebb] thou shalt bring forth thy children." Simpson quoted Genesis ii. 21 to show that God was the first Anaesthetist, and he asserted that the Hebrew word 'etzebb' does not imply the sorrow associated with physical pain but rather the muscular effort involved in labour. The controversy did not really abate

until Queen Victoria had chloroform during the birth of Prince Leopold in 1853. It is interesting to note that De Quincey's son, Francis, was a medical student at Edinburgh when chloroform was first used, and he immediately wrote to his father regarding the religious scruples. De Quincey replied, and his arguments against the religious scruples are printed in his collected works (1890). They no doubt helped to get Francis M.D. in 1849.

Snow, Clover, and Late Developments

It is often overlooked that John Snow (Fig. 10), one of the greatest of epidemiologists, was the same John Snow who became the first professional anaesthetist, the first research worker on anaesthetics, and the greatest of all the early workers in the field of practical anaesthetics. A Yorkshireman, Snow was born in 1813, qualified in London in 1838, and by 1841 was working on the scientific aspects of asphyxia. Snow very soon became Liston's anaesthetist, and in November, 1847, he adopted chloroform as a better anaesthetic than ether. Snow devised various types of inhalers and other pieces of apparatus, and the influence of his writings on the later developments of anaesthetic practice was of the greatest importance. He twice gave chloroform to Queen Victoria. Snow was an amateur epidemiologist and he it was who was responsible for terminating the terrible cholera outbreak of 1854, which is known in history as the episode of the Broad Street pump. Snow died in 1858.

Snow's leading place in the anaesthetic field was taken by J. T. Clover (Fig. 11). In 1862 he devised a new inhaler which permitted the accurate regulation of chloroform and air mixtures. This inhaler necessitated the use of a large reservoir by which was slung on the back of the anaesthetist. In 1874 he advocated a supplemental bag which allowed of the rebreathing of a portion of the anaesthetic, and two years later he introduced the gas-ether sequence. In 1877 he devised a portable inhaler for the regulation of the ether flow.

The later developments of the technique of anaesthesia—the controversy over ether versus chloroform, the re-introduction of nitrous oxide in 1862, the Hyderabad Commission, the introduction of new methods, new anaesthetics, and a plethora of new inhalers—are all far too complicated and too recent for warrant discussion here. The trail had been blazed, religious objection had been overcome, and thanks to the greatest of the early anaesthetists the subject had become not only a profession but a science.

Epilogue: The "Discoverer" of Anaesthesia

In this paper I have set out a few of the facts which are known about those who may have some claim to be named the "discoverer" of anaesthesia. On this subject there has been a wealth of writing, not to mention all the arguments which have passed through the United States Courts and Congress over many years. Let each choose according to his judgment. After some considerable study of the evidence I venture to give here my own views.

The five possible contestants are Clarke, Long, Wells, Jackson, and Morton. If by "discovery" we mean a "discovery" to satisfy the discoverer, the palm goes to Clarke by a short head, and then to Long. But Clarke had only one case, which was unpublished. Long had a number of cases over years, but he never expressed the slightest interest in promulgating his discovery. It was apparently only when Farr seemed to be looking for a head on which to bestow the laurels that Long woke up and saw what he had missed. If therefore by "discoverer" we mean one who "uncovers" for the world to see, to use, and to emulate, then both these men are out of the running. Wells is in a different position. He set out consciously to discover an anaesthetic agent which would be effective in major surgery, and he intended that the world should use it. Chance turned him to nitrous oxide. Had not been for the unfortunate circumstances attending his failure and only public demonstration he might have been hailed as the discoverer of general anaesthesia, though not of ether anaesthesia. Jackson, even if he did have the idea that sulphuric ether was the substance to try in the human, took any steps in the matter until jealousy of Morton got him into action. Had Morton not used sulphuric ether, he would have succeeded—at least fairly well—with nitrous oxide. Further, whether or not he had been experimenting with ether

* This operation will be described at a meeting of the History of Medicine Section of the Royal Society of Medicine on Oct. 16.

fore he consulted Jackson, it seems certain that he would be lighted on that substance himself. Discoverers are usually children of preceding events. If one man can be called the discoverer of general anaesthesia, then that man is Morton. On the centenary of his discovery, we salute him for his good fortune, his perseverance, and for the inestimable boon which he conferred on humanity.

On the centenary day, Wednesday, Oct. 16, at 4.30 p.m., an exhibition at the Wellcome Historical Medical Museum, illustrating the whole history of anaesthesia, will be officially opened by Lord Moran.

unpleasantness and tedium of starting with open ether and, on the other, the dangers of a chloroform induction.

Continuous nitrous oxide and oxygen was used to a limited extent with the original Boyle apparatus with bubble sight-feeds, which was based on Gwathmey's American machine. The value of gas and oxygen in shocked battle casualties had been recognized towards the end of the war of 1914-18, and a portable machine designed by Geoffrey Marshall on the same principle as Boyle's apparatus had been used in France. Children were usually given the open ethyl chloride-ether sequence. Inhalation with a face-piece was the predominant technique, although the insufflation endotracheal method had been developed for the plastic repair of facial wounds. For this purpose a stiff gum-elastic catheter was passed into the trachea by direct laryngoscopy. Excision of malignant growths of the tongue and adjacent structures was dealt with by chloroform dropped on to a Hahn cone connected by rubber tubing to a laryngotomy tube. Leakage of blood into the trachea was prevented by a large marine sponge in the oro-pharynx.

Pharyngeal insufflation of chloroform and air from a Junker bottle was used for dissection tonsillectomy and for other operations about the mouth. Occasional alternatives to inhalation were rectal oil-ether and intravenous ether in saline. Local analgesia was practised very considerably, particularly on the Continent. Cocaine was used as a surface analgesic and procaine for injection purposes. These drugs permitted an operating time of only about three-quarters of an hour. Spinal analgesia was confined to hyperbaric solutions, usually of stovaine or tropacocaine, and little was known as to controllability.

Having passed briefly in review the position as it was at the end of the last war, we are now able to assess the advances made in the quarter of a century which has since elapsed.

Preparation of the Patient and Premedication

The preparation of the patient is directed towards putting him in the best possible condition immediately before operation. It may include the administration of extra glucose or possibly a blood transfusion, but there should be an absolute minimum of purging and abstinence from food and drink. Premedication is no longer a mere routine, but is calculated for each individual patient. Sedation is often adequate, usually with a morphine derivative and scopolamine or with an oral barbiturate; but complete basal narcosis may be indicated for the highly strung nervous patient, particularly if suffering from thyrotoxicosis. For this purpose rectal paraldehyde is often used for children and bromethol (avertin) for adults.

If the patient is conscious when he arrives in the anaesthetic room he can then be anaesthetized in a few seconds by an intravenous injection if he dislikes the application of a face-piece. There is no doubt that the introduction of the rapidly acting barbiturates constituted a major advance in anaesthesia between the wars, and although they possess disadvantages (chiefly in producing respiratory depression and a tendency towards laryngeal spasm) they have proved extremely safe in the hands of experienced anaesthetists. For prolonged operations, however, continuous intravenous anaesthesia is not quite so satisfactory as was originally predicted.

New Volatile Anaesthetics

Various new volatile anaesthetics have been introduced since the end of the last war. The hydrocarbon gases were investigated—particularly ethylene, acetylene, propylene, and cyclopropane. Ethylene attained much popularity in America, but never came into extensive use in Great Britain owing to its smell and inflammability. Acetylene had some vogue in Germany. Propylene was found to have too great a tendency to cause cardiac arrhythmias and was soon abandoned. Cyclopropane alone of the series has gained a permanent place in anaesthesia in this country. It possesses the valuable properties of being non-irritating and potent, so that a high proportion of oxygen can be used with it. These properties have encouraged its employment in thoracic surgery in practically all cases in which it is not essential to use the diathermic cautery inside the chest. Owing to its high cost, cyclopropane is always used in a closed circuit.

Certain ethers besides the usual diethyl variety have been investigated, but the only one to attain any popularity has been

RECENT ADVANCES IN ANAESTHESIA

BY

C. LANGTON HEWER, M.B., B.S., D.A.

Senior Anaesthetist and Demonstrator of Anaesthesia,
St. Bartholomew's Hospital

in putting together any account of recent advances the first question to be decided is the meaning to be attached to "recent." The science and art of anaesthesia is now one hundred years old, but it is convenient and also useful to compare the state of the specialty as it was just after the war of 1914-18 with that at the present time.

To deal first with the preparation of the patient: at the beginning of the period selected pre-operative starvation and purging were all too common, and the unhappy victim was often in a very poor condition before the anaesthetic was administered at all. Premedication was practically confined to subcutaneous morphine and atropine administration, basal narcosis being unknown. The anaesthetics in common use were nitrous oxide, chloroform, ether, and ethyl chloride. Short procedures such as dental extractions were usually performed under a "straight" gas, although it must be remembered that Hewitt's two-bag nitrous-oxide-and-oxygen apparatus had been in use since 1892. For minor operations in children the usual anaesthetic was ethyl chloride. For major surgery the two commonest standard techniques were the nitrous oxide-ether-chloroform sequence and nitrous oxide-ether-open ether. In either case anaesthesia was induced with an original or modified Clover's inhaler, thereby obviating, on the one hand, the

divinyl ether. This resembles ethyl chloride, but causes less nausea and vomiting. A tendency towards liver damage necessitates care and the admixture of oxygen for long cases if the drug is used in the pure state; but it can be employed to reinforce diethyl ether in the proportion of 25% ("vinesthene" anaesthetic mixture).

The other new volatile agent which is now in general use is trichlorethylene ("trilene"). This drug has proved extremely useful for producing general analgesia, particularly in midwifery and dentistry, and for the induction and maintenance of a light plane of general anaesthesia (usually with nitrous oxide and oxygen). Trichlorethylene, however, should never be "pushed" to produce relaxation, as tachypnoea is very likely to develop.

Curare in Anaesthetic Practice

At this point curare must be mentioned, as the introduction of this drug into anaesthesia seems likely to mark the greatest advance in recent years. The isolation of the pure alkaloid *d*-tubocurarine chloride by H. King in 1935 has enabled a preparation to be used which is free from undesirable side-actions such as bronchospasm. The main effect of curarine is exerted at the myoneural junction, where it prevents the normal action of acetylcholine from producing muscular contractions; in other words, it is a muscle relaxant, and in normal dosage is neither an anaesthetic nor an analgesic. Curarine has proved extremely useful in upper abdominal surgery, where it is given in divided doses by the intravenous route, the patient being rendered unconscious by very light inhalation or intravenous anaesthesia.

Techniques and Apparatus

Turning now to techniques and apparatus, anaesthetic machines have developed very considerably since the original "Boyle" was introduced in this country. Continuous-flow machines are now provided with accurate dry flowmeters, while the intermittent-flow variety, which will always be associated with the name of the late E. I. McKesson, has proved invaluable where positive pressure is desired, as in continuous nasal gas-and-oxygen for dentistry.

The closed circuit with carbon dioxide absorption by means of a soda-lime canister has resulted in undreamed-of economy in gas consumption and has diminished the risk of explosion when inflammable vapours are being used, besides affording other important advantages to patients. The closed circuit is applicable to most types of inhalation anaesthesia except when paraldehyde has been used for basal narcosis or when trichlorethylene is being employed.

If no gases are available the "Oxford vaporizer" can be used for giving ether and air on the draw-over principle. This is a considerable advance over open ether, as a known percentage of vapour can be used and very fine control is possible. This is accomplished by maintaining the liquid at a constant temperature by means of a chemical thermostat.

The endotracheal technique has changed radically during the period with which we are dealing. The insufflation method with a small catheter is now obsolete and has been replaced by the wide-bore inhalation technique introduced by I. W. Magill. Tight and watertight seal can be provided either by packing or by an inflatable cuff on the tube. It might be mentioned in passing that the introduction of the Davis gag into this country by the late H. E. G. Boyle revolutionized the technique of dissection tonsillectomy, although the original insufflation of anaesthetic vapour through the tube on the tongue depressor is now often replaced by naso-tracheal anaesthesia in adults. This allows a gauze pack to be used, and the surgeon need not inhale any of the anaesthetic vapour through the patient's open mouth.

The "blind" method of nasal intubation, also sponsored by Magill, has proved of great value in many cases. The introduction of tubes into the bronchi and the provision for tracheal and bronchial suction are modifications of the endotracheal technique which the various types of new thoracic operations have necessitated.

The technique of controlled respiration has been developed comparatively recently. In this procedure natural respiration

is abolished, usually by a combination of depressant drugs and hyperventilation with carbon dioxide absorption causing apnoea. Thereafter, intermittent positive-pressure provides for the necessary interchange of gases. The method has proved of very considerable value in thoracic and abdomino-thoracic operations, but it is one which calls for a high degree of skill in use.

New Drugs and Methods in Local Analgesia

Local analgesic techniques have advanced to cover a great variety of field and nerve blocks, perhaps the most popular now being brachial plexus block. It would appear, however, that for abdominal surgery local analgesia will largely be replaced by the combination of intravenous curare with very light general anaesthesia.

The usual syringe employed is still Labat's original pattern although various types of self-filling syringes are used for extensive infiltrations. The pressure infiltrator has been developed to a high degree of perfection, but its weight and bulk have prevented its general adoption.

Very many new drugs have been tried as local analgesics but, apart from the original cocaine and procaine, nupercaine and amethocaine alone have attained any real popularity in Great Britain. Both have a good surface action and a prolonged effect. A modern tendency is to use infiltration, not to produce analgesia, but to aid the surgeon by separating tissue planes and by causing ischaemia. For this purpose a 1:500,000 adrenalline solution in normal saline is excellent.

The refrigeration of limbs has proved useful for amputation in patients in very poor condition. It should be noted that the tissues are not frozen in the same way as when using an ethyl chloride spray, but are simply cooled to about 5°C.

Spinal analgesia has undergone many changes. The introduction of nupercaine has enabled a truly hypobaric solution to be used for the first time, and this has some advantages for high blocks. The mechanism of distribution of injectable drugs is now more fully understood, and this has enabled blocks which are mainly unilateral to be achieved. Probably less use is made of spinal analgesia than formerly, however, owing to the large number of serious complications that have been recorded, some of which appear to be unavoidable even with a theoretically perfect technique. It seems likely that curare will replace high spinal blocks to a large extent in the future. Extradural spinal block has become rather more popular since it was shown that with the spine flexed there is normally negative pressure in the extradural space. The use of the "hanging-drop" technique or a special indicator has resulted in the positioning of the needle being less problematical.

Care of the Patient's General Condition

The care of the patient's general condition during operation is one of the duties of the anaesthetist, and in this connexion fresh progress has been made in the determination of blood pressure such as the use of the sphygmoscope devised by Evans and Mendelssohn. If restorative measures are necessary the anaesthetist must be prepared to set up an intravenous drip of saline, plasma, or blood, while sudden collapse may make the administration of an analeptic advisable. A very large number of these drugs have been introduced since 1918, two of the most popular and reliable being nikethamide and methedrine.

The advance of anaesthesia has been assisted by the adoption of better records than had previously been available. In this country the combined blood-pressure/pulse chart and record card, adapted to an extremely ingenious card index system by M. D. Nosworthy, is making possible the comparison of different techniques from the study of many thousands of cases.

In conclusion, it must not be forgotten that the skill of the man behind the rifle is more important than the design of the weapon or the type of ammunition used; in other words, the ability of the individual anaesthetist is more important than new introductions of drugs or techniques. More than ever before must the anaesthetist possess the knowledge and skill to select and use the best method for anaesthetizing any particular patient for any given operation.

THEORIES OF ANAESTHETIC ACTION

BY

J. H. BURN AND H. G. EPSTEIN

*(From the Department of Pharmacology and the Nuffield
Department of Anaesthetics, Oxford)*

This vast subject has been studied by so many that it is impossible to do more than indicate briefly a few of the most important observations and the theories based upon them. But it is always safe to begin with Claude Bernard (1875), who defined narcosis as a depression of the activity of lower forms of life which disappeared when the substance causing the depression was removed; he thus distinguished a narcotic from a substance producing an irreversible change. The depression might be a depression of motility, a loss of irritability, a cessation of mitosis, or a slowing of metabolic processes. Anaesthesia is a term first proposed by Oliver Wendell Holmes in a letter to Morton in 1846; it is used when narcotics are given to a more highly developed organism such as man. The essential feature remains that the depression, the loss of consciousness, and other effects must be reversible.

The stages of anaesthesia are marks of a progressive depression beginning in the cortex and proceeding lower. The cortex itself is affected at certain points more than at others, for the sensory area is depressed when the motor cortex is still active; when finally the depression has travelled to the spinal cord there is muscular relaxation. The fortunate exception to this progressive paralysis is the medulla, in which the respiratory and vasomotor centres still function when the musculature is relaxed, so far as most anaesthetics are concerned. But this is not true of all. If attempts are made to obtain muscular relaxation with nitrous oxide the respiratory centre fails owing to oxygen lack first. With cyclopropane, again, the margin between muscular relaxation and respiratory failure is narrow. The differences in the sensitiveness of various parts of the brain are, however, small compared with the difference between the sensitiveness of the brain and that of other tissues.

Sensitivity of the Brain to Anaesthetics

During the time taken by operations, anaesthetics accumulate in the brain more than in other tissues such as muscle, and the greater sensitiveness of the brain is thus accompanied by a greater affinity for anaesthetics. It was at one time thought that the accumulation of an anaesthetic in the brain was due to the greater blood supply of that organ; after long-continued anaesthesia, however, some accumulation is observed at a time when the differences due to blood supply must have disappeared (Nicloux and Yovanovitch, 1924). The greater affinity of brain tissue for anaesthetics may have its explanation in the tissue composition. So long ago as 1847 von Bibra and Harless based their theory of narcosis on the high lipid content of the brain, which they suggested was dissolved out of that organ by the anaesthetic and deposited in the liver! Fifty years later the well-known theory of Meyer (1899) and Overton (1899, 1901) was also based on the high lipid content of the brain.

A third difference between the brain and other tissues is its great susceptibility to the effects of oxygen lack: there are indeed very great differences between brain and other nervous tissue. Thus the small pyramidal cell area of the cerebrum and the Purkinje cell area of the cerebellum, when deprived of oxygen, die in about 10 minutes. On the other hand, the spinal cord survives for 50 minutes and the sympathetic ganglia for 200 minutes. An explanation for the great sensitiveness of the brain to anaesthetics would therefore be provided if it could be shown that anaesthetics interfere with processes of oxidation, as some have suggested. Such evidence would also account for the steps in which the different portions of the central nervous system are influenced by the narcotic agent. Owing to the differences in the sensitiveness of the different parts of the central nervous system, workers since Claude Bernard have in the main studied the action of narcotics in lower organisms. Even among these Meyer and Overton found that a small increase in the extent of organization and functional differentiation was accompanied by an increased sensitiveness to narcotics.

Primary Action of Narcotics

Two very obvious features of narcotics are the great variation in their chemical structure and that most of them enter and leave the tissues unchanged; these facts suggest that the primary action of narcotics cannot be chemical, but must rather be due to the production of physical changes such as in solubility, adsorption, etc. Among the many changes which narcotics have been said to produce, those about which there is a balance of agreement are a decrease in the permeability of the cell to water and water-soluble substances, and also a diminution in the state of hydration. Lucké (1932), for example, observed that in the unfertilized egg of the sea-urchin water exchange through the surface is reduced by narcotics. Anselmino (1928), too, has confirmed earlier observations that narcotics delay the haemolysis of red cells by hypotonic solutions, and that the length of the delay is in linear proportion to the concentration of the narcotic. Gerstner (1940) has shown that the permeability of the skin covering the frog's abdomen for ions is diminished in the presence of various alcohols. Turning to evidence for a diminution in the state of hydration, we find that Lapique (1930) observed in nervous tissue that, in a concentration which reduces conduction, narcotics cause dehydration. Kochmann (1923a) observed a similar effect in frog muscle immersed in 0.75% saline: when the narcotic was applied the weight of the muscle diminished; when the narcotic was removed the weight returned to its former value.

TABLE I.—(Kochmann, 1923a)

	Chloroform	Chloral Hydrate	Ether	Ethyl Alcohol
Molar concentration	0.004	0.006	0.19	1.0
Weight loss %	2	10	2.5	5.0

The figures in Table I show the wide variation between the concentrations of different narcotics necessary to produce a certain degree of anaesthesia. They also show that, in narcosis, dehydration occurs and the percentage loss of weight in the tissue is not correlated with the concentration of the narcotic in the surrounding fluid; the weight loss therefore cannot be due to osmosis, which is in any case unlikely, since the narcotic enters the cell. Actual water loss is observed when medium concentrations of chloral hydrate act on fibrin flakes (Jurisic, 1937). Heilbrunn (1920) observed that the cytoplasm of sea-urchin eggs becomes more fluid under the influence of narcotics, indicating that water is set free.

Narcotics not only produce dehydration in living cells but exert effects on colloidal solutions which can also be interpreted as dehydration. Labes (1921) observed that alcohols affected albumin solutions so that they were more easily precipitated by other agents, and the effect increased with the number of carbon atoms in the alcohol used. Now since the stability of hydrophilic (water-attracting) protein colloids depends on the degree of hydration, it seems very likely that the effect of the alcohols was to produce dehydration. It is worth noting that Claude Bernard, and later Bancroft and Richter (1931), have based their "coagulation" theory of narcosis on the reduction of the stability of colloids and their precipitation. Unfortunately for their theory there are substances which reduce this stability but have no narcotic action; the experimental evidence supporting this theory is still meagre.

In all these experiments it is important to note that the changes were reversible provided that the concentrations of the narcotics used were not excessive. Moreover, the effect of any one narcotic was in linear relation to its concentration in all experiments in which different concentrations were studied.

While narcotics produce narcosis when applied in most concentrations, in very low concentrations they appear to cause excitation. Even in anaesthesia of human subjects there may be an element of actual excitation, though the usual explanation which is given of the stage of excitement is that it is due to the release of lower centres from the control of higher centres, the real effect of the anaesthetic being to depress these higher centres. If narcosis is actually due to diminished permeability, and if the early stage of excitation is considered to be the opposite, it should be accompanied by increased

permeability. Gerstner found such an increase in the frog's skin, and then, after the application of higher concentrations, the permeability was diminished. Lapicque also observed that with low concentrations of narcotics there was an increase in nerve conduction and also an increase in hydration. Beecher (1938) quotes several observations showing that very low concentrations of narcotics always increase the normal functions of small organisms. These effects of low concentrations, however, have not been very extensively studied, and relatively little is known about them. Nevertheless, since they occur, any theory of narcosis which is to be satisfactory must explain them.

Before discussing a theory which considers dehydration as the primary effect of a narcotic, it should be pointed out that the process is not merely a withdrawal of water such as occurs in osmosis. The withdrawal of water by osmosis causes no change in the force of attraction between a "hydrophilic" colloid and water, whereas the dehydration we are now considering involves a diminution of this attraction (Seelich, 1941). It is therefore evident that only certain kinds of water withdrawal will have a narcotic effect. A further point is that the dehydration and the decreased permeability due to narcotics are not independent. In experiments with artificial membranes it has been found that dehydration leads to diminished permeability (Gurewitsch, 1934).

The Dehydration Theory

Traube (1904, 1935) introduced a theory of narcosis which was later greatly extended by Lillie (1909) and Warburg (1920). This theory depended on the parallelism between the potency of a narcotic and the degree to which the narcotic reduced the "surface energy" of a water-air boundary.

The surface energy of pure water is measured by the work which must be done to enlarge the surface by 1 sq. cm. The molecules inside are held there by the attraction of other molecules, and in order to move molecules to the surface this attraction must be overcome. The surface energy of water is much greater than that of organic fluids like oil. Small amounts of certain substances dissolved in water (or other liquids) diminish its surface energy, and their activity is measured by the reduction in surface energy which a given concentration produces. Owing to the force of attraction which they exert being less than the force exerted by water molecules, these substances are less attracted to the interior, and therefore displace water from the surface. These substances are termed "surface-active." If an attempt is made to increase the surface the molecules of the substance will require less work to put them there, so that the surface energy is reduced. Accumulation of a substance in a surface, or adsorption, is inseparable from a reduction in surface energy. If we consider a water-oil boundary, the interface energy is less than that of a water-air boundary, because the oil molecules exert an attraction on water molecules in the interface which the air does not, and thereby reduce the pull from the bulk of the water. Certain substances which dissolve in oil lower this interface energy still further; they do this by a similar process to that just described at a water-air boundary, and they accumulate in the interface.

If we come to an interface between protein colloids or lipids and water, their attraction for water is usually so strong that the interface energy is very small. These colloids are said to be "strongly hydrated." If we add to such a system a third substance which would cause great reduction of surface energy at a water-air boundary it will have very little effect, because the surface energy is already so low. The slight reduction which might be caused by adding a "surface-active" substance would, however, lead to increase in hydration of the protein or lipid.

If now we consider narcotics, some of which are strongly surface-active at a water-air boundary, we know from the experimental observations discussed that at medium concentrations they do not cause hydration, but on the contrary dehydration. This fact excludes any hypothesis of their action which involves adsorption on the cell membrane surface as the primary mechanism. Simple models of cell membranes can be made, however, in which surface-active narcotics cause dehydration and an increase in surface energy. The basis for these models is the idea that the lipid content of a cell mem-

brane is a mixture, some components being strongly surface-active or hydrophilic, and accumulating (that is to say, being adsorbed) on the surface. Other components, being the greater part of cell-membrane lipids, are less hydrophilic. Seelich (1940) suggests that the narcotics dissolve in the lipids of the cell membrane and thereby alter the distribution of the surface-active lipids between the surface and the interior of the membrane; the surface-active lipids come inside, and their place is taken on the surface by less hydrophilic lipids. Dehydration therefore occurs, the interface energy rises, and permeability diminishes.

One of the models chosen by Seelich consists of a layer of liquid paraffin in contact with water. This system has an interface energy of 51. The surface-active lipid component represented by 0.05% ergosterol in the liquid paraffin. This reduces the water/paraffin interface energy to 4—a value in the same order as that of the interface energy between lipid and water. When a strong surface-active narcotic, *n*-propyl alcohol, is added in a concentration of 0.3 mol/litre, the interface energy does not decrease, but rises from 4 to 8. We know that the narcotic effect of homologous alcohols rises with the number of carbon atoms in the chain, and when the above experiment is done with butyl alcohol the same rise of interface energy is obtained with only 0.05 mol/litre. If so much ergosterol is put in the paraffin that some of it is undissolved and present as visible droplets, it can be observed that the addition of narcotics to the water results in the solution of these droplets in the paraffin. It is of further interest that for very low narcotic concentrations—e.g., 0.01 mol/litre propyl alcohol—a decrease of interface energy, indicating increased hydration and permeability, occurs in the model; this bears out what has been observed in actual cells.

Other Theories of Narcosis

We can now consider how far other theories of narcosis can be harmonized with this. Traube correlated narcotic activity with lowering of the surface energy of a water-air boundary, such a boundary constitutes a bad model for the cell membrane plasma boundary, and, as already pointed out, lowering of surface energy is accompanied by hydration, not by the dehydration which actually occurs.

Warburg has extended Traube's rules to form a comprehensive theory. Like Traube, he assumes an accumulation of narcotics on the surface of cell membranes; this is supposed to lead to a displacement of enzymes from positions on the surface in which they catalyse oxidations; at the same time the adsorption of narcotics is supposed to "block the pores" of the membrane, leading to a decrease of permeability. Some of the evidence for this theory is that amino-acids, adsorbed on activated charcoal, are displaced when narcotics are added. It is unlikely that the water-repellent surface of charcoal is a good model for the water-attracting colloids of the cell membrane. Moreover, the arguments valid against Traube's theory apply here also.

The earlier theory of Meyer and Overton is really a rule and not a theory, since it does not explain narcotic action. It points out that there is a close relation between narcotic activity and the distribution coefficient of narcotics in a lipid/water system. (If oil is in contact with water and a narcotic is added, the narcotic distributes itself in a fixed ratio between the oil and the water. This ratio is the distribution coefficient.) The coefficient rises as the narcotic increasingly prefers the oil. The son of Hans Horst Meyer—namely, K. H. Meyer (1937)—has recently re-examined the distribution coefficients and has used oleic alcohol instead of the classical olive oil to represent the lipid phase. He compared the distribution coefficients with the concentrations of narcotics in water necessary to paralyse tadpoles. The figures he got are given in the first two columns of Table II, and it can be seen that the narcotizing concentration for tadpoles diminishes as the distribution coefficient rises. In the last column is given the concentration which would have been present in oleic alcohol in contact with water containing the narcotizing concentration in the first column. The figures in the last column are very close together, and Meyer concludes that to obtain narcosis the same concentration of any narcotic in certain lipids is required.

TABLE II

	Narcotic Conc. for Tadpoles (mol/litre H ₂ O)	Distribution Coefficient Oleic Alcohol-Water	Narcotic Conc. mol/litre of Lipoid Model
yl alcohol ..	0.33	0.10	0.033
yl alcohol ..	0.11	0.35	0.038
yl alcohol ..	0.03	0.65	0.020
et ..	0.024	2.10	0.050
ninal ..	0.008	5.90	0.048
loroform ..	0.00008	325.00	0.026

The Meyer-Overton theory appears to fit easily into the framework of the dehydration theories of Kochmann (1923b) and Seelich (1940). A high distribution coefficient means that when there is a low concentration of the narcotic in the water there is enough narcotic in the lipid to alter the distribution of the surface-active lipid components, with consequent hydration and decreased permeability. Warburg's conception of the displacement of enzymes may also be useful, even if the sorption of the narcotics on membrane surfaces is rejected. The surface-active lipids which are displaced may indeed be enzymes, and their removal may be responsible for the diminished oxidation which is observed (Quastel and Wheatley, 1934). The decrease in permeability may hamper the transport of carbohydrate to the enzymes, and so reduce metabolism in another way. Since, too, the transmission of stimuli is accompanied by the passage of ions through the cell membrane, the reduction of permeability (Winterstein, 1926; Hoeber, 1926) will interfere with this transmission, and cells will become unresponsive.

In conclusion, certain modern electrical theories of narcosis could also be mentioned which are based on the idea that the anisotropic state of negativity arising when a nerve is stimulated is interfered with by narcotics. It is thought that a narcotic first produces a state of negativity on the cell surface as does a normal stimulus; the subsequent paralysing effect is seen in the persistence of the negative state, which would have disappeared immediately after a normal stimulus. No further stimuli which normally cause a state of negativity to travel along a nerve can now be transmitted, since the cell membranes are maintained in maximum negativity by the action of the narcotic (Beutner, 1931). These theories infer the stages of excitement and paralysis to be of the same kind, while the experimental evidence discussed above seems to point to a difference between the two; moreover they do not attempt to provide evidence that the electrical state of the narcotized cells is correlated with the potency of narcotics in a homologous series. Until this has been done their value is uncertain.

JOHN SNOW—ANAESTHETIST AND
EPIDEMIOLOGIST

In the senior common room of a college mention of the name Poincaré would ring a bell, or rather it would ring bells. The modern historians would suppose the French Premier and President in question: the mathematicians that his cousin was intended. In medical circles the name Snow excites memories not of two men but of the different activities of one man. Probably in a mixed company more would remember Raymond Poincaré the statesman than Henri Poincaré the mathematician: certainly in a medical company more would recollect Snow as the English pioneer of scientific anaesthesia than as an epidemiologist. But Snow's classical papers on the epidemiology of cholera have been reprinted in America with an excellent introduction.¹

John Snow (1813-58), the son of a Yorkshire farmer, was educated for general medical practice and, as an apprentice, had experience of the 1831-2 epidemic of cholera in Newcastle. He "walked" the Westminster Hospital in 1837-8, qualified in 1838, and graduated M.B.Lond. in 1843, M.D. 1844. His first paper, "Asphyxia and the Resuscitation of New-born Children," was published in 1841. In 1846 the first inhalations of ether in this country did not greatly impress surgeons. "The distrust arose," wrote Benjamin Ward Richardson, "from the manner in which the agent was administered." Snow remedied the mistakes and soon became known as an anaesthetist. He published a short treatise on ether anaesthesia in 1847. After the introduction into medical practice of chloroform by Simpson, Snow carried out a number of researches and satisfied himself of the practical advantages of the drug. He soon became one of the most successful and respected anaesthetists in London.

The cholera epidemic of 1848 perhaps recalled memories of his experience in general practice, and he published a brochure of 31 pages "On the Mode of Communication of Cholera" in 1849. The second edition (139 pages) published in 1854 is a classic of epidemiology. Snow's incrimination of a pump in Broad Street, Golden Square, is as dramatic as any detective story, but the statistical evidence by means of which he established a high correlation between the consumption of dirty water and mortality from cholera in South London is a model of research. Private enterprise and free competition in the sale of water had the result that in one and the same street families might buy water from different companies. Snow was supplied by the General Register Office with the names and addresses of persons dying of cholera in the epidemic of 1854; he and another medical man made a house-to-house visitation, and from the data the collection of which "was necessarily attended with a good deal of trouble," he was able to draw up an unanswerable case against dirty water. William Farr, who gave him every encouragement, was able to produce in the epidemic of 1866 equally cogent statistical evidence. Where Snow was in advance even of Farr and Simon was in his firm conviction that the ingestion of water polluted with a presumably living contagium was the only method of epidemic dissemination. Farr to some extent, and Simon to a greater extent, still hankered after that variant of miasmatic epidemiology which found a possible cause of epidemics in air contaminated by the products of putrefaction.

English science has owed much to amateurs, and it may be that Snow will be longer remembered by his researches in epidemiology—undertaken because the subject interested him—than by his professional work, valuable as that was.

¹ *Snow on Cholera . . . with an Introduction by Wade Hampton Frost*. New York: The Commonwealth Fund, 1936.

The Bristol Council for Rehabilitation was inaugurated on Oct. 4, 1945, at a meeting attended by members of the Bristol and District Divisional Hospitals Council, and representatives of the Ministries of Health, Labour and National Service, hospitals, medical institutions, and industry. Its constitution is modelled on that of the British Council for Rehabilitation, with which it is affiliated. A report of the first year's work has been issued from Royal London House, Queen Charlotte Street, Bristol, 1.

THE HISTORY AND DEVELOPMENT OF ANAESTHETIC APPARATUS

BY

A. CHARLES KING, F.I.B.S.T.

Perhaps the first modern gas inhaler was the one which James Watt, renowned engineer, constructed for Humphry Davy in 1799; this was a gasometer to which was attached an almost impermeable silken bag from which he inhaled the gas. It is probable that William Allen, lecturer on chemistry, used this at Guy's Hospital in 1800 when, before Astley Cooper and others, he demonstrated the results of inhalation of nitrous oxide, noting especially the loss of sensation of pain.

ment. It must be wider than the trachea, to compensate for a resistance arising from friction of the air against the interior of the tube. It is therefore $\frac{3}{4}$ in. (1.9 cm.) in internal diameter. The pipe for the admission of air to the ether is but $\frac{5}{8}$ in. (1.6 cm.) in diameter, but that is amply sufficient, since it has to give passage to a much smaller volume of fluid than the elastic tube; for the air expands to nearly twice its bulk, in passing over the ether, the vapour it takes up.

"The method of obliging a person to get all the air he breathes through tubes and valves, which is essential to success in the inhalation of ether, is perfectly new, and, in such a process, greater facilities for respiration are required than would generally have been supposed. On this account, many of the apparatuses at first invented did not allow of easy respiration, but offered obstructions to it by sponges, by the ether itself, by valves of insufficient size, but more particularly by tubes of too narrow calibre; and there is reason to believe that, in many instances, this was the cause

1799.—Humphry Davy's nitrous oxide gasometer.

1847.—Snow's ether apparatus.

1853.—Snow's portable chloroform inhaler.

1862.—Clover's chloroform bag.

1860.—Colton's nitrous oxide machine.

1846.—Morton's ether inhaler.

1867.—Junker's inhaler.

In 1846 William T. G. Morton demonstrated the practicability of ether anaesthesia in an operation performed by Dr. J. C. Warren in the Massachusetts General Hospital, Boston. His inhaler was perhaps the first piece of apparatus proper, in so far as it had a definite tube for the patient to inhale from. In England the first administration of ether took place in the house of Dr. Boott, 24, Gower Street, London, close to the University College Hospital, on Dec. 19, 1846. Two days later Robert Liston performed an amputation through the thigh, the patient being anaesthetized by Mr. Peter Squire. John Snow, the first physician-anaesthetist, began administering ether at St. George's Hospital, and in his book, published in 1847, describes an apparatus he had used for three months. It may not be generally realized how profound were many of Snow's views, as this quotation from his book on ether will show:

"The breathing-tube ought to be so capacious as to offer no impediment to the most rapid inspiration; and to meet this require-

ment, failure and that in others the insensibility, when produced, was partly due to asphyxia."

In 1853 Snow successfully administered chloroform to Her Majesty Queen Victoria at the birth of Prince Leopold, most probably using his portable inhaler, which was made of metal and consisted of a double cylinder, the outer space of which contained cold water, the inner serving for the evaporation of the chloroform. This inner frame had numerous openings for the admission of air; two coils of stout bibulous paper absorbed the chloroform. Slots were cut in this paper to permit of an air passage, only sufficient chloroform being poured into the container as would leave a clear passage. This period cannot be passed without mention of the fact that in 1858 Snow used endotracheal apparatus on animals.

In 1862 Clover put into practice Snow's principle of a measured quantity of chloroform in a bag of known capacity which he suspended from his shoulders. This contained

efficient air and vapour for several administrations. The face-piece incorporated valves to allow the patient to inspire air or a mixture of air and chloroform, together with a simple expiratory valve.

The original Junker's inhaler was described in the *Medical Times and Gazette* of Nov. 30, 1867. Junker may have attended an exhibition of obstetric and other instruments held in London the previous year where Richardson's anaesthetic spray was exhibited, and in consequence conceived the idea.

members of the Odontological Society and the Dental Hospital of London. The report was generally in favour of the anaesthetic, but noted the bulkiness of the apparatus required. At this time nitrous oxide was generally made by the dentist in his own surgery and was heated in a retort, the issuing gases passing through a series of wash-bottles, where some impurities were removed, thence to a gas-holder, when it would be ready for administration to the patient. A suggestion that nitrous oxide be compressed into liquid form was made in the *British*

1876.—Clover's gas-ether apparatus.

1871.—Trendelenburg's endo-tracheal tube.

1877.—Clover's ether inhaler.

1909.—Guedel's gas-air apparatus.

1892.—Hewitt's gas-oxygen apparatus.

1912.—Kelly's intratracheal tube.

1903.—Vernon Harcourt's chloroform-regulator.

1910.—McKesson's intermittent flow gas-and-oxygen apparatus.

In 1867 C. Q. Colton, who had popularized the use of nitrous oxide, visited Paris and demonstrated before T. W. Evans, an English dentist practising there. Evans came to England in 1868, bringing with him a record of hundreds of cases. He gave a demonstration at the Dental Hospital, using as an apparatus a bladder or rubber bag with the patient rebreathing through a tube of large calibre held in the mouth. The success of this and other demonstrations was so great that a committee of investigation into nitrous oxide was formed composed of

Medical Journal, and Messrs. Coxeter and Messrs. Barth made cylinders devised by T. W. Evans; these were of copper and were brass-bound, but were bulky. Cylinders measuring approximately 10 by 6 in. (25 by 15 cm.) held only about 30 gallons at from 10 to 15 atmospheres (present cylinders of 100 gallons capacity measure 13 by 3½ in. (33 by 9 cm.)).

In July, 1876, Clover described in the *British Medical Journal* his apparatus for administering nitrous oxide gas and ether, singly or combined, and at the time of writing had used his

apparatus successfully in 2,000 cases. The gas supply from a cylinder led through a water-heated coil traversing a rubber tube within the large gas-bag to the inhaler, the apparatus being so arranged that gas could be given alone or with air, or, if ether were needed, a tap could be turned, causing the gas to enter the receiver containing ether, pass over the surface of the ether and thence to the facepiece. The amount of gas or ether was regulated by the tap on top of the receiver, whilst the amount of air was regulated by the valve near the facepiece. In January, 1877, Clover described in the *British Medical Journal* his "portable regulating inhaler." Many modifications were made in subsequent years, the most important being the enlargement of the inner bore first suggested by Wilson-Smith and carried into practice by Hewitt. In 1892 Hewitt introduced the first practical nitrous-oxide-and-oxygen apparatus, of which the principle was to maintain by foot-key control equal pressures of nitrous oxide and oxygen, whilst hand manipulation of a regulating stopcock and mixing chamber governed the amount of oxygen added to the nitrous oxide administered.

In 1898 Alfred Coleman, H. J. Paterson, and Harvey Hilliard all described different methods of nasal gas inhalation. Coleman's was the one that was brought to the notice of the Society of Anaesthetists. It was Harvey Hilliard who suggested the use of nasal tubes, his plan consisting of introducing a catheter through the nostril so that its free end hung over the opening in the larynx. In 1899 the S. S. White Dental Manufacturing Company produced the first American gas-oxygen apparatus following the plan devised by Hewitt. Vernon Harcourt, in 1903, produced a chloroform-regulating apparatus for measuring accurately the strength of chloroform in air. Two indicating gravity beads, floating at different levels, enabled the operator to regulate the temperature to between 13 and 15° C. The stopcock was so made that when the pointer was at the end of the arc nearest the chloroform the maximum quantity being administered was 2%. The first gas-air apparatus was devised in 1909 by Arthur E. Guedel.

This was misnamed a self-administering apparatus as it was not automatically controlled, for the bag could be kept inflated by constant adjustment of the cylinder key.

In 1910 McKesson perfected the first "intermittent" flow gas-and-oxygen apparatus, with an accurate percentage control, and in 1911 he introduced the principle of fractional rebreathing. In 1926 the fractional rebreathing bag was arranged under the ether vaporizer, but by 1930 the whole apparatus had become more compact; the supply bags were reduced and enclosed in metal drums, whilst the rebreathing bag was fitted at the rear of the apparatus. The Walton apparatus was designed in 1925, the gas and oxygen bags being fitted with automatic cut-off controls and an accurate mixing valve. The present-day model embodies all the features of the original, but is improved mechanically and encased in metal.

In 1910 Boothby and Cotton introduced their water-sight-fee'd apparatus, which was later modified by Gwathmey. Boyle brought one to England in 1916, and the following year saw the introduction of the portable Boyle apparatus. A chloroform bottle was added in 1920, and in 1926 by-pass controls,

on Clover's principle, were incorporated. Four years later the plunger device was designed for the better control of anaesthetic vapour. Dry flowmeters were adopted in 1931, and in 1937 the rotameter pattern superseded these.

Endotracheal Apparatus

Snow, in 1858, described a wide-bore tube which he inserted into the trachea of an animal, respirations passing in and out of a bag filled with chloroform vapour. It was not, however, until 1871 that Trendelenburg used this method in man; he performed preliminary tracheotomy and inserted a wide-bore tube carrying an inflatable cuff connected to a funnel covered with gauze, maintaining anaesthesia by chloroform drop. Kuhn, at the turn of the century, eliminated the need for tracheotomy by designing a flexible metal tube that was introduced orally.

The forerunner of all modern endotracheal apparatus was designed in 1912 by Kelly, who adopted the principles laid down by Elsborg two years earlier. Kelly confirmed that warm moist air, charged with definite proportions of ether vapour, could be blown through a gum-elastic catheter reaching down to within an inch (2.5 cm.) of the bifurcation of the trachea. Magill, Rowbotham, Hower, and Shipway, in the early 'twenties, developed the method and produced their individual apparatuses.

Carbon Dioxide Absorption

The idea of the carbon dioxide technique had entered the fertile brain of John Snow, but it was not until 1915 that the first apparatus was made by Dennis Jackson, who, though he did not have the opportunity of trying out his experiments on man, suggested that human patients could be anaesthetized by his methods. His early experimental work was successfully demonstrated, clinically, by Ralph Waters in 1920. Waters' apparatus consists of a rubber face-mask and breathing-bag, connected by a metal canister containing soda-lime, and is capable of being used with any standard gas apparatus.

Several years later, Sword, Heidbrink, and Foregger made circuits of the "circle" type as opposed to the Waters "to-and-fro" canister, as some anaesthetists preferred a minimum amount of apparatus near the field of operation. In 1932 the first apparatus proper in this country was made for Frankis Evans, and this was followed by alternatives designed by Shipway, Harris, Halton, Primrose, Gillies, and others. The most compact apparatus devised in recent years is that suggested by Gillies in 1938, wherein use is made of wide-bore perforated tubes to overcome the disadvantage of the moisture of the patient's expirations tending to waterlog the wick of the ether vaporizer. The Coxeter-Mushin absorber was introduced in 1941, its main features being a two-way soda-lime circuit, a wickless ether vaporizer, and an arrangement for assisting respirations manually.

Analgesic Apparatus

Minnitt's intermittent apparatus was designed in 1933 for the self-administration of gas and air in midwifery. The apparatus was entirely automatic, allowing a maximum of 45% gas with

1915.—Dennis Jackson's CO₂ absorber.

1925 (circa).—Waters' soda-lime canister.

1917.—Boyle's portable apparatus.

to flow only as and when the patient inhaled. Other models allowed, but the principle remains the same to-day.

The Mennell bottle, designed in 1933 for chloroform anaesthesia, utilized principles that were later adopted by Freedman for the self-administration of trichlorethylene. Where Mennell used hand bellows as the motive power, Freedman, by enlarging the bore, used the patient's inhalations for the same purpose.

This précis of my lecture on the development of anaesthetic apparatus cannot be concluded without paying tribute to the work of the pioneers of old. To them is owing a great debt for many of the mechanical principles that have been followed in the last twenty-five years—a period during which greater advances have been made than in the previous seventy-five years.

ANAESTHESIA THROUGH THE EYES OF A POET

BY

GUNILLA LIDDLE

The thick, sweet mystery of chloroform" has been the subject of scientific papers and of popular histories of anaesthesia, but it is not so generally known that a poet has made chloroform its theme. Just thirty years after the discovery of the anaesthetic properties of chloroform William Ernest Henley recorded, in what at that time was a bold experiment in verse, his sensations when chloroform was administered. To the literary historian *Hospital Verses* is of considerable interest for Henley's complete break with the subject matter and forms of Victorian poetry: to the doctor in this centenary year of the discovery of anaesthesia *Hospital Verses* has a certain historical significance as well.

William Ernest Henley (1849–1903) was the son of an erratic Gloucester printer. He went to the Crypt School in Gloucester, where the head master in Henley's day was T. E. Brown, the minor poet. From the time when he was a schoolboy or even earlier there is evidence that Henley had some form of tuberculous infection, and it was always despite ill health that he carried on his work as a journalist. As well as producing a great deal of original work Henley held several editorial appointments and gathered round him always the most brilliant of the writers of the day. This article, however, is concerned only with the years 1873–75, which Henley spent in the Old Infirmary, Edinburgh, where he was attended by Lister.

Before Henley came under Lister's care the doctors had tried all the remedies then in favour. One horrible treatment is described by Henley's youngest brother, Joseph, who went with him to the butcher's slaughter-house in search of a cure. "We both went next day. I was very sad, but he hopped along plithe and gay on his two crutches. . . . He and I both went into the slaughter-house, and saw a poor beast not long down and the butcher at work cutting open its inside. I was a bit scared, but my brother sat down on an old bench and I removed the covering from his bad foot. Then I saw the butcher drag a great mass from the beast's interior and pull it across the stone floor to where my brother was sitting, make a large slit in it with his big knife, and into this my brother put his bad foot, keeping it there for ever such a time."

Such treatment was unsuccessful, however, and the foot had to be amputated. For a time this sufficed, but when Henley was 24 the doctors decided that the other foot must come off too. It was at this point that Henley rebelled and determined to seek the help of Lister, then becoming known for his use of antiseptics in surgery. So Henley set out alone for Edinburgh, arriving at the Old Infirmary on Midsummer Day, 1873.

"The morning mists still haunt the stony street;
The northern summer air is shrill and cold;
And lo, the Hospital, gray, quiet, old,
Where Life and Death like friendly chaffers meet.

.....

"A tragic meanness seems so to environ
These corridors and stairs of stone and iron,
Cold, naked, clean—half-workhouse and half-jail."

Thus Henley describes his coming to a "gruesome world" which was to be his for twenty months. As he lay and waited for the "Chief" to operate he knew that now at least he had the consolation of chloroform. "Before" describes the hours of taut anticipation.

"Behold me waiting—waiting for the knife.
A little while, and at a leap I storm
The thick, sweet mystery of chloroform,
The drunken dark, the little death-in-life."

This poem and the three that follow—"Operation," "After," and "Vigil"—form a sequence describing in disturbingly new verse patterns and with a grim but completely sure choice of epithet the mental and physical phantasmagoria of the hours before and after Lister operated. Here is "Operation."

"You are carried in a basket,
Like a carcass from the shambles,
To the theatre, a cockpit
Where they stretch you on a table.

"Then they bid you close your eyelids,
And they mask you with a napkin,
And the anaesthetic reaches
Hot and subtle through your heing.

"And you gasp and reel and shudder
In a rushing, swaying rapture,
While the voices at your elbow
Fade—receding—fainter—farther.

"Lights about you shower and tumble,
And your blood seems crystallizing—
Edged and vibrant, yet within you
Racked and hurried back and forward.

"Then the lights grow fast and furious,
And you hear a noise of waters,
And you wrestle, blind and dizzy,
In an agony of effort,

"Till a sudden lull accepts you,
And you sound an utter darkness . . .
And awaken . . . with a struggle . . .
On a hushed, attentive audience."

The half-world between consciousness and unconsciousness is described in "After," when his life appeared to Henley as a flickering flame round which the fumes of anaesthetic swirl.

"Like as a flamelit blanketed in smoke,
So through the anaesthetic shows my life;
So flashes and so fades my thought, at strife
With the strong stupor that I heave and choke
And sicken at, it is so foully sweet.
Faces look strange from space—and disappear.
Far voices, sudden loud, offend my ear—
And hush as sudden. Then my senses fleet . . ."

In the months that followed, Henley, lying in that "transformed back kitchen" with a home-made desk fixed to his bed, learnt languages and read and recorded the scenes and people who filled his hospital world. Lister, the most important person in that world, is portrayed as "The Chief."

"His brow spreads large and placid, and his eye
Is deep and bright, with steady looks that still
Soft lines of tranquil thought his face fulfill—
His face at once benign and proud and shy.
If envy scout, if ignorance deny,
His faultless patience, his unyielding will,
Beautiful gentleness and splendid skill,
Innumerable gratiitudes reply.
His wise, rare smile is sweet with certainties,
And seems in all his patients to compel
Such love and faith as failure cannot quell.
We hold him for another Herakles,
Battling with custom, prejudice, disease,
As once the son of Zeus with Death and Hell."

And Lister on his rounds: the students much the same, the rites of approach unchanged. The familiar scene—only really seen by the patient—is sketched by Henley in rapid, angular verse unsmoothed by rhyme, in "Clinical."

"Husles the Class! And they ring themselves
Round the first bed, where the Chief
(His dressers and clerks at attention),
Bends in inspection already.

PROVINCIAL MEDICAL & SURGICAL
JOURNAL, 1847

We reprint below three articles of interest in the early days of anaesthesia which appeared in the *cursor* of the BRITISH MEDICAL JOURNAL. The account of amputation under ether anaesthesia is the first reference in the PROVINCIAL MEDICAL & SURGICAL JOURNAL to the new discovery. The leading article is of interest because of the use of the short-lived words "letheon" and "letheon". J. Y. Simpson's account of the use of chloroform as an anaesthetic was first given in a lecture and subsequently published at about the same time in LANCET, the LONDON MEDICAL GAZETTE, and the PROVINCIAL MEDICAL & SURGICAL JOURNAL—in the issue of Dec. 1 of the last periodical. The case of amputation of the thigh was published in the issue of Jan. 13.

CASE OF AMPUTATION OF THE THIGH UNDER THE INFLUENCE OF ÆTHER

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

As the medical profession at this moment must feel interested in the late discovery, made by our Transatlantic friends, of the inhalation of æther producing that state of narcotism which renders persons insensible to the pain of surgical operations, I offer no apology for sending you the following brief account of an experiment as to its efficacy which came under my own observation yesterday. My patient, Mr. Coleman, having occasion to perform amputation of the thigh upon a young woman of a highly nervous temperament and who dreaded the pain of the operation exceedingly, deemed it a favourable opportunity to test the efficacy of the new discovery. By the kind assistance of Mr. Julion, a talented young chemist, we prepared the necessary apparatus for conducting the experiment. The patient being brought to the edge of the bed, the tourniquet applied, and everything prepared to commence amputation, she began to inhale the æther, which produced a good deal of coughing, and it was with some difficulty we prevailed upon her to persevere, which she at length did not, however, in a very satisfactory manner, drawing only slight inspirations, and then removing the tube from her mouth. After using it for the space of three or four minutes, her teeth became fixed, her eyes closed, and she sank back into the arms of the attendant, as if in a state of complete intoxication. Mr. Coleman now seized this favourable moment, and very adroitly and expeditiously performed the flap operation. The patient struggled with her hands, and cried out for her mother, (who had been dead some years.) The sound limb was not held, nor did she move it, but frequently said "she would not have her leg cut off then;" indeed it was quite evident she was not aware of the operation being performed; for after the stump was dressed, and she was comfortably placed in bed, she said "I was not off, for her foot was asleep," and begged of some one to rub it. On enquiring of her, some hours after the operation, what she had felt, she said "she thought she had been in a dream, and that we had hurt her leg, to see if she could bear the operation, which was to be performed the next day." She had no recollection of any cutting pain, nor could she tell the kind of pain she had suffered, but thought she remembered "hearing the bone sawed."

The narcotic effect of the æther soon subsided; for in putting in some sutures to bring the edges of the stump together, the passing of the needle through the skin, produced cries of the most agonizing pain, though her mind was not sufficiently restored to consciousness, to be aware of what was going on.

The result of this trial I cannot but think highly encouraging, and fully believe, that if the inhalation had been more per-

So shows the ring
Seen from behind round a conjuror
Doing his pitch in the street.
High shoulders, low shoulders, broad shoulders, narrow ones,
Round, square and angular, serry and shove;
While from within a voice,
Gravely and weightily fluent,
Sounds; and then ceases; and suddenly
(Look at the stress of the shoulders!)
Out of a quiver of silence,
Over the hiss of the spray,
Comes a low cry, and the sound
Of breath quick intaken through teeth
Clenched in resolve. And the Master
Breaks from the crowd, and goes . . ."

This is the rhythm of pain and of tragedy, but a different rhythm—a jiggy little tune—is chosen in "Interlude" for an eerie ballet danced to a penny whistle when

"Kate the scrubber (forty summers,
Stout and sportive) treads a measure . . .

Of their mattress-life oblivious,
All the patients, brisk and cheerful,
Are encouraging the dancer,
And applauding the musician.

Dim the gas-lights in the output
Of so many ardent smokers,
Full of shadows lurch the corners . . ."

The daily pattern of mood is blacker and whiter in hospital than in the outside world, but in *Hospital Verses* there is little complaint save in the bitter, hopeless last lines of "Pastoral." Henley glimpses spring through his hospital window, and

"A sprightliness feeble and squalid
Wakes in the ward, and I sicken,
Impotent, winter at heart."

Despair passes, and in "Music" Henley reveals one of those moments in which peace is made more peaceful by the heightened sensibility of illness. So at the sound of a distant barrel organ "piping foolish ditties"

"Books, beds, bottles, floor, and ceiling
Fade and vanish,
And I'm well once more . . .

O the sight and scent,
Wistful eye and perfumed pavement;
In the distance pipes an organ . . .
The sensation

Comes to me anew
And my spirit for a moment
Thro the music breathes the blessed
Airs of London."

It is interesting to see how in this nostalgic mood Henley returns to the echoes of older verse forms and to the evocative diction and rhythms so markedly different from the rest of *Hospital Verses*.

At last in 1875 Henley was discharged from the Old Infirmary, and for every man in every time he cried:

"Carry me out
Into the wind and sunshine,
Into the beautiful world . . .

These are the streets;
Each is an avenue leading
Whither I will.

Free . . .
Dizzy, hysterical, faint,
I sit, and the carriage rolls on
Into the wonderful world."

[Acknowledgment: *Poems*, by W. E. Henley (Macmillan)]

Two bottles of agar, supplied by the Southern Group Laboratory of the London County Council to the War Office late in 1940 or early in 1941, were found in Singapore when it was recaptured last year. They had formed part of the equipment of an advanced medical stores depot in Malaya and had been captured by the Japanese forces in 1942. They were found on examination to be in perfect condition—a good testimonial to the efficacy of the bottled media system.

fectly accomplished, the state of insensibility would have been most complete. So satisfied am I, that we now possess a means of narcotizing pain, that I shall not hesitate to adopt it in any case where a painful surgical operation has to be undergone, taking care in future to render my patient thoroughly conversant with the mechanical process of inhalation, previously to the use of the æther.

I remain, Sir,

Your obedient servant,

GEORGE EDWARDS.

Wolverhampton, Jan. 2, 1847.

P.S. January 3rd. Our patient is going on very favourably, and still persists she had a dream during the operation.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, MARCH 10, 1847.

The process of inhaling æther for the avoidance of pain during surgical operations, has taken so fast hold of almost every professional man in this country, that it behoves the journalist to look to the subject, and from his focus of information scatter a few useful remarks and cautions on the employment of this new process.

How often has accusation been made by enthusiasts of various descriptions against members of our profession generally, for their incredulity and prejudices in respect to the several delusions with which this age of quackery teems. Yet was censure never less justly applied. The profession are commonly eager enough to embrace any new proposal, and give a laudatory report of its application; too often indeed, at first, without due regard to its effects, or rather perhaps its defects, whenever there is reason and probability in its favour. In the instance of this novel plan for diminishing human suffering, whatever may have been stated on other occasions, sufficient has occurred to redeem the character of the profession, and to prove the readiness of its members to adopt any new suggestion, when supported by facts, and by the slightest colouring of reason.

Whatever hints may previously have been given upon this new application of æthereal inhalation, we are undoubtedly indebted to our Transatlantic brethren for effectively starting it in practice, "*Palmas qui meruit ferat*." Not he who tamely offers a suggestion, but he who with energy and spirit forces his ideas upon the public, and starts them into practical life and activity, deserves the credit of an invention. In the short space of a few weeks the æthereal inhalation has been tried in our own country in many hundreds of instances; in all parts of the provinces, as well as in the great centres, the metropolis of each division of the kingdom; employed for avoiding pain, not only in the slighter matter of teeth-extraction, but in all cases of the great amputations and other capital operations, and even to strangulated hernia, extirpation of the eyes, ovariectomy, the Cæsarean section, &c.

In a small proportion only of these cases, of whatever description, has the process failed to take effect; and although to a few patients it has proved inconvenient, to none is it reported to have proved fatal, and very little has yet been written upon the cases to which the new measure is inapplicable. Such is the usual course of a novel plan launched upon the wide ocean of practice under popular favour. All appears fair for a prosperous voyage; but it is a voyage of discovery; the quick-sands and dangers are at a distance, and we must wait the navigator's return ere we can learn the whole issue of the undertaking.

The inhaling for the production of narcotic or intoxicating effects is not new, but the extensive adoption of it, in the manner we are considering, may still render a new term convenient, and even necessary. The instrument employed, of whatever construction, has received the appellation of "the Lethæon," and from this root is readily to be derived all the terms required. The phenomena which a *lethæonized* patient

presents, are very similar to those of intoxication, varying in degree from hilarity to half consciousness, complete narcotism, total insensibility to external impressions, failure of pulse, syncope,—may we not add death.* The most striking, if not the peculiar circumstance, is the rapidity with which the effect is produced, the shortness of its duration, and its equally rapid subsidence. The brain is the organ acted upon, and in proportion as external impressions are shut out, internal ideas seem to be generated. A *lethæonized* patient is a sort of Ryp Van Winkle; he dreams away twenty years of his past life in a minute, but with equal surprise, and unlike his predecessor, on awaking to the world again, finds it much as he left it. These psychological phenomena will doubtless furnish a fine study for the physiologist and the metaphysician.

Nothing is more remarkable than what every one who sees half-a-dozen *lethæonized* patients will be sure to witness,—a state of half-consciousness, with eyelids open, a congested countenance, a frightened stare. The patient is sensible of persons present, and talking, and because he is still in a degree sensible, protests against the operation, whilst it is actually being performed; and on the *lethæonic* influence subsiding, which it does in two or three minutes, he reports the trial a failure, and waits the operation, which is already completed without his being conscious of it. How are such opposite states of the sensorium compatible? May we conjecture that the succession of ideas is so rapid, that they seem coincident or synchronous, though really successive and alternating?

But we pass to the less speculative part of the subject, as more immediately applicable to our purpose, and we urge our provincial brethren to emulate those of the metropolis in helping to elucidate the use of the Lethæon, and particularly to giving us an account of any unfavourable result of the trial,—any cases that may seem unsuited to it. We can scarcely persuade ourselves that the pain naturally attendant upon all mutilating operations upon the human frame, is to be quite annihilated by this discovery, although nothing could be more congenial to the wishes of both the patient and the operator. It will probably turn out that there are cases to which the measure is wholly unsuited, wholly improper. When next "we dip pen" in æthereal fluid, we shall endeavour to write a few cautions, and give a guarded prognosis, as to past or prospective events; meantime, let the incautious Lethæonizer beware, remembering that "all is not gold that glitters."

DISCOVERY OF A NEW ANÆSTHETIC AGENT MORE EFFICIENT THAN SULPHURIC ÆTHER

By J. Y. SIMPSON, M.D.,

Professor of Midwifery in the University of Edinburgh,
Physician Accoucheur to Her Majesty in Scotland, &c.

At the first Winter Meeting of the Medico-Chirurgical Society of Edinburgh, held on the 10th of November last, I had an opportunity of directing the attention of the members to a new agent which I had been using for some time previously, for the purpose of producing insensibility to pain in surgical and obstetric practice.

This new anæsthetic agent is chloroform, chloroformyle, or perchloride of formyle.† Its composition is expressed by the chemical formula, C_2HCl_3 . It can be procured by various processes, as by making milk of lime or an aqueous solution of caustic alkali act upon chloral; by distilling alcohol, pyroxylic spirit, or acetone with chloride of lime; by leading a stream of chlorine gas into a solution of caustic potash in spirit of wine, &c. The resulting chloroform obtained by these processes is

* Since the preceding observations were written, a notice of the occurrence of a fatal case, which will be found narrated in another column, has been received.

† In making a variety of experiments upon the inhalation of different volatile chemical liquids, I have, in addition to perchloride of formyle, breathed chloride of hydrocarbon, acetone, nitric oxide of ethyle, benzine, the vapour of iodoform, &c. I may probably take another opportunity of describing the results. It is perhaps worthy of remark, that in performing his experiments upon inhalation, Sir Humphry Davy confined his attention to the inspiration of gasses, and does not seem to have breathed the vapour of any volatile liquids.

a heavy, clear, transparent liquid, with a specific gravity as high as 1.480. It is not inflammable. It evaporates readily and boils at 141°. It possesses an agreeable, fragrant, fruit-like odour, and a saccharine pleasant taste.

As an inhaled anæsthetic agent it possesses, I believe, all the advantages of sulphuric æther, without its principal disadvantages:—

1. A greatly less quantity of chloroform than of æther is requisite to produce the anæsthetic effect; usually from a hundred to a hundred and twenty drops of chloroform only, being sufficient, and with some patients much less. I have seen a strong person rendered completely insensible by six or seven inspirations of thirty drops only of the liquid.

2. Its action is much more rapid and complete, and generally more persistent. I have almost always seen from ten to twenty inspirations suffice; sometimes fewer. Hence the time of the surgeon is saved; and that preliminary stage of excitement, which pertains to all narcotizing agents, being curtailed or indeed practically abolished, the patient has not the same degree of tendency to exhilaration and talking.

3. Most of those who know from previous experience the sensations produced by æther-inhalation, and who have subsequently breathed the chloroform, have strongly declared the inhalation and influence of chloroform to be far more agreeable and pleasant than those of æther.

4. I believe that, considering the small quantity requisite, as compared with æther, the use of chloroform will be less expensive than that of æther, more especially as there is every prospect that the means of forming it may be simplified and cheapened.

5. Its perfume is not unpleasant, but the reverse; and the odour of it does not remain for any length of time obstinately attached to the clothes of the attendant, or exhaling in a disagreeable form from the lungs of the patient, as so generally happens with sulphuric æther.

6. Being required in much less quantity, it is much more portable and transmissible than sulphuric æther.

7. No special kind of inhaler or instrument is necessary for its exhibition. A little of the liquid diffused upon the interior of a hollow-shaped sponge, or a pocket handkerchief, or a piece of linen or paper, and held over the mouth and nostrils, so as to be fully inhaled, generally suffices in about a minute or two to produce the desired effect.

I have had an opportunity of exhibiting chloroform with perfect success in various severe surgical operations, (removal of tumours, of necrosed bone, amputations, &c., &c.) and in tooth-drawing,* opening abscesses, &c., &c.; for annulling the pain of dysmenorrhœa and of neuralgia; in two or three cases where I was using deep and otherwise very painful galvanopuncture for the treatment of ovarian dropsy; and in removing a very large fibrous tumour from the posterior wall of the uterus by enucleation, &c.†

I have employed it also in obstetric practice with entire success. The lady to whom it was first exhibited during parturition, had been previously delivered in the country by perforation of the head of the infant, after a labour of three days' duration. In this, her second confinement, pains supervened a fortnight before the full time. Three hours and a half

* A young dentist, who has himself had two teeth extracted lately, one under the influence of æther, and the other under the influence of chloroform, writes me the following statement of the results:—"About six months ago I had an upper molar tooth extracted whilst under the influence of æther, by Mr. Imlach. The inhalation was continued for several minutes before I presented the usual appearance of complete ætherization. The tooth was then extracted; and although I did not feel the least pain, yet I was conscious of the operation being performed, and was quite aware when the crash took place. Some days ago I required another molar extracted on account of tooth-ache, and this operation was again performed by the same gentleman. I inhaled the vapour of chloroform, half a drachm being poured upon a handkerchief for that purpose, and held to my nose and mouth. Insensibility took place in a few seconds; but I was so completely dead this time, that I was not in the very slightest degree aware of anything that took place; the subsequent stupefying effects of the chloroform went off more rapidly than those of the æther; and I was perfectly well and able again for my work in a few minutes."

† I have now exhibited the chloroform to a large number of individuals, and in not one has the slightest bad effect of any kind resulted

after they commenced, and ere the dilatation of the os uteri was completed, I placed her under the influence of the chloroform, by moistening, with half a teaspoonful of the liquid, a pocket-handkerchief, rolled up into a funnel-shape, and with the broad or open end of the funnel placed over her mouth and nostrils. In consequence of the evaporation of the fluid, it was once more renewed in about ten or twelve minutes. The child was expelled in about twenty-five minutes after the inhalation was begun; the mother subsequently remained longer soporose than commonly happens after æther. The squalling of the child did not, as usual, rouse her, and some minutes elapsed after the placenta was expelled, and after the child was removed by the nurse into another room, before the patient awoke. She then turned round and observed to me that she had "enjoyed a very comfortable sleep, and indeed required it, as she was so tired,* but would now be more able for the work before her." I evaded entering into conversation with her, believing, as I do, that the most complete possible quietude forms one of the principal secrets for the successful employment of either æther or chloroform. In a little time she again remarked that she was afraid her "sleep had stopped the pains." Shortly afterwards her infant was brought in by the nurse from the adjoining room, and it was a matter of no small difficulty to convince the astonished mother that the labour was entirely over, and that the child presented to her was really her "own living baby."

Perhaps I may be excused from adding, that since publishing on the subject of æther-inhalation in midwifery, seven or eight months ago,† and then for the first time directing the attention of the medical profession to its great use and importance in natural and morbid parturition, I have employed it, with few and rare exceptions, in every case of labour that I have attended and with the most delightful results, and I have no doubt whatever that some years hence the practice will be general. Obstetricians may oppose it, but I believe our patients themselves will force the use of it upon the profession.‡ I have never had the pleasure of watching over a series of better and more rapid recoveries, nor once witnessed any disagreeable result follow to either mother or child, whilst I have now seen an immense amount of maternal pain and agony saved by its employment; and I most conscientiously believe, that the proud mission of the physician is distinctly twofold—namely, to alleviate human suffering, as well as preserve human life.

In some remarks which I published in the *Monthly Journal of Medical Science*, for September, 1847, relative to the conditions for insuring successful ætherization in surgery, I took occasion to insist upon the three following leading points:—"First, the patient ought to be left, as far as possible, in a state of absolute quietude and freedom from mental excitement, both during the induction of ætherization and during his recovery from it. All talking and all questioning should be strictly prohibited. In this way any tendency to excitement is eschewed, and the proper effect of the æther-inhalation more speedily and certainly induced. Secondly, with the same view, the primary stage of exhilaration should be entirely avoided, or at least reduced to the shortest possible limit, by impregnating the respired air as fully with the æther-vapour as the patient can bear, and by allowing it to pass into the lungs both by the mouth and nostrils, so as rapidly and at once to induce its complete and anæsthetic effect, * * * a very common but certainly a very unpardonable error being to exhibit an imperfect and exciting, instead of a perfect and narcotizing, dose of the vapour. Many of the alleged failures and misadventures are doubtless entirely attributable to the neglect of this simple rule,—not the principle of ætherization, but the mode of putting it in practice being altogether to blame. But, thirdly, whatever means or mode of ætherization is adopted, the most important of the conditions required for procuring a satisfactory and successful result from its employment in surgery, consists in

* In consequence of extreme anxiety at the unfortunate result of her previous confinement, she had slept little or none for one or two nights preceding the commencement of her present accouchement."

† See "*Monthly Journal of Medical Science*," for Febr., p. 617, for March, p. 718, and 721, &c.

‡ I am told that the London physicians, with two or three exceptions only, have never yet employed æther-inhalation in midwifery practice. Three weeks ago I was informed in a letter from Professor Montgomery, of Dublin, that he believed that in that city up to that date, it had not been used in a single case of labour.

ostinately determining to avoid the commencement of the operation itself, and never venturing to apply the knife until the patient is under the full influence of the æther-vapour, and *roughly and indubitably soporized by it.*"

In fulfilling all these indications, the employment of chloroform evidently offers great and decided advantages in rapidity, facility, and efficiency over the employment of æther. When used for surgical purposes, I would advise it to be given upon a handkerchief, gathered up into a cup-like form in the hand of the exhibitor, and the open end of the cup placed over the nose and mouth of the patient; for the first inspiration or two should be held at the distance of half an inch or so from the face, and then more and more closely applied to it. To insure a full and perfect anæsthetic effect,—more especially when the operation is to be severe,—a teaspoonful or two of the chloroform should at once be placed upon the hollow of the handkerchief, and immediately held to the face of the patient. Generally a state of snoring sleep very speedily supervenes, and when it does so, it is a perfect test of the superinduction of complete insensibility. But many patients are perfectly anæsthetic without this symptom.

As illustrations of the influence of this new anæsthetic agent, I will select and append notes of two operations performed with it on Friday last by Professor Miller, the first in the Royal Infirmary,* the other in private practice. The notes and remarks are in Mr. Miller's own words.

CASE I.

"A boy, four or five years old, with necrosis of one of the bones of the fore-arm. Could speak nothing but Gaelic. No means, consequently, of explaining to him what he was required to do. On holding a handkerchief, on which some chloroform had been sprinkled, to his face, he became frightened, and wrestled to be away. He was held gently, however, by Dr. Simpson, and obliged to inhale. After a few inspirations he ceased to cry or move, and fell into a sound snoring sleep. A deep incision was now made down to the diseased bone; and, by the use of the forceps, nearly the whole of the radius, in the state of sequestrum, was extracted. During this operation, and the subsequent examination of the wound by the finger, not the slightest evidence of the suffering of pain was given. He till slept on soundly, and was carried back to his ward in that state. Half an hour afterwards he was found in bed, like a child newly awakened from a refreshing sleep, with a clear merry eye, and placid expression of countenance, wholly unlike what is found to obtain after ordinary etherization. On being questioned by a Gaelic interpreter, (who was found among the students,) he stated that he had never felt any pain, and that he felt none now. On being shown his wounded arm, he looked much surprised, but neither cried nor otherwise expressed the slightest alarm."

CASE II.

"A young lady wished to have a tumour (encysted,) dissected out from beneath the angle of the jaw. The chloroform was used in small quantity, sprinkled upon a common operation sponge. In considerably less than a minute she was sound asleep, sitting easily in a chair, with her eyes shut, and with her ordinary expression of countenance. The tumour was extirpated, and a stitch inserted, without any pain having been either shown or felt. Her sensations, throughout, as she subsequently stated, had been of the most pleasing nature; and her manageableness during the operation was as perfect as if she had been a wax doll or a lay figure.

"No sickness, vomiting, headache, salivation, uneasiness of chest, in either of the cases. Once or twice a tickling cough took place in the first breathings."

My assistant, Dr. Duncan, who exhibited the chloroform to this last patient, informs me that about a drachm of the liquid was used.

Edinburgh, November 15, 1847.

* Professor Dumas, of Paris, Mr. Milne Edwards, Dr. Christison, Sir George Ballingall, and a large collection of professional gentlemen and students witnessed this operation, and two others performed with similar success, by Professor Miller and Dr. Duncan.

Medical Memoranda

Insanity with Epilepsy following Infestation by *Cysticercus cellulosae*

In the case of insanity with epilepsy associated with cysticercosis reported below, the patient demonstrated the fact that this type of epilepsy carries with it the concomitants of the ordinary idiopathic type—i.e., mental deterioration, as shown by the intelligence test. The aura depends on the site of the cyst in the brain, and focal symptoms are also present. The prognosis in this case is unfavourable.

CASE REPORT

A man aged 32 was admitted to the Central Hospital, near Warwick, on Dec. 11, 1944, as a certified patient. He had entered the hospital some five months earlier, but as a voluntary patient. On this occasion he was suffering from an amnesia for recent events; and could not give a full account of himself. He had suffered from convulsive attacks and had been operated on before admission; there were two trephine holes in his occipital bone. Since this operation he noticed that the onset of the fits was different from what it had been before, but he could not tell the difference. His intelligence, estimated by the Terman Merrill revision of the Stanford-Binet test, gave an I.Q. of 83, a vocabulary age of 274 months, and a mental age without vocabulary age of 128 months, showing a loss of 53%. He made an uneventful recovery, having had only two major fits, and left hospital against advice after 14 days, only to return certified in December, 1944.

On readmission he was violent, aggressive, confused, threatening, and untidy. He quickly settled down, and on the following day he was apologetic, friendly, and co-operative. He showed appropriate activity during examination and answered questions put to him sensibly but slowly. There was some evidence of memory defect. He expressed no delusions or hallucinations, and he was not suicidal. Later he was dull, apathetic, and in a state of confusion, answering questions slowly and irrelevantly. He had contracted cysticercosis while in the Army, and for the last six years had been subject to attacks of fits, followed on many occasions by threats of violence by knife or other weapons, especially after taking alcohol. His actions were irresponsible and his mental condition showed degeneration.

History.—One day, while serving with the Army in India in 1936-7, he ate wild bear which had been shot in a hunt. Two days later he noticed elements of worms in his stools. He reported this, and was treated in hospital; more elements came away with the head. Later he developed difficulty in passing water and had to be catheterized frequently, his urine being blood-stained. After 12 weeks he was discharged from hospital as fit for duty. He left India for home on leave, and while on the boat felt a strange sensation of tension in his right arm, and then lost consciousness. This unpleasant sensation repeated itself several times at home, and in 1943 an operation was performed on his brain, following which the sensation of tension in his right arm disappeared. During his fits he sustained two major injuries—a bad laceration over his right eyebrow, and a serious concussion following a bicycle accident.

Clinical Picture.—He was a well-built man 6 ft. 3 in. (1.9 m.) in height, weighing 11 st. 3 lb. (71.21 kg.). His blood pressure was 120/75; the heart sounds were faint but regular. The respiratory system showed nothing abnormal. He had glycosuria, which cleared up in a week. There was some asymmetry of his mouth, with weakness of the left lower lip, and weakness of the left buccinator muscle, demonstrated by filling his cheek with air. This was associated with a partial closure of the left eye. His tongue deviated slightly to the right on protrusion. There was some dulling to pin-prick over the left side of his face. Reflexes in his upper limbs were diminished, with no impairment of sensation, joint sense, or power. There was some diminution of sensation on the left lower limb, with an absent plantar reflex. The pupils were equal, and reacted to light and accommodation; blurred vision in left eye. Ophthalmoscopic examination revealed a honeycomb type of choroiditis at both macular regions, more pronounced in the left eye. There was no evidence of cysticercosis in the fundi or media. Blood picture showed no gross abnormality except an eosinophilia of 1%. There was no evidence of worm elements in the faeces. Skiagrams revealed two areas of calcification in the skull, one in the right axilla, and three in the left thigh. Since readmission the patient has had only one *grand mal* attack; this was controlled by 1 gr. (65 mg.) of luminal twice daily.

Mental State.—He was childish, dull, simple, and irritable, and he suffered from violent outbursts of temper, particularly following alcohol (before admission). He showed pronounced memory deterioration and had ability for stereotyped work only.

I thank Dr. Edward S. Stern, medical superintendent, Central Hospital, for helpful criticism and for permission to publish this case, also Miss E. A. Estell, psychologist, and Mr. Howell-Jones, visiting ophthalmic surgeon, for special examinations.

EDWARD B. FORSTER, M.B., Ch.B., B.A.O.,
Late Temporary Assistant Medical Officer.

Central Hospital, near Warwick.

Reviews

GYNAECOLOGICAL ENDOCRINOLOGY

Gynaecological Endocrinology for the Practitioner. By P. M. F. Bishop, D.M. (Pp. 124. 7s. 6d., plus 3d. postage.) Edinburgh: E. and S. Livingstone. 1946.

In his introduction to *Gynaecological Endocrinology for the Practitioner*, Dr. Bishop says that he set out to write "a short book which will explain as far as possible the mechanism of the various disorders of endocrine activity occurring in their women patients; a book which will tell them [general practitioners] which hormones to use in treatment, when, how, and in what doses; a book which will try to dispel the chaos which has been created in their minds by the predilection of pharmaceutical business houses to give proprietary names to endocrine preparations." This statement adequately describes the scope of this work and it only remains to be added that Dr. Bishop has been singularly successful in achieving his objects. Here is a simple, up-to-date, and accurate account of the physiology of menstruation with an explanation of the cause and treatment of the common disorders of menstruation, puberty, climacteric, conception, and pregnancy; this and more, all within the compass of 81 pages of text. There are no conflicting views and references, but clear and reasonably dogmatic statements based on a fair assessment of the evidence at present available and on the experience of an acknowledged authority in this field. An important contribution to the practical value of this book is a 30-page appendix listing the proprietary products marketed in this country, the form in which they are available, their hormone content, and current price.

Dr. Bishop says he is not aware of any other book on this subject written primarily for general practitioners. We know of others, but none so good. It is scientifically sound and eminently practical, easy to read and to understand. It should prove most useful to the busy practitioner and to the final-year medical student.

GASTRO-ENTEROLOGY

Gastro-Enterology. By Henry L. Bockus, M.D. Volume I—The Esophagus and the Stomach. Volume II—The Small and Large Intestine and Peritoneum. Volume III—The Liver, Biliary Tract and Pancreas, and Secondary Gastro-Intestinal Disorders. With General Index. (Pp. 2998; 758 illustrations, 54 in colour. £9 12s. 6d.) London: W. B. Saunders. 1946.

Many clinicians must have waited with something like excitement for the third volume of Prof. Bockus's book on gastro-enterology and they will have breathed a sigh of relief now that it has been brought to a conclusion. The three volumes constitute one of the outstanding publications in the last decade of medical literature. Prof. Bockus was responsible for the whole of the first volume, on oesophagus and stomach, but in the second and third volumes he has called increasingly on the help of collaborators. Nevertheless, the book bears throughout the impress of his personality and literary style, and it reads as a unity and not a series of disconnected episodes. It is a tribute to the vigorous school of gastro-enterology which was built up in Philadelphia between the two wars.

Each volume is about a thousand pages in length, and there is a separate desk index for the three volumes. The book is printed on glossy paper and there are numerous illustrations, including a few colour plates; x-ray reproductions are commendably clear. The individual volumes are not too heavy to be handled and read in comfort. With all this it is not surprising that the price is on the high side. Vol. I deals first with history-taking, interpretation of symptoms, and methods of examination. Then follow sections on the oesophagus and stomach, in the course of which peptic ulcer is considered in detail. Vol. II begins with the applied anatomy and physiology of the small intestine and the clinical approach; the remainder of the volume deals systematically with the diseases of the small and large intestine and the peritoneum. Vol. III opens with the study of the anatomy and physiology of the liver, the various diagnostic tests and the pathogenesis of jaundice. Diseases of the liver, biliary system, and pancreas are then considered, and finally a rather heterogeneous collection of leftovers. This is one of the few textbooks that give an adequate account of modern views on jaundice and hepatitis.

We have used this work for reference ever since the first volume appeared, and it comes triumphantly through that most stringent of all tests, though we were a little surprised to find no mention of aspirin as a cause of haematemesis. The bias is medical, with a recurrent emphasis on the psychiatric and constitutional factors in gastro-intestinal disorders, but most gastro-enterologists will feel that this is as it should be. This is not to deny that Bockus is often dogmatic and that many of his views will not be generally acceptable. He is ultra-conservative in the treatment of peptic ulcer and he pours a cold douche on the concept of gall-bladder dyspepsia. Nevertheless we are bold enough to assert that medicine, like history, is best presented with a bias so long as the bias is consistent and recognizable. It is probably true to say that there is no book comparable with this in any other department of medicine. It is both compendious and generally useful. That is because gastro-intestinal disorders are extremely common. In no other system are there so many acute and chronic disturbances of function, in no other system must the student more frequently be reminded that the whole is greater than the part and that local symptoms are often due to some general constitutional or mental disorder. At times many of us have lamented the excessive concentration on gastro-intestinal disease in the teaching hospitals, but if the patients are studied on the lines laid down by Bockus, the student will find that he has had a valuable discipline in history-taking, applied physiology, and psychology which will profit him over the whole field of medicine.

LEPROSY

Leprosy. By Sir Leonard Rogers, M.D., F.R.C.P., F.R.C.S., F.R.S., and Ernest Muir, M.D., F.R.C.S. Ed. Third edition. (Pp. 280; illustrated. 25s.) Bristol: John Wright and Sons. 1946.

Only six years have elapsed since the appearance of the second edition of this, the classical British treatise on leprosy, but we regret to add that this comparatively short incubation period principally due to enemy action which destroyed a large part of the existing stock. However, Sir Leonard Rogers and Dr. Muir have made good use of the opportunity afforded them of bringing the whole work up to date. It is slightly enlarged and the number of illustrations is now 88.

In these happy isles few people realize the enormous and serious burden of the leprosy problem upon humanity, for a study of the authors' chapter on the distribution of the disease shows that apparently the British Isles and parts of Western Europe are the only areas in which the disease never originates, though cases may be accidentally imported from time to time. In every other part of the world leprosy takes its toll of life and health, and in some countries the leper population numbers many thousands. The pre-eminently bad areas are essentially characterized by low altitude and high rainfall. Nevertheless, owing to the introduction of modern methods of dealing with the disease, which are almost entirely the fruit of Sir Leonard Rogers's work, the problem has taken on a much more hopeful aspect during the last quarter of a century. For the most part compulsory segregation of lepers in prison-like institutions has been abandoned and reliance is placed on a combination of out-patient clinics for non-infective cases and voluntary isolation of those in the infectious stages. The recovery, or at least the improvement, of the patients becomes the best possible advertisement for the treatment offered, and there is now little difficulty in getting the sufferers to apply for admission in the earliest stages of the disease. The results that can now be obtained by skilful management are well exemplified by the history of the island of Nauru in Oceania. The disease was introduced in 1912 and by 1925 a systematic examination of the population showed that 30% of the islanders were infected. Fortunately, however, 90% of the patients were in the early stage of the neural type and could be treated as out-patients. The infective lepromatous sufferers, numbering 193, were isolated. By the year 1933 (there are no later figures) the infective cases had been reduced to 66 and hardly any of the early uninfected cases had gone on to the infective stage without treatment. Nevertheless the control of leprosy remains one of the great tasks to be undertaken by public health authorities both in the Tropics and elsewhere.

All who are interested in the subject, whether from the clinical or the administrative side, should study this volume with the greatest care.

ANAESTHESIA FOR BEGINNERS

Anaesthesia in General Practice. By Stuart C. Cullen, M.D. (Pp. 260; illustrated. \$3.50 or 21s.) Chicago: Year Book Publishers; London: H. K. Lewis and Co.

Too many part-time anaesthetists base their practice of anaesthetics on miscellaneous scraps picked up in student years or on odd visits to colleagues. When the beginner turns to publications he easily falls between the cram books for the D.A. on the one hand, only to be digested with midnight oil, and a vast literature in innumerable journals on the other, delectable though they may be to the specialist. It is therefore a pleasure to find in Dr. Cullen's book a patently honest attempt to help and guide the serious beginner in anaesthetics. The language may be a little stilted and the value of the cartoons doubtful, but the book on the whole is a brave effort. The author rightly remarks in the preface that the main emphasis is "placed on establishing a basis for a rational approach to the problems of using depressive drugs, alleviating respiratory depression and treating shock."

To enumerate the many excellent features of text and illustrations would be an easy task were space available. That there is a chapter of 28 pages headed "Airway" should be sufficient evidence that the title of the book does indicate its contents. Not only the G.P. but the specialist, too, will benefit from its perusal. After all, there is but one important kind of anaesthesia—safe anaesthesia. The beautiful binding and clear type, no less than the text, will grace the bookshelves of any anaesthetist.

Notes on Books

Anatomical Eponyms, by JESSIE DOBSON, M.Sc., of Manchester, is an important book of reference, which has been published at a period when such an historical record will be of special value as an accurate register of the names of those distinguished anatomists, surgeons, and anthropologists who are still fresh in the memory of the older type of anatomical teacher, many of whom have been able to combine scientific work with the practical business of teaching or general surgery. In the preparation of this work there has been recorded, with each name that has been listed, the place and date of birth and death, and a selection of important posts held by the individual; finally the reference to its description in the author's works is given. An excellent portrait of Andreas Vesalius appears as a frontispiece, and the book is sponsored by a foreword written by Prof. Wood Jones, who comments on the danger which exists at the present time of the science of anatomy being deprived of that interest which the association of particular organs or parts of the body with the name of a distinguished anatomist formerly provided. Fortunately a few standard works on anatomy still retain the names of some well-known classical celebrities such as Achilles or Julius Caesar, and of some distinguished surgeon-anatomists. Thus the science of anatomy is not yet entirely bereft of the practical interest inherent in the individual description of such a structure as the perineal (not "peroneal") fascia of Colles, which is of such importance in the limitation of the spread of extravasated urine. The book is published by Baillière, Tindall and Cox at 30s.

A Practical Handbook of Midwifery and Gynaecology, by W. F. T. HAULTAIN and CLIFFORD KENNEDY, needs no re-introduction. The fact that it has reached a third edition, the publication of which was delayed only because of the war, is sufficient testimony to its worth. New features include a chapter on the infant, and sections on the use of drugs in labour, the therapeutic use of hormones, and the use of x rays in obstetrics and gynaecology. It is good to see the incorporation of a note on contraception. This, then, is the ideal revision book for the final-year student. All the answers are here, listed in logical sequence. It is the "ready reckoner" for the busy general practitioner who desires to look up points with a minimum of inconvenience and delay. It should prove to be what the returning Service medical officer is looking for as regards his theoretical rehabilitation in midwifery and gynaecology. The publishers are E. and S. Livingstone, and the price is 20s.

A book that has been in active use—and under constant revision—for nearly thirty years has little need of introduction, and a warm welcome can once again be assured for Dr. H. C. CAMERON'S *The Nervous Child*, now in a fifth edition. When it first appeared it was necessary to remind the profession that the child had a mind as well as a body. Now, as the author wisely remarks, it is almost necessary to remind the psychiatrist in his dealings with children how often the nervous disturbance is erected upon a physical basis. There have been certain small additions and revisions, but essentially Dr. Cameron's classic remains what it always was—a commonsense approach to a very common series of problems in child medicine. It is published by the Oxford University Press at 10s. 6d.

The third edition of *Sternal Puncture*, by Drs. A. PINEY and J. L. HAMILTON-PATERSON (William Heinemann Medical Books; 15s.), shows evidence of considerable revision of the text. Dr. Piney still makes the collector's approach and is unduly interested in rarities. Few, if any, pathologists will ever see a marrow smear of an erythroblastoma, and few would agree that dimorphic anaemia is distinguished from achrestic anaemia by the absence of free acid in the gastric juice. Nevertheless the book has the pre-eminent quality of readability, and the popularity of this third edition seems assured.

A monograph on *Unequal Ventilation of Different Parts of the Lung and the Determination of Cardiac Output* by Dr. P. E. RAUWERDA, of Groningen, lieutenant in the Royal Netherlands Army Medical Corps, has been issued as a cyclostyled volume of over 150 typed pages, with many reproductions of tables and graphs. A copy can be consulted in the library of the British Medical Association, and the work is obtainable from Messrs. H. K. Lewis and Co., 136, Gower Street, at the price of 35s., plus 7d. postage.

Preparations and Appliances

REPLACING THE IRVING BOX: A NEW SUGGESTION

Capt. H. LEVON, S.A.M.C., writes from Capetown:

I have been prompted to write the following note because of the frequency with which the traditional Irving box used in suprapubic drainage proves unsatisfactory. The following apparatus is in use at 110 Military Hospital, Roberts Heights (Major Lorandos, surgeon specialist, S.A.M.C.). Practical experience necessitated a few alterations to the first "model" and we finally arrived at the apparatus described below.

An old anaesthetic mask of the "closed" variety forms the basis of the box—preferably a mask with an inflated rubber-cushion face-piece. An oval wire ring is made to fit circumferentially about a third to halfway down the mask, and four wire hooks are soldered to the wire—i.e., two on either side. (For thin patients it may be necessary to have two additional hooks soldered at the lower portion of the ring.) A 1/4 in. diameter rubber catheter with an extra

A=Tight-fitting cork. B=Metal ring, with hooks. C=Optional hook. D=Catheter. E=Elastic. F="Elastoplast." G=Inflation tube.

hole cut alongside the end (so as not to destroy the tip, which provides necessary rigidity) is then introduced through a corresponding hole cut or burnt into the most dependent part of the mask—i.e., the part nearest the pubis. This hole can be reinforced internally and externally if necessary, to prevent the catheter slipping out, by the use of rubber solution over linen-thread binding. A cork, fitting into the metal top of the mask, completes the apparatus.

To keep the apparatus in place, four strips of "elastoplast" about 1 1/2 in. wide are strapped on either side of the patient's abdomen, passing from either side of the spine to halfway round the flank. Holes are made in the doubled-over ends, and from these pieces of 1/4 in. garter-elastic are stretched to the hooks on the mask. The edge of the box and the skin around the wound are smeared lightly with zinc and castor oil and inel. benz. co. cream to seal the box and to protect the skin. By removing the cork, the wound can easily be inspected and/or swabbed. The additional lower hooks on the wire ring, mentioned above, can be used to keep the box firmly over the pubis (a necessity in thin patients with protuberant pubes) by using a T-bandage between the legs and two further elastic strips.

The advantages of the box are: (1) Water-tightness around the wound, preventing any leak. (2) The apparatus can be adjusted to prevent pouting of the wound, which delays healing. (3) The cushioning effect of the mask is important for the patient's comfort. (4) Little attention is required once the simple apparatus is correctly adjusted. This type of "box" could form the basis for a commercial production.

Thanks are due to the O.C., 110 Military Hospital, and to the D.G.M.S., for permission to publish this note.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 12 1946

MEDICINE'S GREATEST GIFT

It was Sir William Osler who referred to surgical anaesthesia as medicine's greatest single gift to suffering humanity. The centenary of the first practical application of the method falls on Oct. 16, 1946. The centenary is being celebrated by exhibitions at the Royal College of Surgeons and at the Wellcome Historical Medical Museum illustrating the history of anaesthesia throughout the ages; by celebrations organized by the Society of Anaesthetists; and by special meetings at the Royal Society of Medicine and elsewhere. In the present issue we have tried to blend the old news with the new in a small symposium in the opening pages of the *Journal*. A recent number of the *British Medical Bulletin* worthily commemorated the event whose birthday falls due next week.

The history of anaesthesia provides a good example of the necessity for advances being made in certain sciences before any steps can be taken in others. Medical men had always sought some agent to deaden the pain of surgical operations, and it is understandable that for centuries the drugs used were nearly always taken by mouth. Whether the essential constituent of the substance administered was opium, or atropine, or hyoscyamus, it is obvious that there could not have been any true anaesthesia. The best that could be hoped for was some dulling of the sense of pain. In the Middle Ages there arose the practice of "inhaling" so-called anaesthetic substances, as, for example, those contained in the "soporific sponge." But most of these substances were non-volatile, and there could be no true inhalation anaesthesia. Medicine had to await the development of chemistry before any true anaesthesia could even be conceived. Until about 1754, when Joseph Black announced his discovery of carbon dioxide, the existence of "airs" which were not ordinary air was not recognized. The discovery of many new gases by Joseph Priestley in the period 1770-80 at once made possible the conception of an anaesthetic agent administered in the form of a true inhalation. Nearly seventy years were to pass before the logical outcome of these discoveries was the successful use of a gas or vapour for anaesthetic purposes.

At this time we do honour to all those who made possible the use of the new method in surgery. Despite the statues erected to his memory, Crawford W. Long had no influence on the development of the method, although he himself used ether as a general anaesthetic in quite a number of cases from 1842 onwards. To Horace Wells and W. T. G. Morton goes most of the credit. These men were totally different in character and mental make-up. They were both dentists, but there similarity ceased. Had not Wells been something of a dreamer he might never have demonstrated

the anaesthetic properties of nitrous oxide. But, on the other hand, had he been a practical and ambitious man like Morton, he might have established for some time the use of nitrous oxide. Ether and chloroform would naturally have taken their proper places later, but from many aspects it was perhaps better that Wells failed and Morton succeeded. It was a pity that Morton tarnished the brightness of his great practical achievement by subsequent action. Had he not been linked with jealous and unscrupulous Jackson his commercial attitude to the question might have been modified.

The subsequent history of anaesthesia in the 'fifties and 'sixties was dominated by the ether-chloroform controversy. It is strange that nitrous oxide, the first inhalation anaesthetic, should have been neglected for nearly sixteen years. The emphasis on ether and chloroform did more; it delayed the adoption or discovery of new anaesthetics which the present century have done so much to widen the horizon. However, the advent of professional anaesthetists and the whole-hearted co-operation of instrument manufacturers enabled progress to be made in the design of apparatus. Such men as Snow and Clover, starting as they did with considerable experience in other fields, gave this branch of the medical art something of the dignity of an exact science. The work of the French physiologists Magendie, Flourens, and Claude Bernard among others lent the final polish. Paul Bert, another great French worker, did much to clarify the position regarding the pressures of anaesthetic vapours, and, though his conception of a "pressurized" operating chamber receded into the background after being used for some time in France, the laws which he taught bore fruit later. The numerous inhalers which were invented during the second half of the nineteenth century constitute a maze out of which only an expert can find his way. In this issue an illustrated summary of the most important types of apparatus is given.

It is a curious reflection that, while from the period of its real beginning in 1846 until about the period of the war of 1914-18 anaesthesia was largely inhalational, during recent years there has been an increasing tendency to employ drugs given by other routes. It will be recalled that when Morton gave ether in his fourth case at the Massachusetts General Hospital—that is, his first really major operation, the amputation of the leg of Alice Mohan—the surgeon was so sceptical of the value of the anaesthetic that he had given the patient 100 drops of laudanum before the operation. This was premedication with a vengeance. Since then premedication has made many advances, and the field has widened to include the practical use of anaesthetics administered by non-inhalation methods. Such methods depend upon those pioneers who devised methods of introducing drugs into the body via the subcutaneous tissues or the circulation. Lafargue injected morphia paste subcutaneously in 1836, and in 1839 Taylor and Washington of New York introduced hypodermic injections for the relief of pain. In 1853 Wood of Edinburgh invented the hollow needle, and in the same year Pravaz used this needle in conjunction with a special syringe of his own design. Twenty years later Bennett showed that cocaine had anaesthetic properties, and the whole prospect of local anaesthesia was opened up. In 1875 the

appeared the first monograph on intravenous anaesthesia, P. C. Oré's *Études cliniques sur l'anesthésie chirurgicale* . . . which described the use of chloral hydrate by this method. Shortly afterwards various investigators tackled the problem of introducing anaesthetic substances directly into the cerebrospinal fluid. In 1899 Rudolph Matas was one of the first to make satisfactory use of the method in the human subject. Rectal anaesthesia was attempted by Pirogoff as far back as 1847, and this method first achieved practical possibilities in the hands of Mollière in 1884. A word should be said about the development of endotracheal administration. In 1869 Trendelenburg administered chloroform by this route, but only after performing tracheotomy on the patient. Sir William Macewen of Glasgow was the pioneer of endotracheal anaesthesia without preliminary tracheotomy, since in 1880 he passed a metal tube into the trachea through the mouth, and administered chloroform by this route in a case of malignant disease of the base of the tongue. This led ultimately to the methods of Magill and Rowbotham, which were inaugurated during the first world war.

Many drugs have been tried for anaesthetic purposes. One of the earliest was ethylene. This was first tried in 1849 by Thomas Nunneley of Leeds. His results with ethylene were unsatisfactory, but much better with ethylene dichloride. It was Nunneley who first described the A.C.E. mixture. The period from 1918 to 1922 was marked by the researches of Luckhardt and Thompson, which established ethylene as a practical possibility. Cyclopropane was first discovered by August Freund in 1882, and its utility as an anaesthetic was established by Lucas and Henderson in 1928. The most recent experimental work prompts repetition of the words of the prophet that there is no new thing under the sun. Baron Larrey, Napoleon's military surgeon, had observed the anaesthetic effect of extreme cold after the battle of Eylau, and he recalled this observation in a discussion at the French Academy on Hickman's Memorial to Charles X. It is now recognized that amputation of a limb can be performed with no other anaesthetic than efficient refrigeration of the affected member. In this number recent advances in anaesthesia are discussed in a special article. In the past there was difficulty in securing satisfactory statistics for anaesthetic purposes; but in recent years advances have also been made in keeping records.

Efficient anaesthesia has long been an established practice. While anaesthetics have become increasingly safe in the hands of experts, something still remains to be done. The work of the pioneers which we recall to-day should be an inspiration to the pioneers of to-morrow.

JUDICIOUS ENDOWMENT

The trustees of the Nuffield Foundation, which was established by Lord Nuffield three years ago as a charitable trust with an endowment of ten millions, have published their first report. The Foundation has three main objects: the advancement of health and prevention and relief of sickness, in particular by medical research and teaching and by the organization of medical and health services;

the advancement of social wellbeing; and the care and comfort of the aged poor. The board of trustees includes two members of the medical profession—Sir John Stopford and Dr. Janet Vaughan.

The Foundation welcomed the opportunity of co-operating in London University's plans for the creation of the Institute of Child Health, and it endowed the professorship with a sum of £100,000, payable in equal instalments over ten years. It has assisted the Universities of Durham, Glasgow, and Manchester in their plans for the development of teaching and research in the field of industrial health; the former two have accepted grants totalling to £40,000, and Manchester to £70,000. The Foundation has also offered a number of medical fellowships in industrial medicine, social medicine, psychology, and child health, of an annual value of between £500 and £800 each and tenable for from one to three years. A different and less academic project designed to advance industrial health has also been aided. This is a combined industrial health, rehabilitation, and research service to be established at Slough. The provisional plans include an industrial health centre giving expert advice on conditions in factories and workshops, a casualty clinic, an out-patient rehabilitation department, a remedial workshop, and a research department studying causation and incidence of disease in light industry. The Foundation has promised a grant of £3,000 a year for five years towards the research side of the scheme. Large benefactions have been made for the furtherance of dental health: a sum of £150,000 has been assigned for the whole programme, which includes a scheme of fellowships and scholarships to encourage persons of suitable ability to prepare themselves for an academic career in dentistry, and also assistance to certain dental schools to improve the quality of dental teaching and the facilities for research. The schools assisted are the Sutherland Dental School of the University of Durham, Guy's Hospital Dental School, the School of Dentistry of the University of Leeds, and the Turner Dental School of the University of Manchester. Other projects aided are research in ophthalmology, in rhinology, and in radiology. A grant of £3,000 a year for three years has been made to the University of Oxford in aid of the Nuffield Laboratory of Ophthalmology, and a grant of £3,700 has been allocated to the University of Manchester and the Manchester Royal Infirmary for research on the causation of catarrhal infection in the nasal passages. The grant for radiological research is to finance certain investigations proposed to be carried out at the Nuffield Institute of Medical Research at Oxford into the normal structure and functions of the human body as revealed by radiography and x-ray cinematography.

Apart from medicine, the Nuffield Foundation has made large grants to stimulate research in the fields of nuclear physics, agriculture, and metallurgy. Among the allocations for the furtherance of the social sciences is a grant of £5,000 a year for five years to the Population Investigation Committee towards the cost of its programme of research. The programme includes a survey of population trends, an inquiry into certain aspects of child-bearing and of the maternity services of Great Britain, a study of the factors influencing age at marriage, and inquiries into the relation between fertility and intelligence. The subsequent

appointment of the Royal Commission on Population has not restricted the work of this committee, which was originally set up in 1936, but on the contrary has widened the possibilities of its useful work. Finally, in pursuit of its third aim, the Foundation has initiated a survey of the problems of ageing and of the care of aged people. Grants have been made in support of two projects of research into the process of ageing, one by the Department of Psychology of the University of Cambridge, into the characteristics and changes of human function associated with different age-groups, and the other a series of clinical trials carried out at Tooting Bec (L.C.C.) Hospital by the Club for Research on Ageing.

The total amount expended by the Nuffield Foundation during the first three years of its existence has been little short of a million pounds, but the policy behind the allocations has been as wise and discerning as the allocations themselves have been princely—a thing which cannot be said of all large-scale philanthropy.

ACCELERATION OF WOUND HEALING

During the recent war, and more particularly in the semi-tropical and tropical campaigns, wounds, burns, and ulcers often showed an indolence not commonly observed in civil life. Frequently the wound or ulcer, though affecting an apparently healthy and well-nourished soldier and though entirely or almost free from infection, remained for weeks or months without decreasing in size and with little evidence of an ingrowing epithelial edge. The patient and his medical attendants became impatient of this indolence, and for the stimulation of healing every practicable measure was employed which theory could justify or ingenuity devise. Kerr and Werner,^{1,2} for example, using a heart-extract powder which had been prepared by Doljanski³ and which had shown a remarkable capacity for promoting the growth of fibroblasts and epithelial cells in tissue culture, applied their preparation to eighty indolent wounds, burns, or ulcers; and a conspicuous acceleration of healing was observed in all but seven cases. This remarkable success demanded further investigation, not only because of its clinical importance but because of the far wider biological implication that heart-extract powder promotes the healing of indolent wounds by virtue of its capacity to stimulate the growth of fibroblasts and other cells *in vitro*.

Young, Cruickshank, and Martin⁴ have made a detailed, carefully controlled, and statistically complete study of the effect on wound healing of heart-extract powder prepared after the method of Doljanski. They followed the progress of healing in four hundred and sixty-two experimental wounds of rabbits and guinea-pigs. The heart-extract powder (prepared from the adult sheep heart) and embryo-extract powder (from the whole sheep embryo), applied directly to the surface of healthy wounds in these experiments, consistently *retarded* the healing process; and they conclude that there is no direct correlation between growth-promoting capacity *in vitro* and that *in vivo* in so far as the healing of healthy wounds can be accepted as a criterion. The heart-extract powder exercised no general or constitutional effect on the healing of distant wounds and was not anaphylactogenic, as Werner has suggested. Applied directly to the surface of a wound, heart-extract powder evokes a non-

specific, foreign-body, giant-cell reaction similar to that evoked by Scharlach R and Sudan III, which enjoyed vogue some thirty years ago as stimulants to healing indolent wounds. Young, Cruickshank, and Martin suggest that in the series published by Kerr and Werner at least sixty-three of the patients (and possibly more) had been treated more or less intensively with sulphanilamide for prolonged but variable periods up to 270 days, and suspect that one at least suffered from sulphonamide poisoning the time when sulphanilamide was stopped and treatment with heart-extract powder begun. They think it regrettable that Kerr and Werner were unable to employ a series of "sulphonamide controls" in their clinical experiments.

The work of Young and his colleagues is of great importance in demonstrating clearly the negative but fundamental axiom that a substance cannot be assumed to stimulate in the human body the growth of those tissues whose growth it accelerates in tissue culture.

PERIODICITY OF INFLUENZA EPIDEMICS

The possible appearance of a major influenza epidemic has been the subject of much speculation during the past few years. Early in the war a large outbreak was due if the previous cycle of appearance was used as a basis of prediction. Yet despite this and the apparently favourable circumstances of overcrowded shelters, exposure to cold and damp, lack of sleep, and so forth, influenza did not assume the proportions of a major epidemic.

There is an apparent underlying law of periodicity governing the occurrence of large outbreaks, and much work has been done in an attempt to determine the influenza cycle. So far, however, no method has been able to predict future outbreaks except for relatively short periods. Up to 1939 influenza epidemics in this country had a two- to four-year cycle, and the years when the disease reached epidemic proportions were 1922, 1924, 1927, 1929, 1933, and 1937. Although there has been no large outbreak since 1937, a fairly sharp rise in mortality was recorded in 1940 and again in 1943. Various attempts to describe the periodicity of influenza have generally failed because of the non-appearance of an outbreak. Brownlee demonstrated a 33-week cycle but excepted those years when the prediction fell in summer and autumn, since the outbreak failed to appear in these months. Other workers have tried to forecast a future outbreak from the period of the year when the last epidemic occurred. This procedure gave a good description of the major outbreaks over past experience. Influenza seems to have been more variable in the time of its appearance than has been the case in recent years. During the last decade the seasonal rise in incidence has always been recorded in the first few weeks of the year, except in 1943 when it began about ten weeks earlier than usual. With a constant period of maximum incidence the prediction of epidemics should have been relatively certain if the hypothesis was true, but the forecasting of major outbreaks remains unsolved.

The epidemiology of influenza in America is similar to that in England, although sharp differences exist between the trends in these and in other countries. Climate and other environmental factors influence the course, severity, and frequency of influenza epidemics. The latest contribution to the study of periodicity is by the Commission of Acute Respiratory Diseases, at Fort Bragg in North Carolina.¹ These workers have approached the problem from a new standpoint. They consider that major outbreaks of influenza follow not a simple curve but a

¹ *Brit. J. Surg.*, 1944-5, 32, 231.

² *Ibid.*, 1944-5, 32, 518.

³ *Nature*, 1942, 150, 660.

⁴ *J. Path. Bact.*, 1946, 53, 63.

¹ *Amer. J. Hyg.*, 1946, 43, 29.

mplex one with at least two main factors. Since the discovery of viruses A and B, epidemics in the United States have since 1932 been associated with one or the other of these types. That two serologically distinct viruses may cause epidemics was unknown to earlier epidemiologists, and any suggestion that the periodic curve of influenza showed two different components would probably have been derided, as were Brownlee's different measles periodicities for North and South London. Examination of recent American outbreaks indicates that virus A may have a variable interval of two to three years and virus B a cycle of four to six years, and the Fort Bragg team applied this theory to epidemics preceding 1932. They found that their hypothesis did not give an exact method of prediction but showed the probability of occurrence within rather wide time limits. The limits of prediction by this method do not appear to be any smaller than those of the older methods. It was forecast "that influenza A will reappear during the winter of 1945-6. If it fails to occur in this season, the probability is much greater that it will appear in the following winter." This finding is similar to that postulated here last autumn, and so far as Britain is concerned the longer the interval since a large outbreak the greater the probability that the next seasonal season will reach epidemic proportions. No evidence was found in the mortality trends that hypothetical viruses, influenza Y or type C, have caused widespread outbreaks in the past twenty-five years. This finding does not, of course, exclude the possibility that a type of influenza exists that appears at long intervals and produces pandemics such as that of 1918. It is quite possible, too, that mortality shows a large variation between different outbreaks and that a widespread outbreak may occur without a rise in mortality, which might account for some of the apparent irregularities in the influenza cycle. The Commission have examined this point and can find no evidence to support such a hypothesis.

INEQUALITY OF THE PUPILS

Pupillary inequality is a common clinical finding which may or may not have diagnostic significance. The fact that affections of both the sympathetic and the parasympathetic systems cause anisocoria adds to the difficulties of the clinician; and the problem may be complicated by the possibility of local abnormalities in the iris itself, the innervation being intact. Accurate clinical testing requires standard conditions of illumination and measurement—far from simple provisions.

The problem of pupillary inequality can be studied by the method of collyria—the use of eye-drops—whereby the duplex nerve supply of the iris can be either stimulated or inhibited. This line of investigation, first suggested by Coppez in 1903 and described by him many years later in collaboration with Danis,¹ has been pursued recently by E. A. Turner² with promising results. Turner used a solution of 4% cocaine in 1:1,000 adrenaline. Four drops are instilled into each eye at half-minute intervals. Then every fifteen minutes the size and equality of the pupils are noted as well as their reactions to light and accommodation. Five readings are taken. His series was made up of 50 normal controls and 66 heterogeneous cases of anisocoria. It was considered that this test was of assistance not only in bringing out latent inequalities of pupil but also in determining their morbid anatomical nature. A partial third nerve paresis without external ophthalmoplegia was found to be the commonest cause of anisocoria after a recent head injury.

¹ *Rev. Ocul-Neuro-Otol.*, 1926, 4, 51.
² *Brain*, 1945, 68, 93.

The test proves to be of help to the clinician in three sets of circumstances: (1) where the side of the lesion is known the cause of the pupillary inequality can be determined; (2) where the side of the lesion is obscure but the system involved is known the nature of the lesion can be ascertained; and (3) where neither the affected side nor the system involved is known the nature of the lesion can be determined with confidence in cases of well-marked oculomotor palsy, and of long-standing oculosympathetic affection. In both these conditions the difference in size of the pupils is increased, but in the former the pupils remain circular and respond by dilatation, while in the latter the affected pupil becomes small and irregular.

EXPERIMENTAL GONORRHOEA

The scientific investigation of gonorrhoea has always been handicapped by the fact that no animal naturally susceptible to infection has been available. Mahoney, Van Slyke, Cutler, and Blum¹ described recently an attempt to discover a satisfactory method of infecting human volunteers. Since this attempt failed, they could not go on, as they intended, to investigate the effectiveness of various prophylactics. Nevertheless, their account of the various methods employed is instructive. Certain facts which emerged may be recapitulated briefly. Cultured strains of gonococci failed to cause clinical disease with any consistency, and the older the strain the less likely it was to prove effective. The most successful method of conveying infection was by transferring pus from an acute case directly to the urethra of a volunteer, but even this method sometimes failed to infect. A heavy inoculum, deep insertion into the urethra, and the use of mucin or peptone solution rather than saline—which was shown to be toxic to the gonococcus—increased the chances of success. Patients infected with sulphonamide-resistant strains did not respond to sulphonamide therapy but were cured by penicillin. Those with a positive seemed less liable to infection than those with a negative complement-fixation test, and the same applied to volunteers with a previous history of gonorrhoea. The incubation period of experimental gonorrhoea averaged 3 to 5 days, with extremes of 1 and 31 days. When originally examined 1% of the volunteers harboured typical gonococci without showing clinical signs, and were therefore carriers.

This article contains a wealth of information and will well repay study by all who have to do with the management of gonorrhoea. The experiments and their results are set out clearly; five tables summarize the findings; and three appendices give, respectively, details of the bacteriological technique, the colony morphology, and the history of the strains of organisms employed. Altogether, this may be regarded as one of the most valuable contributions to the subject of experimental gonorrhoea which has been published.

Dr. D. Evan Bedford will deliver the Bradshaw Lecture before the Royal College of Physicians of London on Thursday, Nov. 7, at 5 p.m. at the College, Pall Mall East. His subject is "Hypertensive Heart Disease."

Amer. J. Syphil., 1946, 30, 1.

The Committee of Privy Council for Medical Research has appointed C. A. B. Wilcock, M.P., C. A. Lovatt Evans, D.Sc., F.R.C.P., F.R.S. (Jodrell Professor of Physiology in the University of London), and R. A. Peters, M.D., F.R.S. (Whitley Professor of Biochemistry in the University of Oxford), to be members of the Medical Research Council.

ROYAL COLLEGE OF OBSTETRICIANS AND
GYNAECOLOGISTS

Lord Woolton was the principal guest at a dinner held by the Royal College of Obstetricians and Gynaecologists on Sept. 27—the first since 1938. Mr. Eardley Holland, who presided, introduced Lord Woolton as someone who had always been interested in the maternity service of the country. As Minister of Food he had early turned his attention to the diet of the expectant mother. Lady Woolton had started the first infant welfare clinic in this country.

In proposing the toast of the College Lord Woolton recalled his close friendship with the late William Blair Bell—"an extraordinary man he was." He remembered Blair Bell at the time when he was made President of the College—"a great dynamic force searching out for new things." Lord Woolton was associated with him in his search for a cure for cancer—"we found out the negative." He recalled Blair Bell telling him in his study his dreams for the College; and the dreams had now come true. Lord Woolton said that one of the first maternity clinics in the North had been started by his wife and himself. When he took on the job of Minister of Food in the early days of the war he determined to do something for the infant-life of the country, and the success he attained was made possible by the excellence of his advisers—Lord Horder as his medical adviser and Prof. J. C. Drummond as his scientific adviser. There was, he concluded, no wiser expenditure of money than that devoted to the health and welfare of the infant life of the country. Mr. Eardley Holland, responding to the toast, said that this was the 17th birthday of the College. This year the Queen had done them the honour of becoming Patron of the College and he hoped that this year the King would present it with a Royal Charter. In 1938 the membership was 580, and this year it was 775. They were an Empire College, no less than 1/4 of the fellows and 1/3 of the members working in the Dominions. Mr. Holland referred to the work of the special committees of the College on various aspects of obstetrics and their investigations on behalf of the Royal Commission on Population.

Antenatal Clinics: Message from the Minister

The President read the following letter from the Minister of Health:

Dear Mr. Holland,—Thank you for your letter of Sept. 20, and for your kind remarks about my speech at the lunch the other day. I hope the following information is what you want for the 27th.

We have always envisaged that in staffing their antenatal clinics, local authorities must enlist the co-operation of the Regional Board, and that this will be done by appointing one of the hospital obstetricians as officer-in-charge of each of the local antenatal clinics. This would enable the obstetrician to determine whether the mother will ultimately require admission to hospital (and to take the necessary steps accordingly) or whether she can be left to the care of the midwife, with the facilities of the hospital or the services of an obstetrician or experienced general practitioner always available in the background. This arrangement would ensure also that the social services of the local authority in the shape of the health visitors would be at the disposal of the obstetrician in the clinic, and similar service will, of course, be at his disposal by arrangement with the local authority in the hospital. But above all we must remember that the general practitioner is one of the chief co-ordinators of the service. He is the manager who produces for the benefit of his patient all the facilities which the National Health Service can offer. He will have contacts with all the working parts of the machine—the hospital, the clinic, the health centre, and the services of the local authority, and will personally know the men and women who staff them.

We have still a good deal to do in planning out the precise details of the organization, but these are the main lines along which it will be developed.—Yours sincerely,

ANEURIN BEVAN.

Mr. Eardley Holland concluded with a note of welcome to the succeeding President, Mr. William Gilliatt, C.V.O., F.R.C.S. Mr. A. A. Gemmell gave a pleasant speech of welcome to the guests. In response Sir Hugh Lett praised the work of the College and stressed the need for a united profession if its voice was to be effective in dealing with those in authority. He pleaded for a closer unity between the B.M.A. and the Royal Colleges, whose work was primarily academic.

RETIREMENT OF THE SCOTTISH SECRETARY

Dr. R. W. Craig retires from the position of Scottish Secretary of the B.M.A. after holding that responsible post for 15 years. On Friday evening last week a reception and dance were given in the Scottish Office of the B.M.A. in Edinburgh in his honour. During the course of a very enjoyable evening Dr. J. B. M. Chairman of the Representative Body, presented Dr. Craig with a cheque as a token of esteem from a wide circle of friends and colleagues. Others who spoke in appreciation of Dr. Craig (and of Mrs. Craig) were Dr. A. F. Wilkie, Mr. Dr. Charles Hill, and Dr. J. F. Lambie. Among those present on this occasion was Dr. T. C. Routley, Secretary of the Canadian Medical Association.

In acknowledging the presentation and the many kind things that had been said about him, Dr. Craig gave an interesting review of the work of his Office and ended by extending a warm welcome to his successor, Dr. E. R. C. Walker. Some interesting comments on the future of the National Health Service in Scotland, Dr. Craig observed that the Scottish Bill would be submitted to the House of Commons before many weeks had passed. It was idle to pretend, he observed, that there was complete agreement between the Minister of Health and the medical profession as a whole. There was general agreement on the part of the Government and the medical profession as to the aims of the Act. The differences arose as to the methods adopted by the Government to put the scheme into operation. The opportunity at the present time of effecting a much-needed improvement in the health service of the country was great. It was his fervent prayer that the satisfactory solution of the present difficulties would be found. The Government must allow the doctors to remain "captains of their souls."

Those who met together last week to say hail and farewell to Dr. Craig must have felt much indebted to the Scottish Committee, which, under the chairmanship of Dr. A. F. W. Millar, blended formality and friendliness in an evening well proved once again that the Scots are the most hospitable people in the world.

MIDDLESEX HOSPITAL MEDICAL SCHOOL DINNER

The annual dinner of the Middlesex Hospital Medical School, held at the Savoy Hotel on Oct. 4, Dr. G. E. Beaumont presided. In proposing the toast of the "Middlesex Hospital and Medical School" Dr. Beaumont ranged with unerring wit from osteopaths to plastic belts. Replying, the Dean of the Medical School, Dr. H. E. A. Boldero, mentioned that the Hon. J. J. Astor, chairman of the Board of the hospital, had also become chairman of the School Council. The two posts had never previously been occupied by one person. He welcomed back demobilized officers and students but regretted that for the first time the Middlesex had been unable to keep its promise to parents to admit boys direct from school. He felt strongly that men embarking on a professional career should in future be allowed to complete their studies and undertake military service after qualifying. It was intended to increase the annual entry to the school from 80 to 100, and he hoped that the possibility with regard to the admission of students would improve. A senior Broderip scholar, Dr. J. Marks, also replied. Sir Gordon Gordon-Taylor proposed the health of the chairman, and in responding Dr. Beaumont was able to announce that his earlier reference to the difficulties of the rowing club had not fallen upon stony ground. Sir Alfred Webb-Johnson, President of the Royal College of Surgeons, had in the course of the dinner agreed to present the club with a new boat.

The Diagnosis Section of the Faculty of Radiologists will meet on Friday, Oct. 18, at 2.30 p.m., at the Royal College of Surgeons, Lincoln's Inn Fields, when Dr. Solve Welin, of Stockholm, will speak on "The x-ray diagnosis of cholelithiasis in the tempo bone," followed by Dr. H. Graham Hodgson. The following radiological meetings will also be held in London: British Institute of Radiology, 32, Welbeck Street, W., Oct. 17, 8 p.m. Dr. R. Spiegler: "The radiograph from the physicist's view point." Radiological Section, Royal Society of Medicine, 1, Wimpole Street, Oct. 18, 5.30 p.m. Presidential address. Dr. S. Whately Davidson: "A basis for staffing a radiological department." Reports from the *British Journal of Radiology* of the discussion on "Melanomatous" by Prof. P. J. Moir, etc., are now available (10s. each) from the secretary of the Faculty of Radiologists, Lincoln's Inn Fields, W.C.1.

Modern Salicylate Therapy

ALTHOUGH acetylsalicylic acid is one of the most popular and effective non-narcotic analgesics available, its use has frequently been discarded by the physician in view of the possibility of its irritating the gastro-intestinal tract.

'Alasil,' however, helps to overcome this objection by providing the beneficial therapeutic effects of acetylsalicylic acid in such a form that it is acceptable, even by delicate or disordered digestions. This tolerability is due to the fact that 'Alasil' combines acetylsalicylic acid with Dibasic Calcium Phosphate and 'Alcol,' an effective gastric, sedative and antacid.

For these reasons, 'Alasil' is an analgesic, antipyretic, and anti-rheumatic which can be administered with complete confidence in all the conditions in which such an agent is indicated. It is so well tolerated that its use can be pushed to the desired extent.

Alasil

Some Vulgar Errors in Regard to Goitre

SIR,—May I express whole-hearted agreement with the conclusions of the authors of the excellent and timely paper under the above heading. A long time ago I asked in a letter to you for great caution in the use of thiouracil, and since that time I have been increasingly alarmed at the apparently light-hearted way in which the authors of many recent papers have advocated its use.

I am convinced that for the thyrotoxic patient thiouracil holds out neither so good a prospect of cure of symptoms nor such a margin of safety as does surgery in the hands of a competent thyroid surgeon, and I feel strongly that its use should be confined within the limits of pre-operative preparation and the occasional case where surgery is contraindicated or carries exceptional hazard. Finally, the authors of this article ask the question: "Should not every nodular goitre be removed surgically without undue delay?" The answer, I am as convinced as I am sure they are, is Yes.—I am, etc.,

London, W.1.

E. G. SLESINGER.

SIR,—In their article (Sept. 28, p. 449) Dr. J. W. Linnell, Mr. Geoffrey Keynes, and Mr. J. E. Piercy enunciate as Vulgar Error Number IV in regard to goitre "That no goitre should be considered toxic unless the basal metabolic rate is found to be above normal." It is clear from reading the section of which this quotation forms the heading that the words "found to be" are important and that in the experience of the authors the methods of estimating the B.M.R. show too wide a margin of error to allow them to regard this as an accurate test. This may partly be due to the use of single estimations rather than the duplicate or triplicate methods employed nowadays by most careful workers in this field. Nevertheless it does also appear to be the opinion of the authors that the effect of the thyroid on metabolism may not necessarily be fundamental. For example, in discussing the results of toxic goitre they say: "... the toxic process may miss, or almost miss, the metabolic system..." and elsewhere: "There is little doubt that the cardiovascular, nervous, and metabolic systems are all affected to some degree by toxic goitre, but sometimes, for an unknown reason, only one, or it may be two, of these systems are affected to any marked degree." And again: "The point, however, which we especially wish to make is that in the very large and important group of goitres to which we have drawn attention, where the toxicosis is minimal and yet the danger of eventual auricular fibrillation is real, so little is the general metabolism affected as a rule that it is rare to find the basal metabolic rate significantly raised."

It goes without saying that in the hands of such acknowledged experts as the authors the diagnosis of thyrotoxicosis and toxic goitre is safe even if they do not call the B.M.R. to their aid, but I doubt very much whether this would apply to the vast majority of the medical profession. For instance, referring to the symptoms of mild thyrotoxicosis, the authors say: "These symptoms, it may be said, often can only be detected by careful observation, for they may amount to no more than some of the following: lassitude, minor or occasional palpitations, slight irritability or emotional instability, loss of weight, irregular sweatings or feelings of heat, a small rise of the resting or, better, sleeping pulse rate, a fine digital tremor, the suspicion of a starc due to retraction of the upper lids, and an almost imperceptible difference in the size of the palpebral fissures." Is it good teaching, I wonder, to permit the diagnosis of thyrotoxicosis on such findings in the absence of a raised B.M.R.? If so it obviously requires a highly developed degree of diagnostic skill to distinguish between this condition and an anxiety state or, say, the menopause, if there is no obvious enlargement of the thyroid; and if there is enlargement of the gland, to distinguish between non-toxic and toxic goitre. The physiologist, I suppose, still seeks to explain all the symptoms and signs of hyperthyroidism (and he would probably prefer this term to "thyrotoxicosis") as being the result of increased metabolic rate, and would want to be provided with evidence of this in the form of a careful and repeated estimation of

oxygen consumption in comparison with standard figures before he would be inclined to accept the diagnosis.

In the section on thiouracil I find it difficult to follow the arguments of the authors. It is quite clear that one of their principal reasons for not advocating the use of this drug as an alternative to subtotal thyroidectomy is on account of the possible complications, of which they compile the following formidable list. "Headache, nausea, and vomiting—usually transient, but occasionally so severe or prolonged as to cause discontinuance of the treatment—pyrexia, splenic enlargement, various rashes, adenitis, enlargement of the salivary glands, diarrhoea, jaundice, oedema, pains in the joints, leucopenia, thrombocytopenia, agranulocytosis, and myxoedema are some though not all of those which have been described." To this they add the following sinister quotation: "'the thiouracil goitre is more of a cellular hyperplasia with mitosis very much in evidence and so, therefore, more comparable to a carcinoma.'" Now it is the present experience that the complications of thiouracil more commonly present themselves early than late in the treatment. How can the authors therefore justify their advocacy of the use of thiouracil as a pre-operative measure?—I am, etc.,

P. M. F. BISHOP.

Homologous Serum Jaundice

SIR,—In the *Journal* of Sept. 21 (p. 409), Spurling, Shone, and Vaughan record a follow-up, establishing the conclusion that blood transfusion with pooled serum or plasma is associated with a much higher risk of serum-hepatitis than is transfusion with whole blood from individual donors. This conclusion tallies with the results of a follow-up of Army cases recorded by the writers in a paper now in proof (*Brit. J. soc. Med.*) and in a restricted report prepared by us early in the year and circulated last May. In our smaller sample of about 250 in either group the rates for homologous serum jaundice in those who received pooled plasma and whole blood from individual donors were respectively 5.14 ± 2.28 and $0.81 \pm 0.32\%$.—We are, etc.,

Sir Almroth Wright and Anti-typhoid Inoculation

SIR,—I am indebted to Dr. Leonard Colebrook and to Prof. Lyle Cummins for the letters (Sept. 14 and 28) in which they draw attention to what might appear to be a misleading account of the rise of anti-typhoid inoculation in my *History of Medicine* (p. 348).

Although it has seemed to your distinguished correspondents, and possibly to other readers, that I have discussed the relative merits of Sir William Leishman and Sir Almroth Wright in regard to this great discovery, nothing was farther from my intention, and I should be extremely sorry to initiate any controversy in the matter. Indeed I yield to no one in my admiration of the magnificent pioneer work of Sir Almroth Wright in the field of preventive inoculation. My statement that Leishman was responsible for the adoption by the British Army of anti-typhoid inoculation, prior to the Great War, does not in any way detract from the credit due to his distinguished predecessor who originated the method. The researches of Sir Almroth Wright, who is still so happily with us, continue to deserve the highest praise, and I shall endeavour, in any future edition of my book, to state the facts more explicitly so that there may be no risk of misunderstanding in regard to the position of one of our greatest geniuses in bacteriology.—I am, etc.,

Edinburgh.

DOUGLAS GUTHRIE.

The Milk Ration

SIR,—In view of the present drastic reduction in the milk ration I feel sure that many practitioners will join me in protesting against the continuation of the milk priority scheme without modification. If prevention be the basis of modern medicine, we are wandering away from this path to the detriment of the healthy, while in my opinion many of the sick are assured an over-lavish supply.

The continuous supply of two pints of milk a day for persons suffering from gastric or duodenal ulcer can only be justified if

these patients are willing to forfeit the whole or part of the meat ration. It would in fact be reasonable if two pints were allowed during the acute stage with forfeit of the whole meat ration and one pint a day after this period with forfeit of half a meat ration. This same adjustment should be made for all cases of dyspepsia and inability to swallow, etc. Exception should be made in the case of children and expectant mothers and in cases of tuberculosis during the active stage. It will be found that nearly all cases of tuberculosis expect and are in fact allowed an extra milk ration after the disease is quiescent, and this allowance should be reduced to not more than one pint daily.

It is logical to assume that if the quantities of milk are needed in the treatment of these diseases, its presence in adequate amounts is necessary as a preventive measure in the healthy. In my opinion the general effect of such arrangements would be a reduction in the priority claims by a substantial amount. The general practitioner would be materially assisted in assessing the value of patients' sudden inclination to develop symptoms requiring priority milk immediately the standard milk supply falls.—I am, etc.,

Watford,

A. STAVELEY GOUGH.

Smallpox in the Vaccinated

SIR,—Dr. F. K. Beaumont (Sept. 21, p. 437) attributes the frequent failure of vaccination and revaccination to protect personnel in the Forces to the one-mark vaccination advocated by the Government prior to 1944. Possibly three- or four-mark vaccination does give rather more protection than one-mark, though the evidence is not very conclusive, but there is another aspect to be considered. This is that the severity of the reaction is also greater. This question of reaction is very important. Dr. Beaumont quotes from his own recent experience the case of a sailor (who bore good marks from infant vaccination) who had such a severe reaction that he had a temperature of 104° F. (40° C.) for three days, and his arm took six weeks to heal, leaving a scar the size of a half-a-crown. One hopes that such cases are very exceptional, but they can hardly popularize vaccination. They make one sympathize with those who in order to minimize the reaction go in for "minimum-of-trauma" methods.

In the light of recent reports as to the failure of comparatively recent vaccination to protect, one can quite agree with Dr. Beaumont that the old idea that vaccination would protect for seven years should be frankly abandoned. My own preference, at least for persons in this country, is "little and often," and for medical practitioners or anyone who may have to deal with smallpox—i.e., hospital and sanitary staffs—it would probably be a good plan to make revaccination an annual event. There would then be practically no reaction and we should see an end to doctors, sanitary inspectors, and nurses contracting the disease and sometimes even dying from it. The general population could very well be left unvaccinated unless they were actual contacts. The great danger of outbreaks of virulent smallpox due to "missed" cases in vaccinated subjects would then largely cease to exist.—I am, etc.,

Leicester.

C. KILLICK MILLARD.

Epidemic Gastroenteritis Successfully Treated with Mepacrine

SIR.—Your annotation entitled "The Miasm of Marasmus" in the issue of Oct. 5, in which you draw attention to "epidemics of gastroenteritis of obscure origin," prompts me to record my own experience in this field.

An epidemic of gastroenteritis occurred in the midwifery department of this hospital and affected the majority of the staff and a large proportion of the patients. As unexplained epidemics of gastroenteritis have occurred at many hospitals recently, particularly in the midwifery departments (in some of which it has almost become endemic), the successful treatment with mepacrine of cases in this epidemic and the ultimate stoppage of the epidemic by this means is here described, with the suggestion that this drug may be tried in similar epidemics elsewhere when other means have failed. A remarkable feature was that it was almost entirely confined to the staff and patients of the midwifery block.

The first case occurred on June 6, 1946, and the incident followed the usual epidemic rise and fall during the subsequent 5 weeks, except that instead of falling to zero, as would have occurred in a closed community, a steady trickle of fresh cases continued as new patients were admitted and as additions were made to the staff. In the midwifery block 24 of a total of 27 nurses were affected, and the total number affected, including also medical officers, domestic staff, and patients, was 52. On the general side of the hospital only 3 nurses of a total of 125 were affected.

Clinically the onset was abrupt. The stools were water often containing comparatively little faecal matter at first, 1 to 25 being passed in the first 24 hours. There was never an mucus or blood. Vomiting occurred in two-thirds of the case. Colicky pains occurred in all cases, especially before defaecation. Only two cases were pyrexial, but several were prostrated by the continual stomach and bowel activity and consequent dehydration. A peculiar feature of most cases was apparent recovery lasting 24–36 hours followed by relapse. Recovery lasting 48 hours was maintained. No patient was seriously ill with the exception of two nurses and two undersized new born infants. Frequent liquid stools were passed for 5–7 days regardless of treatment, until mepacrine was tried. The interval between admission to the wards and onset of symptoms varied from 2 to 11 days, and averaged 8 days. Examination of stools disclosed no pathogenic bacteria.

Drugs administered were sulphaguanidine or succinyl sulphathiazole 12 g. daily, 10 min. (0.6 ml.) each of tinct. bella donnae and tinct. opii t.d.s., and kaolin. These were quite without effect. No *Giardia lamblia* were seen during the main epidemic, but one specimen contained what may have been degenerate cysts. On the strength of this, but also because the treatment had hitherto been ineffective, all subsequent cases were given mepacrine 0.1 g. t.d.s. for five days. On this treatment there was prompt recovery, normal stools being passed within 18 hours. Vomiting did not appear to interfere with its action, and this symptom ceased with the treatment. The success achieved with this drug supported the theory of a protozoal origin, although no protozoa were for certain seen.

While an effective form of treatment had been found, fresh cases continued to occur at the rate of about four per week. In particular new additions to the staff of the midwifery block fell victims. The number of nurses off sick at any one time numbered two to four. In the stools of one solitary case after the main epidemic *Giardia lamblia* and its cysts were found. In view of the occasional presence of this organism in diarrhoeic stools, to which it is not causally related, one would not be justified in attributing to it the cause of the epidemic. This unsatisfactory state continued for a further four weeks.

Owing to shortage of staff, nurses were reluctant to report sick and in fact usually did not do so for 1–2 days after the onset of symptoms, as they hoped that the latter would subside spontaneously. It was believed that the epidemic was being maintained by the presence of these ambulant cases. It was also suspected that the failure to grow a causal organism was in part due to a certain amount of self-medication with sulphonamides before reporting sick. Instructions were therefore issued to all staff (1) to report immediately any gastrointestinal symptoms, (2) to send as fresh a specimen as possible to the laboratory, (3) to take no drugs until ordered to do so by a medical officer. These instructions were followed, I believe, conscientiously without any drop in the incidence of cases. As stated, cases continued to occur for a further 4 weeks, and their number included some breast-fed infants.

All persons concerned took the usual hygienic measures to avoid cross-infection. This raises speculation on the possibility of air-borne transference of the infective agent. Feeling sure that one or more carriers were responsible, mepacrine (0.1 g.) once a day for five days was issued to all staff visiting the department regularly (nurses, domestics, and medical officers) and to all the mothers. Since then there have been no further cases.

The information given above can be summarized thus: an epidemic of gastroenteritis affecting staff and patients of the maternity wards of a general hospital is described. Features were: (1) The epidemic was practically confined to the maternity block, although the staff mixed freely with staff from other parts of the hospital; (2) onset was sudden, stools

ere watery and contained no blood or mucus, and vomiting occurred in two-thirds of the cases; (3) no causal organism as for certain isolated; (4) there was no response to sulphuanidine or succinyl sulphathiazole; (5) prompt cure occurred with mepacrine; (6) the epidemic continued in spite of the usual precautionary measures until prophylactic mepacrine was issued to all persons in the midwifery block, when it promptly ceased.—I am, etc.,

St. Giles's Hospital (L.C.C.).

Haemolytic Icterus due to Rh Factor

SIR,—I append brief notes of a case of haemolytic icterus due to Rh factor. The unusual family history makes it a case of some interest and one which may be useful to record.

Mrs. B., P.P. 7, aged 33.

Obstetric History.

1929. Girl.	Birth weight	9½ lb. (4.2 kg.)
1932. Boy.	" "	8½ " (3.8 kg.)
1935. Boy.	" "	8½ " (3.8 kg.)
1938. Boy.	" "	6 " (2.7 kg.)
1940. Boy.	Twins {	6 " (2.7 kg.)
Girl.		5½ " (2.4 kg.)
1943. Boy.	" "	6 " (2.7 kg.)
1944. Girl.	" "	5 " (2.2 kg.)

There have been no miscarriages or stillbirths. No child has had jaundice at birth. All are alive and well except the girl twin, who died at 4 days; she was not jaundiced, but cause of death unknown.

In 1945 she became pregnant again. Antenatal period normal. On Sept. 4, 1946, she was delivered by a midwife at home of a normal full-term female child, weight 7½ lb. (3.3 kg.). Labour normal and lasted 72 hours. The child breathed and cried spontaneously. It was noticed to be a little yellow. On Sept. 8 I was called to see the child as jaundice was not subsiding. On examination the child cried and sucked vigorously. The skin was a pale lemon yellow. Mucous membranes pale. No signs of infection. Liver easily palpable. Spleen not felt.

The case looked like a haemolytic icterus, but the history seemed to make it unlikely that Rh factor was concerned (all children are by the same father). However, blood samples were sent for examination. *Result*.—Mother, Group A, Rh-negative, weak Rhesus agglutinins and incomplete antibodies present; Father, Group O, Rh-positive.

Family history, as far as can be ascertained, shows that one sister of the mother has given birth to a child that died at the age of four days with jaundice.—I am, etc.,

London, E.13.

P. G. S. KENNEDY.

New Blood

SIR,—I enjoyed your amusing little annotation entitled "New Blood." I had always been told that the British moved slowly, but had not realized that it might take one of their editors exactly nine months to deliver good wishes to an aspiring editor of a new journal. Nevertheless, I appreciate these thoughts however belated and have taken to heart the advice which is so freely given. Let us hope that the readers of *Blood* will not always have to eat caviare as the editorial writer fears, but will occasionally have the opportunity to participate in a more solid and nutritious diet. As a matter of fact, had the anonymous editor taken the trouble to inspect, even casually, the March, April, and July issues, he might have seen some good "solid meat." For example, there was an article by C. J. Watson dealing with haemoglobin and its derivatives, some observations by Carl Moore on the use of intravenous iron, notes on the presence of erythroblastosis foetalis in the first-born by Philip Levine, three articles and an editorial dealing with certain abnormal splenic effects, three articles on problems of blood coagulation, and three articles dealing with some rather serious complications of infectious mononucleosis. The editorial goes on to say that "the most important causes of anaemia are malnutrition, malaria, and hookworm disease, none of which is likely to be adequately considered in a journal of haematology. . . ." The July issue has a 38-page review of the present status of folic acid by L. J. Berry and Tom D. Spies; I think this will be a classic article on the subject for a long time. A 60-page monograph on the dietary factors concerned in haematopoiesis from Wintrobe's clinic is shortly to appear. Relative to malaria and hookworm disease, the July issue contained

an interesting article from Palestine by de Vries on the excretion of urobilinogen in the stools and urine during malarial infection, and the December issue will have an article from the Philippines on hookworm anaemia, with particular reference to aplastic anaemia. The rather startling statement is made that "The great advances in haematology have not been made by professed haematologists, and future advances would be unlikely to be published in a journal of haematology. . . ." The first part of this sentence hardly deserves comment, but the second phrase is subject to critical appraisal. *Blood* has already had between its covers some real advances dealing with hypersplenic effects, with the use of penicillin in agranulocytosis, the use of anti-haemophilic plasma globulin in haemophilia, the use of radioactive phosphorus in polycythaemia and the use of thymine as an anti-anaemic substance.

Another remarkable and rather "precious" statement is that "Haematology is not a unified subject or discipline in the same sense as neurology and cardiology, and it is too limited and depressing a section of clinical medicine and pathology to constitute a whole-time specialty. . . ." It is possible that once a specialty becomes "unified" like cardiology or neurology, there can be no further advance in it. Haematology has many facets making it a field of exceeding interest, and there is no reason why the haematologist should not concern himself with the nutritional aspects of anaemia, the sarcomatous aspects of leukaemia and the immunologic aspects of haemolytic anaemia. One doesn't have to be an immunologist to know something about haemolysins and agglutinins. The chief fascination of clinical investigation is that it leads one from the patient into any and all kinds of interesting by-ways whether of chemistry, immunology, or pharmacology. We read that haematology is first, "not unified," again it is "too limited," and finally it is "depressing." It is true that acute leukaemia is a depressing disease, but it is certainly exciting to see the dramatic results of splenectomy in idiopathic thrombocytopenic purpura, and in many cases of haemolytic anaemia and splenic neutropenia. It is by no means depressing to see the startling effects of a few milligrams of folic acid in pernicious anaemia and sprue, nor is it saddening to note the complete relief of symptoms in polycythaemia by use of systematic venesections and the cure of erythroblastosis foetalis by an appropriate transfusion technique. I think we should also feel a little encouraged by the recent advances in the treatment of haemophilia, to say nothing of the remarkable results obtained in shock with transfusions of blood and blood substitutes. I think, however, that it is depressing to note such limited knowledge by at least one of our British cousins as to what is haematology and what it is accomplishing. We didn't think it was a limited field when we started the journal *Blood*. I must admit that the word "haematology" might seem to connote a rather narrow field, perhaps excluding such things as immune bodies, plasma fractions, and nutritional disturbances. It was for this reason that Dr. George R. Minot, our consulting editor, insisted on the use of the simple word *Blood*; in line with the titles of the British Journals *Brain* and *Heart*.

Perhaps I have spent too much time and space in reply to a minor editorial dealing with the launching of a new specialty journal. It has given me an opportunity, however, to air my views and for this I am grateful. May "New Blood" constantly permeate even our older journals, for which we have such outstanding affection and respect.—I am, etc.,

Boston, U.S.A.

WILLIAM DANESHEK.

SIR,—I would agree with the writer of "New Blood" (Sept. 7, p. 335) that specialized journals devoted to haematology are likely to be "caviare," not "good solid meat"; but I would assert that the same is true of neurological, cardiological, and all other special periodicals. But what matter if it be so? The specialist is interested in the minutiae of his subject and looks to the general medical press, not to his special journals, for the occasional publication of great advances which have a significance far transcending his specialty. The real interest, at least to me, of the article "New Blood" was the picture it presented of haematology as being "too limited and too depressing a section of clinical medicine and pathology to constitute a whole-time specialty." The statement would probably be true if it read "clinical medicine or pathology," but, if it implies that there is not enough in the clinical and pathological aspects of

haematology to constitute a whole-time specialty, I would join issue with the writer.

Glancing through my notes of the past three months, I see that the following cases (among others) have been referred to me by practitioners: patients with symptoms of anaemia, generalized pruritus, enlarged glands, splenomegaly, erythrodermia. In the first group there have been examples of pernicious anaemia, idiopathic hypochromic anaemia, carcinoma of the stomach, aortic incompetence, chronic plumbism, various types of leukaemia, and other maladies. The cases of glandular enlargement have included leukaemia, Hodgkin's disease, tuberculosis, secondary syphilis, pediculosis, and secondary carcinoma, while the splenomegalies have varied from chronic myeloid leukaemia to kala-azar. That the purely laboratory aspect of these diseases would be limited and depressing is true; that the purely clinical investigation of them might be so is probable; but who can assert that a specialty which enables one to deal with the clinical, laboratory, and therapeutic aspects of so varied a collection of maladies is limited and depressing? Your writer says that "haematology is not a unified subject," and, although he was intending disrespect to the subject, I would assert that it is this very fact that makes haematology one of the widest and most interesting of specialties. Equally, his indisputably true statement that scientists investigating different aspects of haematology do not speak the same language is one of the strongest reasons for the existence of physicians whose main interest is in haematology, and who can act as liaison officers between the academically minded scientist and the patient who needs skilled attention. I would, of course, agree with the writer that the proper exponent of haematology is the clinician, though the pathologist, the geneticist, and the transfusion officer may be the best exponents of small branches of the vast subject.—I am, etc.,

London, W.1.

A. PINEY.

History of the Hogben Test

SIR,—In describing (*B.M.J.*, Sept. 7, p. 328) his improved method of concentrating urine for pregnancy diagnosis by recourse to *Xenopus* as a test animal, Mr. Milton's brief account of the history of the test might well convey an erroneous impression of the part played directly and indirectly by the writer in its discovery. He states: "Hogben (1930) demonstrated that if the animal was injected with anterior pituitary preparations ovulation and oviposition could be induced. This fact was subsequently made use of by Bellerby (1934) and by Shapiro and Zwarenstein who independently suggested that the phenomenon could be utilized as a pregnancy test" (italics inserted).

In 1929 I completed experiments which showed that *Xenopus* responds by ovulation at any time of the year to the gonadotrophic hormone of the anterior lobe of the pituitary, and that the ovary undergoes involution after hypophysectomy. As stated by Mr. Milton, a preliminary note (*Trans. roy. Soc., S. Afr.*) recorded this discovery in 1930. A later publication (Hogben, Charles, and Slome, 1931) based on more extensively planned experiments of the same sort, also including a record of others dealing with the effect of hypophysectomy on the blood calcium level and the relation of light to the pituitary control of the ovary, appeared in the *Journal of Experimental Biology*. At that time, the identity of the gonadotrophic substance in the urine of pregnant women and the anterior lobe hormone with the same action was generally accepted. I therefore made arrangements with a South African obstetrician to use *Xenopus* in order to probe its relation to the pituitary autacoids from a new angle. Dr. Zwarenstein was then taking a course of postgraduate study in my department, in which he learned my technique (Hogben, *Quart. J. exp. Physiol.*, 1923) of hypophysectomy, and with my encouragement undertook further work on the relation of pituitary and ovarian function to blood Ca and K levels, when I relinquished my chair in South Africa.

On my return to England in 1930 I made contact with Prof. Crew, who had started a pregnancy diagnosis unit, pointed out the advantages of a test animal which ovulates visibly, and can be used repeatedly, intimated that it might be long before I should have a laboratory fully equipped to resume such work, expressed the hope that he would follow it up, and sent him loads from the small stock I had brought back. By 1932, when

Dr. Bellerby and Dr. Landgrebe had joined my staff in London, Zwarenstein reported to me the virtual impossibility of maintaining ovarian activity of *Xenopus* under laboratory conditions; and subsequently published in the *Journal of Experimental Biology* (Shapiro and Zwarenstein, 1933) account of what he called the captivity effect, implicitly overturning my expressed view that *Xenopus* is peculiarly fit for gonadotrophic assay. At first Crew's colleagues themselves experienced similar difficulties; and, since a test based on use of freshly caught animals whose natural habitat is highly localized could have no international value for medicine recognized that extensive use of *Xenopus* for gonadotrophic assay must await fuller elucidation of conditions for maintaining its reproductive activity in the laboratory.

Working with me in London, Bellerby and Landgrebe therefore undertook at my suggestion a series of investigations (Bellerby, 1933; Alexander and Bellerby, 1935; Bellerby and Hogben, 1938; Bellerby, 1938; Landgrebe, 1939), severally published in the *Biochemical Journal* and *Journal of Experimental Biology*, to vindicate the use of an amphibian test animal studying: (a) the effect of diet, overcrowding, light, etc., the fertility of *Xenopus*; (b) the possibility of breeding *Xenopus* in the laboratory without recourse to importing new stock; (c) the action of pituitary extracts on the British common frog. *Pari passu* Bellerby (1932-3) carried out a series of tests showing that *Xenopus* responds to the gonadotrophic substance in the urine of pregnant women. For the reason stated above I discouraged early publication of our results as of mere academic interest until we could also announce a fool-proof regimen of animal husbandry. Meanwhile I had privately communicated to Zwarenstein and to his junior colleague Shapiro both about to visit Britain, the fact that my regimen did in fact ensure persistent ovarian activity of imported stocks, and that their so-called captivity effect was due to defective care of their animals. I also invited them to see my new set-up. Accordingly, Zwarenstein and Shapiro enjoyed the hospitality of my laboratory during their visit to London in 1933. We then demonstrated to them both the results of our pregnancy tests and the success of our own method of maintaining ovarian function of *Xenopus* over an indefinite period of time in an artificial habitat.

On returning to South Africa, Zwarenstein and Shapiro made similar tests on *Xenopus* freshly caught from local ponds, and issued a note (*Trans. roy. Soc., S. Afr.*) recording their successful outcome shortly before a preliminary announcement of work in my laboratory (Bellerby, 1934) appeared in *Nature*. For sufficient reason I made no unfavourable comment on this. At that time Zwarenstein and Shapiro had not yet withdrawn their previous assertions about the so-called captivity effect, in conflict with my original claims with reference to the peculiar suitability of *Xenopus* for assay of gonadotrophic substances. Indeed, the practicability of the test was not finally vindicated until Landgrebe (1939) completed a long series of experiments under my direction setting forth the conditions which ensure that *Xenopus* will continue to respond to gonadotrophic preparations in a laboratory environment. In fairness to two of my colleagues I must add this. By luck or good management I had equipped my Cape Town laboratory with what proved to be a satisfactory lay-out for prolonged survival experiments for earlier work (Hogben and Slome) on the pituitary *vis à vis* the chromatic function. Though publication of the captivity effect of Zwarenstein and Shapiro materially delayed preliminary announcement of pregnancy tests, it had a salutary result. Certainly other workers would have experienced difficulties which eluded my own system of laboratory care; and the test itself could vindicate its credentials only after explicit clarification of the essential conditions of artificial culture in the hands of others who did not start with the advantage of my own intensive experience of work on *Xenopus*.

Presumably it was for reasons here given that Crew, himself acquainted from the start with the inside history of difficulties besetting the final accomplishment of a project I nursed from the date of the parent discovery in 1929, suggested the association of my own name with the *Xenopus* method of pregnancy diagnosis as those of Zondek and Aschheim and of Friedmann were already associated respectively with methods relying on the mouse and the rabbit as test animals.—I am, etc.,

PAIN is relieved, swelling controlled and hæmatoma
 formation prevented by the use of an 'Elastoplast'
 Bandage applied over the joint, muscle or ligament.
 Early application permits the patient to use the injured
 part and shortens the period of incapacity.

In the 'Elastoplast' Bandage the combination of the
 particular adhesive spread, with the remarkable stretch
 and regain properties of the woven fabric, together
 provide the required degree of compression and grip.

Vitamins in Obstetrics

For more than 18 years Vitamins Ltd., have been working on nutritional subjects. During that time, dramatic advances have been made in the recognition of deficiency conditions and diseases, and in the appropriate uses of vitamin therapy.

In pregnancy, when dietary requirements are raised, it is important to take prophylactic measures against the development of latent deficiencies.

Condition	Indications	Therapeutic Agents
STERILITY Sub-fertility Habitual or threatened miscarriage	These conditions when not traceable to structural or endocrine abnormalities may be associated with a deficiency of vitamin E.	FERTILOL (Wheat germ oil stabilised and standardised) 1 to 3, 3 mg. caps. daily. BEMAX contains vitamin E (8 mg. per oz.) and other factors which may be important.
PREGNANCY TOXAEMIAS	May arise when the extra demands of pregnancy are not met in the diet.	PREGNAVITE TABLETS . A comprehensive dietary supplement designed to meet the pregnancy requirements of the important vitamins and minerals.
HYPEREMESIS GRAVIDARUM	May be one sign of the above.	VITAMIN B₁ (Pyridoxin), Vitamins Ltd., 10 to 20 mg. thrice daily. VITAMIN B₂ (Aneurin hydrochloride), Vitamins Ltd., 10 mg. or more daily.
OEDEMA	As in beri-beri and congestive failure may in some cases be associated with vitamin B ₁ deficiency.	VITAMIN B₁ (Aneurin hydrochloride), Vitamins Ltd., 3 to 10 mg. daily.
HAEMORRHAGE in the new-born	To raise prothrombin levels in the first days of the infant's life.	VITAMIN K , Vitamins Ltd., 10 mg. tablets, one daily to the mother or the contents of 1 Ampoule to the infant.

NEW CARS

-can we help?

For the last twenty years our work has consisted of advising the medical profession in regard to their motoring, which is of course of vital importance to them.

We are contracting agents for practically every popular make of British car and are therefore able to give a truly unprejudiced opinion.

We have a special scheme available for ex-Servicemen returning to general practice who would be very seriously handicapped without some form of transport.

Our special Hire Purchase terms, financed by ourselves, are easily adaptable to suit the individual requirements of our customers.

Service facilities are gradually returning to our pre-war standard of efficiency.

G. J. SHAFFER & CO., LTD.

A
JEYES'
PRODUCT

STREPH

* THE COMPLETE ANTISEPTIC

A SUMMARY
OF THE
ADVANTAGES
OF
STREPH

- (1) Non-selective.
- (2) Activity is maintained in the presence of proteins.
- (3) Non-necrotic, non-toxic, non-staining.
- (4) Clear solutions with water, normal saline, and alcohol.
- (5) Powerful deodorant.
- (6) Almost odourless.
- (7) Powerful detergent and compatible with soap.
- (8) STREPH is approximately three times as effective as Liq. Chloroxylenolis or lysol.

For these reasons STREPH is the ideal antiseptic for medical, surgical and obstetrical use.

Reiter's Disease

SIR,—Nearly all the previous writers on this syndrome agree that the condition described by Fl.-Lieut. W. P. U. Jackson Aug. 10, p. 197) and Dr. F. Wrigley (p. 199), is not of gonococcal origin, but a complication of bacillary dysentery. That here are other aetiological factors responsible for this syndrome I have not the slightest doubt. In the autumn of 1943 many Service personnel were admitted to a military hospital in the south of England with haematuria accompanied by pyrexia and toxæmia. The haematuria occurred at the end of micturition. None of those affected had been in the Tropics, and there was no history of dysentery or venereal infection. The urine contained many pus cells, but was sterile to ordinary methods of culture. Cystoscopy revealed an oedematous and hyperæmic trigone. The condition was labelled "basal cystitis." The macroscopic terminal haematuria lasted for three or four days, and was followed in 30 to 40% of cases by a polyarthritis and sterile conjunctivitis at about the tenth day of the disease. The joints involved were chiefly the knees, and occasionally the ankles and elbows. Culture of the aspirated fluid was sterile. The condition was thought to be due to a virus.

Again, during my stay in northern Nigeria from 1944-6, this syndrome of polyarthritis and sterile conjunctivitis was very commonly encountered among native troops in the acute stages of gonococcal urethritis. In no instance did it appear during the first attack of gonorrhoea and invariably a history of four or five previous attacks obtained. Its appearance coincided with the onset of the urethritis, which was shown to be gonococcal in origin. Sometimes one would see a sterile conjunctivitis without polyarthritis in the acute stage. Further attacks of gonorrhoea in the patients who had previously exhibited this syndrome resulted in an even more intense associated polyarthritis and conjunctivitis during the acute stage of the urethritis. In view of the appearance of this syndrome after many known attacks of gonorrhoea, and the increase in its severity during subsequent attacks, it was considered to be an allergic manifestation of the gonococcal organism. Obviously then many conditions can give rise to this combination of sterile conjunctivitis and polyarthritis. It occurs as a complication of bacillary dysentery, non-specific urethritis, "basal cystitis" (to which I have referred), and gonococcal urethritis. It is interesting to note that in the last three conditions there is an infection of the lower urinary tract.—I am, etc.,

Watford.

JOSEPH DENFIELD.

Ascariasis and Pulmonary Infiltrations

SIR,—Dr. D. Landsborough in the comments on his case of "Ascariasis Causing Acute Intestinal Obstruction" (Sept. 28, p. 461) remarks: "With such a heavy infestation with roundworms it is curious that there was no history suggesting 'ascaris pneumonia,' nor of toxic manifestations such as urticaria."

Of individuals with ascariasis it is surely only those who are hypersensitive (allergic) towards ascariasis who develop pulmonary infiltrations of the Loeffler type (or other allergic manifestations), and most persons are not hypersensitive (see the discussion on the subject by Spühler and Kartagener (1944), *Schweiz. med. Wschr.*, 74, 1145).—I am, etc.,

London, W.I.

F. PARKES WEBER.

Health Service Bill

SIR,—I do not agree with Dr. R. W. Graham-Campbell's statement (Sept. 28, p. 474) that I treated Dr. Dain unfairly in regard to his statement that "the right of entry of every doctor into the Service is not conceded as it was in the case of the N.H.I." The Health Bill says that every practitioner, if he wishes, shall be entitled to be included in the list. The N.H.I. regulations state that every practitioner can join the Service under the terms of service offered by the Committee, and approved by the Minister, subject to such alterations as may from time to time be made by the Minister. There can be no such thing as an absolute right to join either Service: it must in practice always be conditional. Every citizen has a right to enter a railway carriage and travel, but only if he accepts the rules and regulations of the railway company.

I feel sure that if the much abused "direction of doctors" is considered without prejudice it will be realized to be an ingenious scheme for the rational distribution of medical man-

power for the convenience of doctors, especially the younger men, and the benefit of the public. A general practitioner told me lately he wanted particularly to practise in a seaside town on the south coast, but could not get there on reasonable terms and had to go where "he jolly well could." Probably in actual practice the choice of locality will be much the same whatever the method adopted.—I am, etc.,

Westbury.

CHAS. E. S. FLEMING.

SIR,—We will shortly be asked to say whether or not we desire the B.M.A. to "attempt" to negotiate with the Ministry on the proposed Bill. Before answering an enthusiastic "yes" to this it would be well for everyone to consider that when once we do so we shall have more or less committed ourselves to an Act which many doctors object to for the following reasons.

(a) *Abolition of the right to buy or sell practices.*—It is ridiculous to say that when we buy practices we buy patients. It is simply the goodwill that is purchased, and the patient need not consult the doctor who buys the practice if he does not like him. It is up to the new doctor by his own skill and endeavour to attract and retain the patients, otherwise they will leave him in favour of another doctor. Are we to be paid for these practices on our death or retirement; or are we to continue to be able to retire when we wish and to sell to our successor? We shall certainly want the right of sale of practices under the new scheme.

The Minister states that the sale of practices is abhorrent to him, as it loads the young doctor with debt. Surely any young doctor with ordinary grit and determination to make good and an appreciation of things worked for and achieved would be willing, as we have been, to undertake the task, and if energetic and ordinarily careful should be able to clear off his debt within a reasonable time. I admit there is a tendency nowadays for the ordinary young doctor (and young people generally) to want things handed to them on a plate.

(b) *Negative direction.*—This I fear would soon become positive. It is an unpleasant prospect for many, to whom the right to choose the district in which they will work means much, if they are to be happy and do their best for their patients. Now that the war is over are we doctors to be singled out for this type of treatment?

(c) *Dismissal, if convicted of misdemeanour under the Service, without right of appeal to Court.*—Surely this savours of Nazism and dictatorship in its worst form and is intolerable to every doctor. A Government official has said, "Those who do not join the new Service can emigrate or retire"; and, "A doctor may be a good doctor, but if he does anything which causes him to come under the displeasure of the Minister he will be expelled even if he is a good doctor."

I consider that the terms offered may be attractive at first but will probably come down with a bang inside a year or two, leaving us helpless to protest should we have signed on the dotted line. What is the alternative if we don't join? The public has already given us a lead by their insistence (and I am speaking of insured persons particularly) in five cases out of ten on consulting a specialist and entering a hospital privately, and I do not think that we need be unduly apprehensive about their willingness to co-operate as private patients if the scheme is not worked.

Let us be united in our determination, as a great profession, to refuse to be the first guinea-pigs in the laboratory of this present Government. Let us remember that only as free men and women can either doctors or patients maintain not only our national life but our Empire in the important tasks which the stabilization of a lasting peace will require them to undertake in the years to come.—I am, etc.,

Burton-on-Trent.

J. R. SALMOND.

Legal and Medical "Insanity"

SIR,—Is it not time somebody turned the cold spray on the so-called McNaghten Rules, which have already received a cold douche from the medical point of view in the textbook of Henderson and Gillespie? In the first place, what is meant nowadays by the words *right* and *wrong*? These words may have been fairly well defined a hundred years ago, but to-day cover such overlapping fields as to be purposeless unless evidence is led as to their meaning. Secondly, is evidence that

an accused person of doubtful sanity is aware that the community at large knows his behaviour is wrong or unacceptable to them real evidence that he himself considers it to be wrong? Many an insane person wages war on the community with the most cunning deception while in the private world of their unconscious they are intensely imbued with the righteousness of their causes. Thirdly, is the patient's capacity to develop insight not a more important test? But even if it is, is insight an item which can become a court exhibit directly or even indirectly through expert witnesses? I doubt it. The diagnosis of its absence depends on *rapport* or that blending of mental relationship between examiner and examinee, which can be ruined by even a slight degree of hostility, real or imagined, on the part of the examiner. Is this not too highly technical a factor to be left to a jury even to decide a point of law?

The late Prof. L. Susan Stebbing in her book *Philosophy and the Physicists* has a chapter on "Human Freedom and Responsibility." In this she states: "The problem of free will does not present itself to plain men" (presumably of the type who become jurymen) "as a problem of analysis. Rather it presents itself as a problem of reconciliation. The reconciliation required is between (1) the fact of our intuition of freedom; (2) our beliefs with regard to the correct analysis of that intuition; (3) our beliefs concerning the nature of the conditions of moral responsibility; and (4) our beliefs with regard to the nature of the conditions of the physical world within which our actions have consequences." She then goes on to distinguish between "responsibility for" and "responsibility to." Now, it is obvious that few jurymen will embark on a process of elucidation such as this in forming their opinion. It is equally obvious that for most cases such an elucidation is not required. But an elucidation along a similar plan is required in diagnosing insanity. Later she states: "The justification of punishing lies in the conditions of the welfare of society. Sometimes it is expedient that one man should die for the people. This is the rule of expediency. Social authorities can adopt no other standard since they cannot know *what I am*; they can judge only of what they observe me do. That which I can be observed to do is a partial indication of what I am and of what I am becoming. But it is a partial indication only. It is dangerous to attribute to the powers that be—to the State—an insight into my nature."

Does this not contraindicate a rule-of-thumb method even if it is a good one?—I am, etc.,

Westell.

JOHN A. MCCLUSKIE.

SIR,—While it is impossible to dispute the correctness of the verdict in the Heath case one may perhaps give expression to a widely felt disquiet as to the moral value of the sentence. That it may be socially desirable that Heath should pay the penalty of his crime is perhaps beyond dispute, but is it right that he should? This man's history shows an almost lifelong inability to appreciate the feelings and interests of others: the trial has brought out his present affective indifference to the welfare of others in a very dramatic manner.

Once again we are brought up against the inadequacy of the McNaghten Rules when applied to cases of severe and prolonged psychopathy, and I personally had hoped that this case would result in some recognition of the need for some new approach to what is now recognized as a common type of psychiatric problem. Is it not foolish to wait until the psychopath has ruined several lives before attempting to deal with him, and then only by hanging? The recognition of the need for some form of indeterminate sentence is now accepted by a large number of those who have to deal with this type of personality. It is to be hoped that this case will bring this much-needed reform of our Penal Code before the public: such a procedure would lessen the chances of occurrence of such a tragedy as the present one.—I am, etc.,

Ryhope, Sunderland.

T. MARTIN CUTHBERT.

Pronunciation of Medical Words

SIR,—Referring to Dr. C. E. S. Harris's letter (Sept. 21, p. 442), may I ask a question? If once we begin to correct our pronunciation where are we to stop? Could we, for instance, hope to induce the whole medical profession to cease talking of the tibia and fibula and to say correctly tibia and fibula? So with the spelling of words: the customary asthenia should be astheneia. It would not be safe in every case to trust the *Oxford Dictionary*; we would have to rely on our Latin and Greek dictionaries.—I am, etc.,

Ventnor.

S. W. SUTTON.

Obituary

SIR WALTER LANGDON-BROWN, M.D., F.R.C.P.

The world of medicine and philosophy loses a distinguished figure by the death on Oct. 3 of Sir Walter Langdon-Brown, Emeritus Professor of Physic, University of Cambridge, and consulting physician, St. Bartholomew's Hospital. He was a great clinician, teacher, and humanist, a modern example of the scholar-physicians in the succession of Thomas Linacre. Langdon-Brown—he assumed "Langdon" as an additional surname by deed poll in 1935—sprang from Puritan stock, a heritage which he often gratefully acknowledged. The solid qualities of the Puritan character combined with his unusual mental endowments, forwardly directed gaze, and academic experience to make him the outstanding personality that he was. His father, the Rev. John Brown, D.D., a robust and militant Nonconformist, was the sixth direct successor of John Bunyan in the pastorate of Bunyan Meeting, Bedford, and author of the standard biography of Bunyan.

It was at Bedford on Aug. 13, 1870, that Walter Langdon-Brown was born. He went to Bedford School and then to St. John's, Cambridge, where he was Foundation Scholar and Hutchinson Research Student. He soon gave evidence of intellectual distinction, gaining first-class honours in both parts of the Natural Sciences Tripos. His time at Cambridge, to which he returned as Regius Professor more than forty years later, was one of great happiness. In his inaugural lecture as professor he spoke of his joy on returning to a place that had coloured the whole of his subsequent life. "I came here shy, awkward, and diffident, to meet with the most kindly encouragement. What germs of promise my teachers cunningly detected they assiduously cultivated. I return filled with the desire to repay something of the debt I owe to Cambridge." On one occasion he mentioned that while walking through Pump Court in the Temple he suddenly had a feeling of extraordinary happiness. Then he realized that the feeling was associated with the noise of a can being filled at a standpipe, and he knew that it recalled the noise his college servant used to make when filling the water-can for the bath that wakened him when he was a Cambridge undergraduate—"when to waken was to anticipate another delightful day."

His medical training was completed at St. Bartholomew's Hospital, where his name first appears in 1894 as winner of the senior open scholarship in biology and physiology. In the following year he was appointed, with the future Lord Horder, as assistant demonstrator in biology, in which capacity he read to the Abernethian Society at the hospital a critical and well-documented paper on the mechanism of phagocytosis. In 1896 he gave a second paper to the same body on the subject of the plague in England. In 1897 he qualified M.B., B.Ch., and was appointed house-physician to Samuel Gee, and at the same time became the second editor of *St. Bartholomew's Hospital Journal*. In 1901 he took the M.D. of Cambridge, gaining the Raymond Horton-Smith Prize for his thesis.

Some experience of military medicine followed. During the South African war he was appointed senior physician to the Imperial Yeomanry Hospital, Pretoria. Then came many happy and successful years in consulting practice in London. He joined the medical staff of his old hospital, first as assistant physician and then as full physician. His long participation in the teaching at Bart's is appreciated by many generations of students. In the ward round, the class-room, and the lecture theatre he was always lucid, able to present the subject in a manner adapted to the listener, and to communicate to others, especially the young, the subtleties of the art of medicine.

[Elliott and Fry, Ltd.]

ter in his career, when he was accustomed to give formal lectures and addresses to various bodies, those who heard him noted after him, so great was the compression of his talk. Classical allusion, epigrams, satire, and wise and penetrating observations with a side-glance at current events followed one another so quickly that the audience at the end felt they had been witnessing an unusually brilliant pyrotechnic display. Not at all there was anything showy about him: it was the urgency of his thought, clothing itself in eager words. But in his clinical teaching he never left his students bewildered. His benevolence, the range and receptivity of his mind, his appreciation of the student's point of view, his aptness in illustration, his mental vigour and alertness, which contrasted with his massive physical presence—all these things made him a teacher who will be long remembered in that home of great teachers, the school of Abernethy.

Sir Walter Langdon-Brown's interest in medicine extended over two great fields, both of them at the time insufficiently cultivated. The first was therapeutics and pharmacology. At a time when therapeutics was under a cloud he insisted upon the placing of treatment on a sound clinical basis. He once remarked that it was curious that the most materialistic age in history should have been the most sceptical in the use of drugs. When someone asked him how he could imagine that 5 gr. of a drug could have any effect on the whole body he replied that the body itself worked in fractions of a milligram. The second field in which he interested himself more and more in later years was the relation of the new psychology to clinical medicine. This was the subject of his last lecture as a member of the active teaching staff of Bart's in 1930, when he retired on reaching the age limit and became consulting physician to the hospital. He believed the province of medicine to be terminous with life, and that nothing that threw light on life was alien to medicine. No general physician did more to keep the whole patient "ever before the mind of student and practitioner." Langdon-Brown was a prominent member and chairman of the Society of Individual Psychology and made many important contributions to that and other bodies on psychological subjects. He presided over a committee on post-graduate training in psychological medicine whose report appeared in 1943.

Other appointments he held were those of physician and later on consulting physician to the Metropolitan Hospital and principal medical officer to the Provident Mutual Life Assurance Company. At the Royal College of Physicians, of which he became a Fellow in 1908, he had been Croonian Lecturer and Harveian Orator. In 1934 he was appointed Senior Censor. He examined in medicine for the Universities of Cambridge and Sheffield and the National University of Ireland. During the European war, in 1915, he carried out some useful work on war nephritis for the Medical Research Council. From 1932 to 1937 he was a member of the General Medical Council, representing the University of Cambridge. In 1934 when the British Medical Association met at Bournemouth he was President of the Section of Medicine. In the Royal Society of Medicine he was in turn President of the Sections of Urology, of Therapeutics and Pharmacology, and of the History of Medicine. He was an Honorary Fellow of the Hunterian Society and a Corresponding Fellow of the Harveian Society.

In 1932 came his appointment to the Regius Chair at Cambridge. In a letter to a friend, written at that time, he said, in response to congratulations: "I do feel that it is a good thing that the Regius Professorship should still be regarded as a clinical post. I hope that my long experience as a teacher of physiology will enable me to act as a liaison officer as it were between those engaged in the preliminary work at Cambridge and the clinical teachers at the hospitals. There is good work to be done in bridging that gap, and I hope I may be able to do it." His inaugural lecture was on English Medicine and the Cambridge School. He held the chair until 1935, and his long and happy connexion with Cambridge was continued on his election in that year as Fellow of Corpus Christi College.

In literary and scientific circles both inside and outside medicine Langdon-Brown's reputation as a philosophical thinker and writer stood high. In *Thus We Are Men* he discussed in some engaging chapters the problems of life in relation to philosophy and psychology and revealed himself as

a profound student of human nature. In the same volume he also endeavoured to trace the evolution of the religious impulse; probably he satisfied neither the orthodox nor their opposites, but he wrote, he said, in order to clarify his own impressions for himself. He had a happy turn for the telling phrase. Writings and lectures of his bore such titles as "We have reason to think," "Some gods and their makers," "New pains for old," "The style of life," "Just nerves," "On getting the rash out," and "Dr. Jekyll diagnoses Mr. Hyde," which last was the title of his Cavendish lecture to the West London Medico-Chirurgical Society. He was a frequent lecturer to the British Institute of Philosophy and to the Society for Mental Hygiene, and in his discourses he applied the principles of mental hygiene to sociology and to the political situation in an original and characteristically forthright way. His special interest was in seventeenth-century literature, an interest awakened in the first place by his Puritan upbringing. But his studies ranged over the whole field of culture, classical, mediæval, and modern. Some members of the profession will recall how, just before the war in 1939, he was one of a party chiefly of medical men who went on a cruise to the highlands and islands of Greece, including visits to Epidaurus and Cos, and gave a lecture there on Greek influence on medicine. One of the great influences in his mature life was Sir William Osler, the first meeting with whom, he said, he would never forget, so magnetic was the effect of Osler's personality. He wrote a biographical note for the republication of Osler's addresses in 1939. While he had many intellectual interests his first love was always for medicine, and he turned to art and literature only for illustrations and parallels. His medical writings included *Physiological Principles in Treatment*, which ran to seven editions, *The Sympathetic Nervous System in Disease*, and *The Endocrines in General Medicine*. He was also joint editor of the *Practical Encyclopaedia of Medical Treatment*, and contributed many articles and reviews to this *Journal*.

He was knighted in 1934, and among the other honours he received were the Hon. D.Sc. of Oxford, conferred in 1936 when the British Medical Association held its Annual Meeting there, and the Hon. LL.D. of the National University of Ireland and of Dalhousie University, Halifax, Nova Scotia. His marriage in 1931 to Miss Freda Hurry brought him great happiness. Lady Langdon-Brown was his constant companion, a friend to his friends, and (as he often acknowledged) an unfailing source of inspiration.

Dr. S. L. SIMPSON writes: The death of Sir Walter Langdon-Brown is a great loss to medicine, and especially to endocrinology, which owes so much to his creative vision and progressive ideas. Among clinicians he will always be regarded as the founder of modern clinical endocrinology in this country. His breadth of outlook and his capacity for keeping contact with the most recent advances in all departments was an outstanding manifestation of his exceptional intellect and scientific enthusiasm. He was the moving spirit in the initiation of the Section of Endocrinology at the Royal Society of Medicine this year, and his inaugural address on the "Birth of Modern Endocrinology" was characteristically invigorating and creative, although he himself was at the time too ill to be able to read his paper. His knowledge of psychology and of humanity was as fundamental as his knowledge of endocrinology. I had the privilege of knowing the late Sir Walter for some twenty years, during the last ten of which I shared his personal friendship and actively collaborated with him in endocrine literature. To those who knew him well, his great humanity, understanding, and capacity for friendship were outstanding qualities which made him beloved. He will be especially missed by his friends and all workers in the field of endocrinology throughout the world.

STANLEY WYARD, M.D., F.R.C.P.

Dr. Stanley Wyard, physician to the Cancer Hospital, the Victoria Hospital for Children, and the Princess Beatrice Hospital, who died on Sept. 29, was the son of the late Rev. G. L. Wyard, of Bournemouth, and was born in December, 1887. He was educated privately, at University College, Cardiff, and at University College Hospital, London. After qualification in 1909 he was house-surgeon and house-physician at the West London Hospital; he became M.D. Lond. in 1912 and F.R.C.P. in 1941. He served in the 1914-18 war in the R.A.M.C. After demobilization he specialized as a physician, particularly as paediatrician. His hospital appointments included those of physician to the Bolingbroke Hospital, the

Victoria Hospital for Children, the Belgrave Hospital for Children, the Princess Beatrice Hospital, and the Hounslow Hospital. Besides all this activity he was in turn medical registrar, assistant physician, and (on Lord Horder's resignation of that post) physician to the Royal Cancer Hospital; and it was perhaps here that his work and his talents obtained the completest recognition by his colleagues and contemporaries. Stanley Wyard was for a long time a member of the Departmental Committee on Cancer set up at the Ministry of Health. He had a thorough grounding in pathology before attaining distinction as a clinician; and the fruits of this were attested in the *Clinical Atlas of Blood Diseases* which he produced in conjunction with Dr. A. Piney; the sixth edition of this successful work was published in 1945. He also wrote a *Handbook of Diseases of the Stomach*.

The most loyal of colleagues and one of the most unassuming of men, Wyard was highly esteemed by his own profession and his patients; no trouble was too great for him to take on behalf of anyone who wanted his help, and everyone knew that his actions were completely unselfish. He married Constance Enid, daughter of the Rev. W. R. Lloyd, Llandarog, Carmarthenshire, who survives him with their one daughter. Dr. Wyard joined the British Medical Association, but had never taken office in the Marylebone Division or at headquarters.

H. R.

News has been received from Canberra of the death of Dr. FRANK MCCALLUM, Director-General of Health for the Commonwealth of Australia. A native of Melbourne and the son of the Rev. Dr. Alexander McCallum, he was born on May 26, 1890, and from Wesley College entered Melbourne University as a student of medicine. He graduated M.B., B.S. in 1917 and at once joined the Australian Army Medical Corps, serving with the Australian Imperial Forces in France. After the end of the war he became a member of the Commonwealth Quarantine Service and in 1927 was appointed director of the Division of Epidemiology in the Commonwealth Department of Health. Two years later he came to London as chief medical officer at Australia House, and after his return became director of quarantine and senior administrative medical officer. In May, 1945, he was appointed Director-General of Health. Dr. McCallum had been a member of the B.M.A. since 1922 and held the diploma in tropical medicine and hygiene of the English Conjoint Board.

Dr. JOHN HENRY DIXON PHELPS, who died at Great Malvern on Sept. 29, was born at Carlisle on Jan. 4, 1872, son of the Rev. John Phelps. He entered Queen's College, Oxford, in 1891 with an exhibition from Carlisle Grammar School and took his clinical course at St. George's Hospital. He obtained the English Conjoint diplomas in 1899 and held junior appointments at St. George's, graduating B.M., B.Ch. in 1903. After three years as resident medical officer at the British Hospital, Buenos Aires, he started in general practice in Yorkshire and for seventeen years held a number of public medical appointments in and near Richmond. During the 1914-18 war Dr. Phelps served at the Valetta Hospital, Malta, with the temporary rank of captain, R.A.M.C. He moved from Yorkshire in 1920 and became surgeon to the Malvern Hospital. He had been a member of the B.M.A. since 1907 and was also a member of the Medical Officers of Schools Association.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Roland Henry Winfield, M.B., B.Chir., who won the D.F.C. and the A.F.C. as an officer in the Medical Branch of the R.A.F., has been elected into Fellowship of St. John's College.

UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated:

M.D.—S. Cope, F. Debney, H. T. Hardy, T. Hardy, J. Hirst, K. K. Hussain, *E. Hyman, F. A. Lodge, K. G. Marshall, *J. D. Pickup, C. T. Roberts, *P. E. R. Tattersall, L. G. Topham, A. P. B. Waind, C. J. E. Wright.

CH.M.—D. B. Feather.
FINAL M.B., CH.B.—Part II: K. F. Wood (with second-class honours), R. H. P. Fernandez, R. S. Gillinson, Mary J. Hartley, F. Nicholl, J. P. Stuart. Part I: K. A. Exley, Marguerite J. Glover, Joan K. Hardy, R. I. M. Hepworth, A. T. Merson, W. S. Richardson, C. G. W. Sykes, K. H. Sykes, Freda Walton, W. Wintersgill.

* With distinction.

UNIVERSITY OF SHEFFIELD

The following candidates have been approved at the examination indicated:

M.D.—H. B. Stoner.
FINAL M.B., CH.B.—M. Redfern (with first-class honours and distinction in surgery), D. Dexter (with second-class honours).

UNIVERSITY OF ST. ANDREWS

The following appointments in the Medical School have been made by the University Court. *Lecturer in Pathology*: Dr. H. D. Reid. *Lecturer in Pharmacology*: Dr. Sydney A. Smith. *Lecturer in Tuberculosis*: Dr. D. G. McIntosh. *Lecturer in Midwifery and Gynaecology*: Dr. Alexander Buchan. *Assistant in Ophthalmology*: Dr. R. M. Mathers. *Assistants in Pathology*: Drs. J. H. Prain and William Walker.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Prof. Alexander Lipschutz, director of the Department of Experimental Medicine of the National Health Service of Chile, will give three lectures at the College, Lincoln's Inn Fields, on Monday, Oct. 28, Tuesday, Oct. 29, and Friday, Nov. 1, at 3.30 p.m. each day. His subjects are: the tumorigenic action of steroids and implication for the problem of cancer; the antitumorigenic action of steroids; and the steroid balance and the antitumoral autodefence. The lectures are open to medical practitioners and advanced students.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

A special meeting of the Council of the College was held on Sept. 27, and an ordinary meeting on Sept. 28, with the President Mr. Eardley Holland, in the chair.

The Honorary Fellowship of the College was conferred on Mr. Victor Bonney in recognition of his work as a gynaecologist.

The following were formally admitted to the Membership:

H. R. Arthur, S. J. Barr, B. E. Blair, Catherine I. Blyth, Joyce Burt, H. Burt, G. B. W. Fisher (in absentia), R. L. Hartley, D. Jeffries, Iola L. T. Jones, L. Lauste, Margaret Orford, H. C. Perry, D. L. Poddar, Esther M. Pollock, I. Scott-Carmichael, E. W. L. Thompson, T. G. E. White.

At the termination of the meeting on Sept. 28, Mr. William Gillis assumed the office of President, Sir William Fletcher Shaw as Mr. James M. Wyatt the offices of Vice-president, and Mr. Arthur A. Gemmell the office of Honorary Treasurer.

Medical Notes in Parliament

HEALTH SERVICE BILL

DEBATE IN THE HOUSE OF LORDS

The debate in the House of Lords on the Second Reading of the National Health Service Bill began on Tuesday, Oct. 8.

The LORD CHANCELLOR, moving the Second Reading of the National Health Service Bill, said the idea of a comprehensive health service was not new. It was not a product of mere post-war reconstruction and it was not the preserve of any one party. The principle underlying the Bill had been foreshadowed in the 1944 White Paper of the Coalition Government and was, he believed, uncontroversial. However, the present proposals were in many respects radically different from those put forward then.

Everyone was immensely proud of the medical services of this country and of the services that doctors had rendered to the health of the people. He was not an iconoclast, but on the other hand he did not doubt that they would have to alter—to modify and to expand—our existing institutions to make them fit in with the new ideal of a completely integrated medical service.

This was a Bill to introduce an altered, extended, and, in some respects, a new service. It was not a Bill to preserve ancient monuments.

Powers of the Minister

Speaking of the provisions for the mental health service, he said he did not conceal from the House that it was a mere temporary job. When time permitted they had to undertake a complete review of legislation dealing with mental health. The Minister of Health under the Bill had very great powers.

He was in the position of a commander-in-chief planning a campaign against a very dangerous enemy—the forces of disease and ill-health. He was, however, prevented from being what Lord Jowitt might term a "pocket Hitler."

Every single regulation he made must come before Parliament and either it must receive affirmative approval or it could be quashed by resolution of either House. Our hospital services, Lord Jowitt declared, had been developed in a haphazard way. The distribution of those services was quite irregular; they were overlapping in many respects. Our hospital system failed just because it was no system at all. Many hospitals were too small to justify independence. It was not the duty of anyone at the present time to see that the range of hospital services were fairly distributed among the people. That being so, no one, he thought, doubted the importance of rationalizing existing resources. "I don't believe," he continued, "that we can rely any longer on charity for the main hospital expenses. The day when you are going to run the services by dropping a shilling in my little tambourine are gone."

Full Freedom

The scheme involved no bureaucratic control from Whitehall. It did not involve a single additional Civil Servant. No doctor was to be compelled by direct or indirect pressure to join. He was to be in no way interfered with. He believed that by the machinery of the Bill they could achieve their object, which was to give full freedom and full scope and opportunity for professional skill. The technical training of the doctor, the dentist, or the nurse must be free from lay direction.

They must take care to see that the doctor was no worse off, and they must recruit the right type of man, one who would uphold the traditions of a very great profession. With regard to specialists, the Minister of Health was prepared to set up a committee to deal with the remuneration of specialists, and he thought that was the right course to pursue.

Referring to the shortage of dentists, he said that when people became better educated they would realize the tremendously important part which dentistry played in the health of the people and would insist on having a sufficient number of dentists. More people must be attracted into this great profession. At the moment, with the hopelessly inadequate number of dentists, all that could be done was to give some priority to those who should have dental care—for example, young children and expectant and nursing mothers.

The success of the scheme would depend on the day-to-day co-operation which the various people concerned showed in serving a great idea. He did not doubt that when they had thrashed this Bill out all sections and classes of the community would sink their differences in trying to press forward a great ideal for the betterment of the health of the people of this country.

Agreements Laid Aside

The EARL OF MUNSTER said he had hoped they would be able to discuss the Bill free from acute political controversy and in agreement so far as possible with every branch of the medical and health services. Unfortunately, agreements reached had been laid aside and certain provisions which they believed to be wholly detrimental to the future of the Service had been inserted in the Bill. There were wide differences and divergences between the proposals in the Bill and the scheme of the Coalition White Paper.

He asked the Government whether it was merely for political and doctrinaire reasons that the whole medical profession was to be saddled with a scheme they disliked and institutions which the public had generously supported for centuries were to be removed from their control. He felt that the removal of the hospital authorities from the London County Council—the largest hospital authority in the world—and other local authorities, and the encroachment by the Government on local affairs must tend to breed further apathy among the electors in local government. Under the Bill every citizen in the country would receive the same standard of service. A levelling process would be undertaken, and they all knew from experience that a levelling process must be downward.

With regard to the confiscation and use for other purposes of endowments, he said that for the Lord Chancellor to support

such a proposal must be unique in the law of trusteeship. It was the intention of the Opposition to move an amendment on the next stage of the Bill that between the passing of the Act and the appointed day any endowments which were received by any hospital should remain the property of that hospital and should not be transferred to the Hospital Endowment Fund. In that way they would ensure the co-operation of the British people for that unique organization.

So far as the medical service itself was concerned he could imagine nothing that would prejudice the working of the whole scheme more than imposing on the doctors a plan to which they were practically wholly opposed. It had never been made clear whether the scheme embodied in the Bill was the thin end of the wedge of State control. If the medical profession knew what the Government's intentions were their feelings towards the Bill might be better than they were. He could not help feeling how much better it would have been if the Minister had not ridden roughshod over all the institutions and persons who had to be brought into active partnership to make the scheme flourish and prosper.

Hospital Funds

The MARQUIS OF READING considered that the Bill moved a considerable step in the direction of increasing the general happiness of the people of this country. But he did not believe, however dynamic and superhuman a Minister of Health might be, that he could properly discharge the functions of housing and health at the same time. There should be separate Ministers. They should be closely in touch with each other's policy and should walk hand in hand. He confessed that the somewhat rapacious engulfing of the funds of hospitals was a considerable mouthful to swallow.

Only recently there came to his notice a case where a hospital was endowed by the local inhabitants as a memorial to one of their airmen killed in the war. Was it, he asked, the intention that that money should remain for the purpose for which it was subscribed or was it going to be swept into the omnivorous till of the Ministry of Health?

Health centres were an experiment and it was doubtful whether from the psychological point of view they would appeal to the public. He hoped, therefore, that the Government would proceed very slowly with their establishment. The Bill was a great conception but would need considerable amendment in Committee.

The ARCHBISHOP OF YORK, supporting the Bill with reservations, said the number of people who died from preventable causes showed that there was a call for a health campaign on a very large scale. He was afraid, however, that the scheme might to some extent undermine the independence of the medical profession.

He was anxious about the position of the voluntary hospitals and the effect of the scheme on local enthusiasm for these hospitals. He hoped that the local committees which had devoted so much time to the hospitals would not become mere vague shadows but would have real practical powers. He hoped also that the spiritual and religious ministrations which had been a feature of the voluntary hospitals would continue under the new scheme.

The Bill and the General Practitioner

Lord MORAN said with regard to the control of the hospitals there was no difference in the medical profession that if faced with the choice they would rather be under the Minister than the local authority. It was important he said to see that in the new scheme nothing was done to prevent the best men entering the medical profession.

He referred to an unfortunate dispute that had arisen at the eleventh hour between the Minister of Health and the general practitioners. He was perfectly certain that the Minister would meet their claims. It would be an absolute disaster if they began the Service and launched it with a very large section of the profession convinced that they had had a raw deal. If the Bill was going to work they had got to do something unusual. The Minister should put into the Service a small number of very experienced men who were leaders of the profession and persuade them to give their time to making the regions work. The Bill was a measure designed for the betterment of

the people in health and happiness. It was not the product of one party but of all parties over a number of years, and he hoped that when it became law the whole medical profession would unite to try to make it work.

Lord TEVIOR said they were faced with the fact that the state of the teeth of the people of this country was deplorable. There was no adequate service of inspection in the schools. At the present time there were about 15,000 dentists in the country, but quite a number were due to retire.

They must somehow or other encourage more to go into the profession. They must endeavour to raise the prestige and status of the dentist. It seemed to him that the Bill took away the patient-dentist relationship. The dental profession wished to make the scheme a success, but unless some of their objections were removed there would be a further decrease in recruitment for the profession and dentists would carry on outside the scheme. He hoped therefore the Government would do all they could to make the conditions of service under the Bill as attractive as possible. The position of dentists was far worse than that of doctors.

The debate continued.

Medical News

The prize distribution at Charing Cross Hospital Medical School will be made by Viscountess Addison to-day, Friday, Oct. 11, at 3.45 p.m., and Viscount Addison, M.D., F.R.C.S., will give the inaugural address in the Council Room of the Hospital.

The first dinner-meeting of the Hunterian Society will be held at Pym's, 3, Poultry, London, E.C., on Monday, Oct. 14, at 7.15 p.m. After dinner Dr. J. B. Cook will give his presidential address on the evolution of municipal medicine.

At a meeting of the Society for the Study of Addiction on Tuesday, Oct. 15, at 4 p.m., at 11, Chandos Street, W., Dr. W. R. Bett will read a paper entitled: "Poppies, Dawamesk, and the Green Goddess: an Exotic Study of Literary Genius."

At a meeting of the Royal Anthropological Institute at 21, Bedford Square, W.C., on Tuesday, Oct. 15, at 5.30 p.m., Sir Cyril Burt, D.Sc., will discuss some anthropological problems arising out of work for the Services.

At a meeting of the Royal Microscopical Society in the Hastings Hall of B.M.A. House, Tavistock Square, W.C., on Wednesday, Oct. 16, at 5 for 5.30 p.m., Mr. E. Wilfred Taylor will give a communication on improved image illumination and contrast with the metallurgical microscope. The Biological Section will meet in the Hastings Hall on Nov. 6.

Sir Allen Daley, Medical Officer of Health and School Medical Officer, London County Council, will be installed as President of the Society of Medical Officers of Health for the session 1946-7 and will give his presidential address at a meeting to be held at Tavistock House, Tavistock Square, W.C., on Thursday, Oct. 17, at 5.30 p.m.

The annual meeting of the British Orthopaedic Association will be held in London on Friday and Saturday, Oct. 18 and 19, under the presidency of Mr. George Perkins. On the first day at 1, Wimpole Street, a discussion on fractures of the os calcis will begin at 9.30 followed by the presidential address on "Rest versus Activity in the treatment of a fracture." In the afternoon there will be papers followed by short discussions, and in the evening a dinner at Grosvenor House Hotel. On Saturday, at 9.30 a.m., annual general meeting will be held at St. Thomas's Hospital, followed by a demonstration of cases.

A dinner-meeting of the West London Medico-Chirurgical Society will be held at the South Kensington Hotel, Queen's Gate Terrace, on Friday, Oct. 18, at 7.30 p.m. At 8.15 p.m., the president, Dr. G. S. Hovenden, will give his presidential address on "Fifty Years of General Practice."

The annual general meeting of the Research Defence Society will be held at 26, Portland Place, London, W., on Wednesday, Oct. 23, at 3.15 p.m., when Prof. N. Hamilton Fairley, M.D., F.R.S., will give the fifteenth Stephen Paget Memorial Lecture entitled "War-time research in malaria and other tropical diseases of military significance."

The London Jewish Hospital Medical Society will hold a buffet dance at the Royal Hotel, Woburn Place, W.C., on Saturday, Oct. 26, from 7 to 11 p.m. Any member of the profession interested in this Society can obtain particulars from Mr. J. A. Brodie, 86, Lyncroft Gardens, N.W.6.

On Monday, Oct. 28, at 3 p.m., the Lloyd Roberts Lecture will be delivered at the house of the Royal Society of Medicine by Field-Marshal Viscount Montgomery of Alamein, the title being "Morale with particular reference to the British Soldier." As accommodation is limited only Fellows, Members, and Associates of the R.S.M. may attend and admission will be by ticket.

An exhibition of Swiss planning and building will be open at the Royal Institute of British Architects, 66, Portland Place, W., until Oct. 26. In the section devoted to the health of the community, mountain and ski huts, open-air baths, sports grounds, holiday houses, and restaurants are included, as well as the most modern experiments in hospital buildings. Lack of building materials during the war affected Switzerland badly. Steel, coal, cement, and bricks were scarce. The municipal hospital at Basle, however, the largest hospital in the country, was built entirely during the war years (see *Journal*, Oct. 5, p. 500). This is a fine modern teaching hospital; similar buildings are planned for Zurich and Geneva.

Under the auspices of the Central Council for Health Education a Conference on "Education for Family Life" took place on Sept. 30, at B.M.A. House. The main purpose of the conference was to encourage the free interchange of ideas and experience in open discussion; 54 delegates were present; 57 organizations having been invited to send representatives. Under the chairmanship of Sir Allen Daley (Vice-president), the morning session was devoted to a discussion on "Family Life To-day" and the afternoon session was concerned with the subject, "Educational Possibilities," the chair being occupied by Dr. Charles Hill (Vice-president of the Central Council for Health Education). A very varied, interesting and valuable day was summed up by Prof. H. R. Hamley.

Sir Percival Hartley, F.R.S., Director of Biological Standards at the National Institute of Medical Research, opening the 105th session of the College of the Pharmaceutical Society on Oct. 2, spoke of the remarkable success of the Ministry of Health's campaign against diphtheria. Incidence and death rates had fallen and almost every month some new record was achieved. What would appear to be the last final assault in the present stage of the campaign had now been launched; but, once having attained the goal of immunizing the greatest possible number of children, the percentage must be maintained at the highest possible level. With regard to international co-operation in the field of health he said that those who had used the League of Nations for such purposes had found that the principles were sound and that it could be made to work. The League's Health Organization had been of the greatest value to governments, ports, and ships at sea in matters concerning quarantine. Its work for the international control of certain infectious diseases like typhus, malaria, rabies, and plague represented other important phases of its activities; its concern for the world stocks of quinine and other antimalarial drugs, and for the control of dangerous drugs and drugs of addiction, yet another. Through its activities a valuable and practical step forward had been taken towards the establishment of an international pharmacopoeia, a project which had been under discussion for over half a century. Following a new endeavour, which only got under way in 1937, matters had so progressed that this year a report had been published which could fairly be claimed to be the beginnings and the nucleus of an international pharmacopoeia; rules for its production had been drawn up, a most valuable statement concerning doses compiled, and some fifty monographs presented for adoption.

The Association of Anaesthetists of Great Britain and Ireland will celebrate the centenary of anaesthesia by a dinner in the Great Hall of Lincoln's Inn on Thursday, Oct. 31.

On Oct. 3 the general headquarters of the British Legion were moved from Cardean House, Richmond, to Pall Mall, London, S.W.1: telephone Whitehall 5731. The appeals department and the women's section remain at Richmond.

The *Scotsman* announces that Sir John Boyd Orr, M.D., F.R.S., has informed his election agent in Glasgow that he intends to resign his seat as M.P. for the Scottish Universities. Sir John accepted the office of Director-General of the International Food and Agricultural Organization on the understanding that it would be of a temporary nature and therefore decided to retain his seat in Parliament. Since it is now clear that it will be at least a year before the World Food Board is definitely established he has decided with the utmost reluctance to resign.

The Tuberculosis Educational Institute announces a Refresher Course, at the Literary and Philosophical Library, Westgate Road, Newcastle-upon-Tyne, for medical practitioners and tuberculosis officers, on the treatment of tuberculosis, Nov. 4 to 9; fee, four guineas. Programmes can be had from Dr. Harley Williams, Tavistock House North, Tavistock Square, London, W.C.1.

The College of Midwives is founding a research scholarship to enable a midwife to assist a doctor in hospital research into the use of analgesia in childbirth.

The Services

DEATHS IN THE SERVICES

Lieut.-Col. JAMES MORWOOD, I.M.S. (ret.), has died at the age of 84. Born in Castledawson, Co. Derry, Ireland, he qualified M.D., M.Ch., M.A.O. with honours at the Royal University of Ireland in 1884. He joined the Indian Medical Service in 1886, and after preliminary studies at the Royal Victoria Hospital, Netley, proceeded to India. He took part in the Hazara Expedition of 1888, for which he obtained the India medal with Hazara clasp, and he also took part in the Tirab Expedition of 1897-8, for which he received the India medal with Punjab Frontier and Tirah clasps. After this service on the North-West Frontier he held many civil appointments, finally becoming civil surgeon, Benares, during the period 1914-16, and officer in medical charge of Indian Troops Hospital, Karachi, 1916-18. On his retirement after 32 years of service in India, he returned to settle in Belfast. His main interests throughout his years in Belfast were various philanthropic institutions of a medical nature. He was honorary secretary for many years of the Belfast Branch of the National Society for the Prevention of Cruelty to Children, he was a member of the board of management of Forster Green Hospital for Consumption, and of the board of governors of the Ulster Society for Promoting the Education of the Deaf, Dumb, and Blind. He had been a member of the B.M.A. for 56 years. Col. Morwood married Miss Mary Bell, of California, the daughter of a doctor who served on the Southern side during the American Civil War; she died in 1939. He is survived by two daughters and by three sons, two of whom are in the medical profession.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales there were 134 fewer notifications of whooping-cough and an increase of 62 in the returns for scarlet fever.

Half the decline in cases of whooping-cough was contributed by Yorkshire West Riding 38 and London 32. The largest increase in the incidence of scarlet fever was Yorkshire West Riding 38. Only small fluctuations occurred in the local trends of measles except in Lancashire, where an increase of 60 was recorded.

The largest returns for dysentery were London 14, Lancashire 11, Warwickshire 10. Of the 13 notifications of typhoid 6 were from the Port Health District of Liverpool; these cases were imported from West Africa.

The 240 notifications of diphtheria were 3 below the record low level of seven weeks ago. The only change of note in the local trends during the week was an increase of 11 in Suffolk. In this county 8 of the 12 cases were reported from Halesworth U.D. The largest returns during the week were Lancashire 59, Durham 25, and Yorkshire West Riding 21. In some counties the recent incidence of diphtheria has been very low, and there are twelve counties which during the past two months have had an average of less than one notification each week.

In Scotland the chief feature of the returns was a fall of 20 in the notifications of dysentery. Other decreases were acute primary pneumonia 19, measles 14, whooping-cough 14.

A serious outbreak of ringworm has been reported from Bathgate, West Lothian. Altogether 200 children have been infected in nine schools with a population of 4,000.

In Eire a decline in incidence was recorded for diphtheria 11 and scarlet fever 18, while measles increased by 10 cases. In Dublin C.B. 50 cases of diarrhoea and enteritis were notified.

In Northern Ireland the notifications of scarlet fever increased by 15.

Quarterly Returns for Eire

During the June quarter a birth rate of 24.1 per 1,000 was recorded; this was 0.1 higher than the rate for the two preceding second quarters. The infant mortality was 57 per 1,000 registered births, 2 below the rate for the preceding June quarter. The general death rate was 14.1 per 1,000, an improvement of 0.3 on the June quarter of 1945. Of the deaths under 2 years 184 were attributed to diarrhoea and enteritis. The 746 deaths from pulmonary tuberculosis and 254 from other forms of tuberculosis were 143 and 21, respectively, below the averages of the five preceding second quarters.

Week Ending September 28

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,001, whooping-cough 1,451, diphtheria 285, measles 1,461, acute pneumonia 373, cerebrospinal fever 32, dysentery 66, acute poliomyelitis 30, paratyphoid 19, typhoid 12.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Sept. 21.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Attilology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Accommodation Asthenopia

Q.—*What are the causes of accommodation asthenopia in a young man? Could it be due to syphilis?*

A.—The usual causes are want of proper correction of focus, debility, reading or writing too close to the paper, convergence deficiency, and poor illumination. Less frequent causes are glare—directly from the source of light or indirectly from a glazed paper—and glaucoma. Among the bodily disorders associated with this condition are cited tuberculosis, intestinal disorders, hypopituitarism, neurasthenia, vascular hypertension, and nasopharyngeal, tonsillar, and dental disease.

Unless syphilis is causing active ocular disease it is not a recognized cause of altered accommodation. Treatment is by accurate refraction under a mydriatic and elimination of the above causes.

Vitamin E in Heart Disease

Q.—*Has vitamin E treatment been tried in this country, as in Canada, and particularly in cases of auricular fibrillation?*

A.—With many of the vitamins our knowledge of the clinical effects of deficiency preceded the identification and isolation of the particular factor in the laboratory. Scurvy, rickets, beriberi, and xerophthalmia were well known before the existence of vitamins was realized. Vitamin E on the other hand was discovered as the result of laboratory experiments on reproduction in rats. Extensive investigations have since shown that it is essential for the nutrition of many other animals, including the rabbit, guinea-pig, and chicken, and that it is required for many functions other than reproduction, but evidence that vitamin E deficiency is of clinical importance in the human subject is inconclusive.

Apart from the Canadian claims on which this question is based reasons for testing vitamin E in the treatment of certain forms of heart disease might have been inferred from the results of animal experiments, since muscular lesions, sometimes accompanied by degeneration of the nerves, are a prominent feature in vitamin E deficiency. While these lesions were first described in skeletal muscles and uterus, it has recently been shown the heart is also affected. We have the further point that in the rat the muscular degeneration of vitamin E deficiency is characterized by the deposition of brown pigment granules, which appear on histological examination to be identical with those found in brown atrophy of the senile human heart. There is as yet, however, no evidence on the treatment of myocardial disease with vitamin E in this country.

The results of treatment of the various forms of atrophy or degeneration of the skeletal muscles have generally been disappointing, although American workers have claimed that failure may be due to the faulty absorption of the vitamin. The use of vitamin E in the clinical treatment of auricular fibrillation, even if it is believed to be of myocardial origin, must therefore be regarded as no more than experimental until a critical appraisal of the Canadian claims has been made. A suitable dose for such a trial would appear to be 90 mg. of tocopherol acetate daily, which has been found to be sufficient to cause a definite increase in the level in the blood plasma. Doses of up to 5 g. daily have been given without ill effects.

Intestinal Carbohydrate Dyspepsia

Q.—*What is the treatment for intestinal dyspepsia? Has sulphaguanidine been tried in these cases?*

A.—Intestinal dyspepsia, or intestinal carbohydrate dyspepsia as described by Hurst, is thought to be due to hurry through the small intestine or to a deficiency of its secretions. As a result starch still in its cellulose jacket reaches the large bowel, where it is acted upon by the diastase of the caecal secretions. The starch is freed and is fermented by the bacteria present, which, finding a medium to their liking, multiply rapidly. The particular bacterial flora found in these cases is, therefore, a secondary and not a causal finding. Provided that starch in its cellulose envelope is prevented from reaching the colon the excess of enterococci will die off and treatment with sulphaguanidine will not be necessary. Sulphonamides can have only a limited use in this disorder—the underlying disturbance of function may persist for a long time, and it is impossible to continue chemotherapy for more than a short while.

Diet should not be difficult, even in these times. Sugar and starch which has been liberated from its envelope (e.g., in bread and flour) are well digested in all but the most severe cases and need not be restricted. The following starch-containing vegetables should be prohibited: potatoes, dried peas and lentils, carrots, artichokes, parsnips, beetroot, onions, and rice.

A few drugs may be of value. Codeine 1/4 gr. (16 mg.) may slow up intestinal movements. Charcoal 1/2 oz. (15 g.) in water each morning may help to absorb the gases formed. Constipation is best treated by mucilaginous aperients which will add bulk and fluid to the faeces. Finally, all these patients should be encouraged to return to a normal diet as soon as they have been symptom free for any length of time. This disorder tends to occur in those who are introspective and who take a morbid interest in their bodily functions. A severe neurosis will replace the original complaint unless the sufferers are handled very firmly.

Potassium Thiocyanate in Essential Hypertension

Q.—*How should thiocyanate be administered in treating essential hypertension?*

A.—Potassium thiocyanate is one of the few drugs which appear to lower the blood pressure. Although thiocyanates do not split off hydrocyanic acid they may produce unpleasant toxic effects if the thiocyanate level in the blood exceeds 12 mg. per 100 ml. The dosage necessary to produce this concentration varies considerably, but the risk of toxic effects is remote if the following course is given: potassium thiocyanate 1 1/2 gr. (0.1 g.) in peppermint water thrice daily after food for a week, twice daily for the next week, and once daily for the next two weeks. If control by blood thiocyanate estimations is possible 3 gr. (0.2 g.) may be given daily and increased by 3 gr. (0.2 g.) each week until either a satisfactory fall in pressure is recorded or the blood level reaches the critical value.

Regular blood pressure measurements under uniform conditions should be made every two or three days. A significant fall of blood pressure is produced in perhaps one-third of the patients treated. Relief from headache is experienced in more than half the cases. If the four-week course produces good results either objectively or subjectively it may be repeated when symptoms recur or when the blood pressure rises again.

Toxic symptoms are as follows: weakness, fatigue, drowsiness, and gastric or intestinal disorders. Dermatitis has been recorded even after moderate dosage.

Action of Ung. Ichthyol

Q.—*What is the action of ung. ichthyol upon inflammation?*

A.—Ichthammol, obtained by treating fossilized fish deposits with sulphuric acid and neutralizing the distillate with ammonia, contains about 10% of sulphur in the form of organic sulphonates. It has to some extent the properties of sulphur—mildly antiseptic and parasitocidal—but is non-irritant and has the reputation of being demulcent. Its use is empirical and is probably related to its black colour and unpleasant smell. Its value is doubtful and many dermatologists find little use for it.

Pneumothorax and Air Travel

Q.—Is it dangerous for a man with a small pneumothorax to fly to the United States? I know there is a theoretical objection to flying at high altitudes, but is there even a moderate risk either of syncope or of lighting up a tuberculous focus?

A.—I think it is most inadvisable for a man with a small pneumothorax to fly to the United States with perhaps twelve hours at 10,000 ft. (3,000 m.) and the possibility that the pilot may go rather higher if the weather necessitates it. Cases tested in the decompression chamber have shown considerable distress with short exposure to 9,000 ft. (2,700 m.). If the man in question can be tested in a decompression chamber he may find that he has no disturbance or pain, in which case there would be little risk in travelling by air, but I think it would be dangerous to travel without such a test.

Intervertebral Disk Lesions

Q.—1. What is the characteristic syndrome by which sciatica due to a lesion of an intervertebral disk can be diagnosed clinically? 2. Can a diagnosis be made with sufficient confidence to justify laminectomy? 3. What is the significance in a case of sciatica of narrowing of the disk between the fifth lumbar and first sacral vertebrae and of a comparatively straight lumbar spine as shown on straight x-ray? 4. Does a negative finding on myelography contraindicate laminectomy? 5. How is the operation performed, and are the results good?

A.—1. *Characteristic Syndrome.*—It is important to realize that disk protrusions occur under variable circumstances. There are two characteristic stories. A person lifting a heavy weight feels something "give" in the back. There is intense lumbago or sciatica, and the individual is unable to straighten up. Or there may be no recent injury. Sometimes there has been an accident some months earlier producing no obvious back pain—e.g., a fall on to the buttocks. Many months later sciatica develops, perhaps precipitated by some minor effort, say a cough or a sneeze. It is probable also that an intervertebral disk can be damaged by the repeated but usually unnoticed strains of an active athletic life.

The typical clinical picture includes: (a) Sudden onset of acute "lumbago" or "sciatica," usually in a young person, markedly aggravated by coughing, sneezing, or straining at stool. (b) Scoliosis which may be towards or away from the leg in which the pain is felt; or reversal of the normal lumbar curve; or deviation of the trunk to one or other side on bending forward. (c) Spasm of the posterior spinal muscles so that flexion and extension are limited and painful but lateral flexion and rotation are relatively normal. (d) Tenderness above or at the level of the posterior superior iliac spine on the side of the sciatica. Sometimes deep pressure at these levels will cause pain referred along the sciatic distribution. There is often marked tenderness along the course of the sciatic nerve. (e) Painful limitation of "straight leg raising"—i.e., active and passive limitation of flexion at the hip with the knee fully extended and the patient recumbent. This restriction is most marked on the affected side but is often present on the opposite side as well. There are several methods of eliciting this test. (f) Loss of tone, wasting, and weakness of the buttock, and the posterior or anterior calf muscles. (g) Anaesthesia or hypoaesthesia of the outer aspect of the calf and the outer or inner borders of the foot. (h) Diminution or absence of the ankle jerk, usually on the affected side but occasionally on the opposite side if the prolapsed disk is centrally placed.

There are wide variations of this clinical picture. For example there may be no sciatic pain at all—indeed it is becoming increasingly clear that recurrent attacks of acute lumbago are due to prolapsed intervertebral disks. The spine becomes temporarily "locked" in the same way as the knee when a torn meniscus is displaced. Again the neurological pattern is variable, so that in some there are sensory changes and no motor or reflex abnormalities, and vice versa. The common sites of disk protrusion are the interspace between the fourth and fifth lumbar vertebrae producing pressure on the fifth lumbar root, and the interspace between the fifth lumbar and first sacral with pressure on the first sacral root. Broadly speaking the fifth root syndrome is weakness of the

anterior tibial group of muscles with hypoaesthesia of the outer aspect of the calf and the inner border of the foot, the ankle jerk being normal. Pressure on the first sacral root causes weakness of the gluteus maximus and posterior calf muscles, hypoaesthesia of the outer aspect of the calf and outer border of the foot, and changes in the ankle jerk.

2. *Diagnosis* can be made by clinical and x-ray examination with confidence. The condition which most closely mimics the disk syndrome is spondylolisthesis. It is obviously important to carry out an examination sufficiently thorough to exclude such lesions as neoplasms in the spinal column, or tuberculous or other inflammatory processes in the lumbar spine or pelvis. In actual fact these conditions rarely cause confusion.

3. *Narrowing* of an intervertebral space as shown in a straight x-ray may mean degeneration of the disk material, but it certainly does not always indicate the disk which is causing the sciatica. Opinion is divided about its significance.

4. *Myelography* is nowadays rarely employed for the diagnosis of a straightforward prolapsed disk. Occasionally when there is doubt about the cause of sciatica or about the location of the root pressure it is valuable. Lipiodol has been discarded in favour of non-irritating contrast media, such as "pantopaque," which can be withdrawn more easily. A negative myelogram is by no means a contraindication to operation.

5. *Treatment.* Most surgeons advise operation if the sciatica or lumbago does not subside after three to six weeks' rest in bed, or after immobilization in a plaster jacket or spica, or if recurrences are frequent. Operation is justified in these circumstances on clinical and straight x-ray examination alone. The operation is performed extrathecally. Most neurological surgeons excise the prolapsed material through an interlaminar approach, removing the ligamentum flavum and a mere nibble of bone; orthopaedic surgeons favour the performance of a modified laminectomy, taking care to avoid damage to the facet articulations. The important thing is for the procedure to be carried out by an expert. In his hands the operation carries no special risk and the results are excellent. In long-standing recurrent cases the quality of recovery is not so good as in recent cases—and the convalescence tends to be longer. This is no doubt due to changes in the nerve root from long-continued and oft-repeated irritation.

Nervous Breakdown

Q.—What is a nervous breakdown?

A.—Biologically speaking, a "nervous breakdown" is the inability of the personality to cope with the problems and difficulties of life. In its adaptation to life the mechanism of response breaks down. It refers to a failure in response of the personality as a whole and not usually to a breakdown due to specific diseases like disseminated sclerosis. It depends on two factors, the severity of the objective stress and the constitutional inability of the individual to stand the strain. In some cases, as in war shock, the objective traumatic factor may be the more important. But according to modern psychological opinion a "nervous breakdown" is rarely caused by objective conditions alone. Even in traumatic conditions like "shell shock" we find there are predisposing causes, which is why one man breaks down under such conditions and another does not. The instability of the individual is the most important factor. This instability may be innate and constitutional or acquired. If the instability is of a constitutional kind the breakdown is usually of the nature of a "psychosis," and is not spoken of as a "nervous breakdown." In the majority of cases the term is used of those conditions in which the instability is the result of subjective causes, such as emotional conflicts and internal stresses, which so weaken the organism that it is rendered incapable of withstanding even the ordinary stresses of life, and so breaks down. That is why a patient so often breaks down for no apparent cause. (Of course even in these cases physical fatigue, toxic conditions, and constitutional sensitivity may be contributory causes, but it is the mental fatigue due to the strain of subjective conflict which is the important factor undermining the personality.) These conflicts may be between strong emotions like fear and aggressiveness or sex; but the most deep-rooted conflict is that between the native impulses of the natural self and the demands made upon him by society, and the demands which he makes upon himself.

the Minister, whose opinion could be challenged in the House of Commons.

The motion, that the Bill cannot produce the best health service for the nation, was put to a show of hands, and declared by the Chairman to be carried by 149 votes to 139.

SALARIES OF WHOLE-TIME MEDICAL OFFICERS AT MENTAL INSTITUTIONS

The interim revision of the Askwith agreement published with Ministry of Health Circular 140 did not cover all appointments held by medical officers in mental hospitals because certain of these appointments have never come within the scope of the Askwith agreement. Negotiations were immediately begun between the British Medical Association and the Mental Hospitals Association and a conference was held at which representatives from both Associations agreed the principles for an interim revision of remuneration for medical superintendents, together with other grades of medical officers, employed at mental hospitals and mental deficiency institutions. Representatives of the L.C.C., who were also present, agreed to consider the application of the recommendations.

The document, drawn up as a result of the discussions, has been approved by the Councils of both Associations and has been issued by the M.H.A. to all authorities responsible for the administration of the mental hospitals and mental deficiency institutions with a request that the recommendations be implemented retrospectively from April 1, 1946. Details of the interim revision are set out below.

AGREED DOCUMENT

Interim revision of remuneration of medical superintendents, and other grades of medical officers employed at mental hospitals and mental deficiency institutions not covered by the interim revision of the Askwith Memorandum, agreed to at a Conference between representatives of the Mental Hospitals Association and British Medical Association.

(1) The salaries of medical officers in mental hospitals and institutions for the mentally defective (other than assistant medical officers already dealt with in the interim revision of the Askwith Memorandum) shall be increased as follows:

(a) if the datum salary does not exceed £700, by 30% of that salary;

(b) if the datum salary exceeds £700, but does not exceed £1,000, by 20% of that salary;

(c) if the datum salary exceeds £1,000, by 10% of that salary;

provided that no officer shall have an automatic entitlement to a total salary greater than that produced by the addition to the maximum of the scale of pay as at Sept. 3, 1939, attached to the position he occupies, of the appropriate percentage increase of the datum salary for the position.

(2) For the purposes of the foregoing paragraph "datum salary" shall—

(a) subject to adjustment as provided in (c) below, be for officers in service on Sept. 3, 1939 (and continuously employed thereafter to the date of issue of this Memorandum), the minimum of the scale of salary attached to the material position at Sept. 3, 1939;

(b) subject to adjustment as provided in (c) below, be for officers appointed after Sept. 3, 1939, the minimum of the scale of salary attached to the material position either at Sept. 3, 1939, or at the date of appointment whichever is the lower;

Note to (a) and (b):

(i) Wartime service shall not be regarded as breaking the continuity of appointment.

(ii) Where there is no scale and the officer has been in office for some years regard should be had to increments, which he has received during the few years preceding 1939, for the purpose of determining a notional scale. If there have been no increments the salary in operation is the commencing salary for the purposes of this agreement.

(c) be assessed on a resident basis and shall be the net cash amount remaining after (A) deduction of the individually

agreed charges for board, lodging, and washing where gross salaries, subject to deductions for residential amenities provided, are payable; and/or (B) exclusion of the value of emoluments provided in kind or services;

(d) not include any payment made in respect of possession of the D.P.M.

(3) Individual cases where there is doubt should be referred for joint consideration by the Mental Hospitals Association (or the employing authority concerned if not a member of the Mental Hospitals Association) and the British Medical Association.

(4) The foregoing arrangements, which are without prejudice to any subsequent negotiations upon scales of remuneration in the National Health Service and are in addition to war bonus are to have effect as from April 1, 1946.

(5) Marginal adjustments shall be made to ensure that a officer to whom a 20% increase applies shall receive a revised salary of not less than £910 per annum, and that an officer to whom a 10% increase applies shall receive a revised salary of not less than £1,200 per annum, and in the case of incremental scales the amount of the increase, as adjusted, be applied throughout the scale.

(6) In cases where present salaries are such as to disqualify their recipients, either in whole or in part, from receipt of the salary increases now agreed, employing authorities clearly have discretion to review existing rates of remuneration.

MEDICAL STUDENTS AND THE HEALTH SERVICE BILL

The British Medical Students' Association has tried to assess the reaction of medical students to the National Health Service Bill by means of a questionnaire which was distributed to the students in every medical school in England, Wales, and Scotland with two exceptions—a total of 10,106. Of these 3,801 replies were received—i.e., 37.6%. Results were obtained separately from England and Wales, and from Scotland, but they are substantially the same, and unless separate mention is made of Scotland, remarks apply to the over-all figures.

Summary of the More Important Findings

Only a small proportion (17%) of students are definitely opposed to the principle of a comprehensive National Health Service—slightly over 80% being in favour. The detailed provisions of the Bill are not so widely approved. Slightly over 40% (43% England and Wales, 41% Scotland) feel that the Bill will improve the medical services of the country, and 40% (41% England and Wales, 40% Scotland) think it will cause a deterioration. Thus opinion on the Bill as a whole is almost evenly divided.

The principle of a general practitioner service is approved by a 3:1 majority, but the transference of the hospitals to the Ministry of Health is not approved, a small majority preferring the hospitals to remain under present administration.

Most of the remaining questions deal with details, based on the assumption that there is to be some form of health service on the lines proposed. Medical student opinion is strongly in favour of the doctor (whether specialist or general practitioner, newly qualified or well established) being allowed simultaneously to conduct private practice along with his work in the Service—as is proposed by the Bill. However, an appreciable minority (26% with reference to newly qualified practitioners, 20% with reference to specialists and established practitioners) oppose this plan. Health Centres are approved (about 50% in favour and about 30% against). The combination of salary and capitation fees is approved (64%)—but 18% favour capitation fees alone and about 12% salary alone. The prohibition on the sale of N.H.S. practices (as proposed by the Bill) is accepted (53% for, 40% against); but, again by a small majority, the power of the Medical Practices Committee to prohibit a doctor from practising in a particular area is not approved (47% for, 50% against). Nearly 60% disagree with the composition of the Executive Councils—almost all those saying why they disagree doing so because they wish to see more professional men on the councils. Free refresher courses for doctors are non-controversial, 98% of students favouring the idea. So far as the hospitals are concerned, students disapprove of the transference of the endowments of voluntary hospitals to a new fund for redistribution, and agree that the teaching hospitals should be administered separately, as is conceded by the Bill.

In spite of disagreement with certain details and an uncertain approval of the Bill as a whole, over 60% of the students who answered the questionnaire expressed a willingness to work in the

the National Health Service if it comes into force or anticipated inevitability of having to work in it. All this is provided that the provisions of the Spens Report (which had not at that time been published) are acceptable, and that such Regulations as the Minister may make under the Bill are also acceptable.

HEARD AT HEADQUARTERS

International Achievement

An assembly of representatives of thirty nations in Tavistock Square, with the British Medical Association as host, was a noteworthy event, and incidentally furnished a good example of international conferences in general. Within 48 hours this conference had achieved what it set out to achieve: it had set up a World Medical Association, had given it a local habitation—or two habitations, one in London and the other in Paris—and a name; it had also decided the subscription and appointed a provisional committee and the secretariat. One of the happy things about the conference was the interpretation service. There were two interpreters, one to translate from the French into English and the other from the English into French. One of them was Dr. Gilder, who has a number of languages at his command; the other was Miss Lagarde, who works for the British Council. Both of them were highly complimented on the skill they showed in removing the language barrier. Many of the delegates, both the English-speaking and the French-speaking, were bilingual, and the Conference would doubtless have come to some conclusion without any interpretation at all, but when it came to the exact phraseology of resolutions and the details which will presently be embodied in by-laws their assistance was of the greatest value.

The Closed Shop

One of the many matters which the Public Health Committee of the B.M.A. will have before it at its next meeting is the issue of the "closed shop," which has now thrust its sulky head into medical affairs. It is stated that certain local authorities have passed resolutions requiring all their employees to become members of their appropriate trade unions. In certain instances it has been intimated that these resolutions are not to be interpreted literally, and that so far as medical officers are concerned membership of the B.M.A. will satisfy the condition. One authority says that that will not be sufficient, but that membership of N.A.L.G.O. will be required; and yet another requires membership of the Medical Practitioners' Union as a condition of appointment. With the repeal of the Trades Disputes Act local authorities have now the legal right to require membership of a trade union as a condition of appointment to their staffs.

The B.M.A. is not a trade union: it is a limited company with the licence of the Board of Trade to omit the word "limited" from its title; but it is the body recognized by the Government and by the various associations of local authorities as the negotiating body on behalf of the profession; moreover it is recognized by the T.U.C., with which it is in liaison. This matter of trade unionism has often been before the B.M.A. Opinion of counsel was sought many years ago, and has been obtained again,¹ and is to the effect that if the Association desired to become a trade union it would have to be completely reconstructed. A new association would have to be formed to which the B.M.A.'s present assets could not be transferred; and, moreover, the objects would have to be drastically revised; for whereas the present objects are to promote the medical and allied sciences and to maintain the honour and interests of the profession, the first object of a trade union is the regulation of relations between workmen and masters. The legal view is that medical men are neither the one nor the other within the meaning of the Trade Union Acts.

As Others See Us

It has been very interesting to discover at the two international medical gatherings of the last fortnight, the one at Basel attended by British and Swiss doctors, and the other in

London attended by doctors from a score of European countries, how well informed the men from other countries were concerning the controversy between the British medical profession and the Government. It was evident that the Swiss had a keen appreciation of the issues involved. One Dutch doctor knew all about the Spens Report and the insurance capitation fee. Many expressions of sympathy with the stand which the Association has made were forthcoming from French and Belgian colleagues, and were all the more valuable for being based on a sound knowledge of the issue. Criticism, however, came from a Belgian delegate. "We Belgians," he said, "know how to speak our minds. We say 'No,' and when we say 'No' we mean 'No,' and when we mean 'No' our Government knows that we mean 'No.' You English, on the other hand, are too fond of mincing your words. You use too many polite phrases. You are too much inclined to compromise." Certain statements made by the Association which seemed to lack nothing in point and directness were quoted to him, but he was not convinced. "We are an obstinate people. We Belgians. The Germans said so."

Correspondence

A Word to Hospital Staffs

SIR,—In a recent circular to hospitals the Minister has stated that he is prepared to consider financial help during the interim period before the commencement of the National Health Service, such financial assistance to include a sum for the honorary medical staff. We understand that some hospital staffs may be inclined to accept such payments on the grounds that if eventually they are to be paid by the State why not begin now. If this be the attitude of any considerable number of consultants they are merely playing into the hands of the Minister, since he would say the consultants only need to be bribed in order to make them work his Bill. What then is the use of hospital staffs passing resolutions deploring the handing over of hospitals to the State if in the next breath they begin to ask for money?

Since a plebiscite is to be taken on the question whether the medical profession will negotiate with the Minister about the regulations he intends to issue, any action of hospital staffs on the above line will only weaken the unity of our profession, and is therefore to be deplored. Let all medical committees, when this subject is discussed by them, see the importance of this principle and fight against any interim payment to them from the Government. If they do not they are accepting this Bill and are adopting a defeatist attitude.—We are, etc.,

T. MEYRICK THOMAS.
W. SMITH.

GEOFFREY PARKER.
COLIN EDWARDS.

Resistance to New Capitation Rate

SIR,—In organizing any resistance to the new capitation rate for N.H.I. patients which may be decided on, full consideration must be given to the weakness of human nature. There are two main dangers in the idea of mass resignations: (1) Black-legs—those who promise but do not fulfil. (2) The pool of unemployed doctors. The first danger would largely be prevented by insisting that all resignations be completed and sent under cover to the local Divisional Secretary of the B.M.A. He, poor man, will thus know (a) those who are not resigning; and (b) those who, having resigned via him, cancel it directly and break their promise. The second danger must be assessed by those more familiar with the necessary statistics than I.—I am, etc.,

Cromer.

A. HENRY GREGSON.

RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Dr. W. Lindesay Neustatter, at 125, Harley Street, W.1 (Welbeck 3656); Mr. D. J. MacRae, F.R.C.S. at 10, Harley Street, W.1.

¹ See Supplement, Sept. 21, 1946, p. 83.

Association Notices

Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of fifty guineas, is again open for competition. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of fifty guineas.
2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.
3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.
4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1946. The prize will be awarded at the Annual General Meeting of the Association to be held in 1947.
5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.
6. If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.
7. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto, and enclosing the candidate's name and address.
8. The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal*, or for presentation to the appropriate Section of the Annual Meeting of the Association.
9. Inquiries relative to the prize should be addressed to the Secretary.

Diary of Central Meetings

OCTOBER

17. Thurs. Publishing Subcommittee, 11 a.m.
Journal Committee, 2 p.m.
23. Wed. Special Meeting of Council, 12 noon. (Change of time.)

Branch and Division Meetings to be Held

- AYRSHIRE DIVISION.—At Seafield Hospital, Ayr, Sunday, Oct. 20, 7 p.m. Clinical meeting.
- DORSET DIVISION.—At Dorset County Hospital, Dorchester, Thursday, Oct. 24, 3 p.m. B.M.A. Lecture by Mr. D. G. Wilson-Clyne: Breech Presentation. All doctors residing in the district are invited to attend.
- SOUTH BEDFORDSHIRE DIVISION.—At Luton and Dunstable Hospital, Wednesday, Oct. 23, 9 p.m. Dr. H. Guy Dain: The National Health Service.

APPOINTMENTS

- BRADFORD JOINT HOSPITALS COUNCIL.—Visiting Staff. At St. Luke's Hospital and Bradford Royal Infirmary: Physician, J. A. Price, M.D., M.R.C.P. Assistant Physicians, C. L. Davidson, M.D., M.R.C.P., L. W. Smith, M.B., M.R.C.P. Surgeons, J. Dawson, F.R.C.S., G. Whyte Watson, F.R.C.S. Ed. Assistant Surgeons, J. S. Davidson, F.R.C.S. Ed., F. R. Martin, F.R.C.S. Obstetrician and Gynaecologist, G. W. Theobald, M.D., F.R.C.S. Ed., F.R.C.O.G. Orthopaedists, I. A. G. L. Dick, M.D., Ch.M., F.R.C.S. Ed., A. Naylor, Ch.M., F.R.C.S. At St. Luke's Hospital and Bradford Children's Hospital: Paediatrician, R. L. Langley, M.D. At Bradford Royal Eye and Ear Hospital: Ear, Nose, and Throat Surgeon, J. H. Outy, F.R.C.S. Ed. Ophthalmologists, J. Benson, F.R.C.S. Ed., R. I. T. Lloyd, F.R.C.S. Full-time Staff. At Bradford Royal Infirmary: Pathologist, H. S. Kellith, M.B., B.Chir. Radiologists, R. J. C. Campbell, M.B., Ch.B., R. J. Carr, M.D., R. L. Lewis, M.D. Each appointment carries consulting duties at all the four hospitals concerned.
- GILLIES, I. HUNTER, M.D., D.P.M., Deputy Medical Superintendent, Crichton Royal, Dumfries.
- LYOYD, J. P. F., F.R.C.S., Senior Surgeon, Oxford Eye Hospital, Walton Street, Oxford.
- MORFEL, M. P., F.R.C.S., Honorary Surgeon, North Devon Infirmary, Barnstaple.
- NATIONAL HOSPITAL, Queen Square, W.C.—Honorary Assistant Physician, M. J. F. McArdle, M.B., B.S. Assistant Radiologist, J. W. D. Bull, M.B., B.Chir.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Pathology.—Tues., 4.30 p.m. Communications.
General Meeting of Fellows.—Tues., 5.30 p.m. Ballot for election to the Fellowship.

Section of History of Medicine.—Wed., 2.30 p.m. Special meeting to commemorate the centenary of the practical introduction of anaesthesia. Prof. Charles Singer: Anaesthesia in the pre-anaesthetic period (before 1846). Dr. Barbara Duncum: The development of inhalation anaesthesia in the second half of the 19th century. Dr. Joseph Bloomfield: The modern development of anaesthesia (1900–1935). Dr. E. Ashworth Underwood: A contribution to the early history of anaesthesia in this country.

Members of the Sections of Anaesthetics and Surgery are specially invited to attend.

After the meeting those present are invited to the exhibition of anaesthetic apparatus and literature at the Wellcome Historical Medical Museum, 183, Euston Road, N.W., which will be open at approximately 4.15 p.m. by Lord Moran, P.R.C.P.

Section of Comparative Medicine.—Wed., 5 p.m. Presidential address by Prof. G. R. Cameron: Shift of body fluids.

Section of Dermatology.—Thurs., 5 p.m. Cases will be shown.
Section of Radiology.—Fri., 5.30 p.m. Presidential address by Dr. Whately Davidson: A basis for staffing a radiological department.

Section of Obstetrics and Gynaecology.—Fri., 8 p.m. Presidential address by Mr. James Wyatt: The future teaching of the undergraduate.

HUNTERIAN SOCIETY.—At Pimm's, 3, Poultry, E.C., Mon., 7.15 p.m. Dinner meeting. Presidential address by Dr. J. B. Cook: Evolution of Municipal Medicine.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, W.C.—Fri., 5 p.m. Dr. I. Muende, Fungus Infections of the Skin.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.—Mon., 8 p.m. Annual General Meeting. 8.30 p.m., presidential address by Philip Manson-Bahr: Biological Basis of Tropical Medicine.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Fri., 3 p.m. Harveian Oration by Sir Maurice Cassidy: Cora Disease.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At Portland Place, W., Thurs., 8 p.m. Dr. C. J. Hackett: Clinical Course of Yaws in Uganda. Film: Yaws in Uganda.

POSTGRADUATE NEWS

The University of Leeds Postgraduate Subcommittee announces that it is proposed to hold a two-weeks general refresher course. Class II demobilized medical officers and insurance practitioners beginning on Monday, Nov. 25. Applications and inquiries should be addressed to the Senior Administrative Officer, School of Medicine, Leeds.

The Fellowship of Postgraduate Medicine announces the following courses: (1) Obstetrics and gynaecology, for general practitioners daily, Oct. 14 to 19, at Queen Charlotte's and Chelsea Hospital. (2) Week-end course in rheumatism, all day Saturday and Sunday, Oct. 26 and 27, at Rheumatic Unit, St. Stephen's Hospital, Ful Road, S.W. (3) Course of six lectures on Clinical Aspects of Psychiatry, on Tuesdays and Wednesdays, at West End Hospital, Nervous Diseases, Nov. 5 to 20, afternoons.

WEEKLY POSTGRADUATE DIARY

- BLACKPOOL: VICTORIA HOSPITAL.—Thurs., 8 p.m. Dr. Blackledge: Papilloedema.
- EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Edinburgh Royal Infirmary, Tues., 5 p.m. Prof. F. A. E. Crew: The Pathology of Genetics in Clinical Medicine.
- GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—Fri., 8 p.m. Prof. Loewenstein: Phakomatoses.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or Extra words 3s. 6d. for each six or less. Payment should be forwarded to the notice, authenticated by the name and permanent address of the person should reach the Advertisement Manager not later than first post following.

BIRTHS

- BROWNIDGE.—On Sept. 26, 1946, at the Maternity Home, Aberystwyth, Phyllis (née Peck), wife of Dr. C. E. Brownridge, a daughter.
- HARTNELL.—On Sept. 28, 1946, to Eileen (née Field), wife of Major Roy Hartnell, M.B.E., R.A.M.C., a son.
- JONES.—On Sept. 28, 1946, at Leamington, to Gladys (née Leigh), wife of H. M. Jones, a daughter.
- OXENHAM.—On Sept. 30, 1946, at North Middlesex County Hospital, Marjorie, wife of Dr. L. W. Oxenham, 31, First Lane, N.21, a son.

MARRIAGE

- WAGNER-WILSON.—On Sept. 30, 1946, at Bristol, Major Michael Wagner, M.B.E., to Elizabeth Nan Russell Wilson, M.B., Ch.B.

LONDON SATURDAY OCTOBER 19 1946

TEETH OF 5-YEAR-OLD LONDON SCHOOL-CHILDREN

(SECOND STUDY)

A COMPARISON BETWEEN 1929, 1943, AND 1945

BY

MAY MELLANBY

(Nutrition Building, National Institute for Medical Research, N.W.7)

AND

HELEN COUMOULOS, Ph.D.Camb., D.D.S.Athens

(Girton College, Cambridge)

Between May, 1943, and the end of January, 1944, the mouths of a large number of children aged 5 years and attending L.C.C. schools were examined and charted* and a preliminary report on this survey was made (Mellanby and Coumoulos, 1944). One of the objects of the work was to compare the condition of the deciduous teeth of these children with that of children of the same class and age group examined in 1929, when a survey on similar lines, but with a less elaborate system of charting, was made by one of us (M. M.).

In order to make the two investigations as nearly comparable as possible the same schools were chosen in 1943 as in 1929, any which were no longer available being substituted by others of similar type in the same district. The number of children examined in these schools was 1,604. In addition, examinations of 266 children were made in a few schools in districts not visited in 1929, but these were not included in the main survey as they were not truly comparable.

In the report on the 1929 survey published by the Board of Education (1931), figures were given only in relation to children and not to the individual types of teeth. For the sake of comparison, therefore, the 1943 results were given in the same form, and it was clearly shown that, as regards both structure of the teeth and caries, the general dental condition was much better than in 1929. A summary of the findings in the two surveys is given in the following quotation from the report:

"It is clear that in the 14 years that have elapsed the picture of deciduous tooth structure has changed for the better. Even so, there are very few children with a full complement of perfectly calcified teeth; however, in 1943 18.1% had only slight M-hypoplasia compared with 7.8% in 1929, and there were fewer with much M-hypoplasia—33.3% as against 58.5% respectively. . . . 22.4% of the children in 1943 were 'caries-free,' compared with 4.7% in 1929; and only 29.3% had much caries, as against 62.8% previously."

Since very few of the children were free from caries in 1929 it was decided to include in the caries-free group any who had only one or two teeth which, according to the standards used, were probably carious to a very slight degree. Even so, as is seen from the figures quoted, only 4.7% of the 1,293 children examined came into the so-called caries-free group. (It should be noted here that the standards were much more severe than those adopted at that time in routine inspections by school dental surgeons, which are made for purposes of treatment.)

The 1943 estimate of caries-free children as 22.4%, given in the report (Mellanby and Coumoulos, 1944), was assessed on the same basis as the 1929 figure for purposes of comparison, but in arriving at the assessment a distinction was made between those in whom no caries could be diagnosed by the methods employed and those in whom there were one or two teeth showing very slight caries.

It is intended in the present paper to give the structure of, and the amount of caries in, the individual types of teeth as found in 1943 and to compare them with data obtained in an investigation made in 1945, the object of which was to ascertain whether the great improvement found in 1943 as compared with 1929 was maintained. Sample schools from each district visited in 1943 were taken for this purpose and the mouths of 691 5-year-old children were charted. The length of time that elapsed between the first of the 1943 and the last of the 1945 inspections was 26 months, and the average period between the inspections in the schools visited in both investigations was just over 20½ months.

Methods

All children of the age of 5 years (i.e., up to but not including the sixth birthday) at school on the day of the examination came under survey. This is a useful age group for the study of deciduous teeth, since few have been naturally shed and all have been subject to post-eruptive influences for a considerable period—the anterior teeth for 4 to 5½ years and the posterior for 3 to 4 years. The percentages of teeth present in the mouths at the time of inspection are shown in Table I.

TABLE I.—Percentages of Teeth Present at Time of Inspection

Type of Tooth	1943	1945
Upper:		
Centrals	90.7	92.6
Laterals	96.0	93.3
Canines	99.8	93.6
1st molars	90.5	95.0
2nd molars	92.4	97.5
Lower:		
Centrals	83.2	79.4
Laterals	97.9	93.0
Canines	99.9	93.9
1st molars	85.3	92.4
2nd molars	86.0	91.7
All types	92.2	94.4

In an ordinary room, with the best light available, each child was subjected to as detailed an examination of the individual

* For the sake of brevity this is referred to as the 1943 survey.

* See note at foot of Table III.

Caries

The incidence and extent of caries, expressed as percentages and as average caries figures (ACF)* are shown in Table IV. As in the previous table, data are given for each type of tooth and for all types taken together. The unbracketed figures in the column headed "C₁" include missing canines and molars, which were assumed to have been extracted for caries (see p. 566). The figures in brackets show these teeth as percentages of the total number (see column 2).

In Table IV it is seen that there was less caries in 1945 than in 1943. In the earlier period 69.9% of the teeth were caries-free, while in the later the figure had risen to 73.5%—a difference of $3.6 \pm 0.46\%$, which is significant statistically. Taking the more severe degrees of caries (C₂ and C₃) together, the percentage so graded in 1945 was slightly lower than in

(Dental Disease Committee, Medical Research Council, 1936) that in controlled dietetic investigations on children a striking feature in the groups having a good calcifying diet rich in vitamin D was the relatively high proportion of teeth in which the carious process was no longer active but had become or was becoming arrested. Many of the children concerned in the Sheffield investigations were under observation for a period of several years, and it was found possible in some cases to trace the gradual arresting of the carious process until the final hard, smooth, and polished state was reached. When a tooth showing this "healing" or arrest was sectioned after being shed or extracted it was usually found to contain a large amount of well-calcified secondary dentine. On the basis of animal experiments (Mellanby, 1923, 1930) it seemed feasible to conclude that the deposition of this secondary dentine was

Total caries figure

* ACF (average caries figure) = $\frac{\text{Total caries figure}}{\text{Total no. of teeth (including extractions)}}$

† See above.

1943 (20.3% compared with 22.7%), and the same trend is apparent, except in the case of the lower canines, when each type of tooth is taken separately. In both investigations the upper incisors, which were of much worse structure than the lower, were also much more carious, the upper centrals being more affected than the laterals. The average caries figures (ACF) tended to be lower in 1945 than in 1943 for all types of teeth together as well as for each individual type.

Arrest of the Carious Process

A point of much interest and, we believe, of great significance is the arrest—or, as Miller called it, the spontaneous "healing"—of the carious process, which represents a measure of the defensive reaction of a tooth to attack by caries. It was shown in investigations in Sheffield (Mellanby, Pattison, and Proud, 1924; Mellanby and Pattison, 1926, 1928) and Birmingham

related to the arrest of caries and to the type of diet eaten at and after the time of the carious attack.

In the surveys here described arrest was recorded only when the carious area had become definitely hard, though not necessarily smooth and polished. It is interesting to note in Table V that in 1943 11.7% of the carious teeth present in the mouths of the children examined showed arrest and that in 1945 the percentage was almost doubled—i.e., 21.5%. Had teeth showing earlier stages of arrest been included the figures for both surveys would undoubtedly have been much higher.

TABLE V.—Teeth Showing Arrest (Spontaneous "Healing") of the Carious Process

	No. of Carious Teeth Present	% Carious Teeth Present Showing Arrest
1943	9,182	11.7
1945	3,293	21.5

* See note at foot of Table IV.

Treatment of Carious Teeth

In Table VI are shown the percentages of carious teeth assumed to have been extracted (that is to say, the missing canines and molars) and the percentages which had been treated by silver nitrate application or had been filled. It will be seen

TABLE VI.—*Carious Teeth Extracted, Treated by Silver Nitrate, or Filled*

NOTE.—This table does not include the few teeth shown under the heading "Hy Unclassified" in Table III.

that there was less treatment of all kinds in 1945 than in 1943. This may, of course, be because there were fewer dental surgeons to cope with the work.

Relationship between Structure of Teeth and their Susceptibility to Caries

Attention has been drawn by one of us (M. M.) and by others using the same criteria (Davies, 1939; Dental Disease Committee, 1936; King, 1940) to the fact that there is a direct relationship between the structure of the deciduous teeth, according to the standards used, and their susceptibility to caries: the less the M-hypoplasia the less, in general, the caries. In the investigations described in this paper the same relationship is evident, as is seen from Table VII.

When the teeth were of good structure (Hy.) only 1.1% of the incisors, 1.5% of the canines, and 8.3% of the molars were carious in 1943, and the corresponding figures for 1945 were 1.2%, 1.1%, and 7.0%. With each degree of M-hypoplasia the percentage of carious teeth increased in both surveys, until with very hypoplastic structure (M-Hy.) there were in 1943 80.4% of incisors, 61.1% of canines, and 87.1% of molars carious, and in 1945 81.0% of incisors, 68.9% of canines, and 92.3% of molars.

The incidence of caries in teeth with gross hypoplasia was not as great as in those with severe M-hypoplasia. This is understandable because, although the enamel of part of a tooth may

TABLE VIII.—*Amount of Caries in Relation to Superficial Staining of Teeth*

Children with	Percentage of Carious Teeth		ACF	
	1943	1945	1943	1945
(a) No stain	30.1	23.1	0.66	0.48
(b) Black and dark-brown stains	19.3	15.4	0.41	0.30
(c) Green stain	33.4	33.0	0.72	0.69

be badly pitted, or even missing, the remaining enamel, laid down at a different period of growth, may be quite well formed. For this reason it was decided, in tabulating the relationship between structure and caries, not to combine teeth showing gross hypoplasia with those affected by severe M-hypoplasia, as was done in some earlier surveys (Mellanby, 1934).

Staining of Surface Enamel or of Films on the Enamel

Very little appears to be known about the superficial staining seen on the teeth of many children. It is often unsightly

and difficult to remove by ordinary brushing, and, if removed, usually returns. In the surveys here recorded the most common stains observed were black, very dark brown, or green. Black and dark brown usually took the form of a border what appeared to be a film on the tooth; though it might be more widespread, and the green often seemed to extend the gingival margin towards the incisal edge or cusps.

The percentages of children whose teeth were all free stain were 51.6 in 1943 and 35.5 in 1945. With black and brown stains on some or all of their teeth there were 11.1 and 11.3% and with green stains 34.9% and 46.5% respectively. The teeth of a few children had yellow or lightish-brown stains or a combination of two or more stains, but figures will not be given for them here, as there were too few in any group to be of significance.

It was noticed that many of the children whose teeth showed the black and dark-brown stains were caries-free, and an attempt was made to discover whether the stains were definitely associated with the incidence of caries. Table VIII indicates that in each survey the percentage of carious teeth and the ACF of children with black and dark-brown stains were lower, with green-stains somewhat higher, than those of the children with no stain. It thus seems from these figures that black and dark-brown stains are associated with a lower incidence of dental caries, whereas green stains may be associated with a higher incidence, but we have no knowledge as to the reasons for these apparent associations.

Discussion

An account is given of two investigations on the condition of the deciduous teeth of 5-year-old children attending L.C. schools in 1943 and 1945, and a comparison is made between these investigations and one of a similar nature made by one of us (M. M.) in 1929. Since, however, no data are now available in regard to the state of the individual teeth in 1929, the comparison is confined to the general dental condition. In 1943 this was much better as regards dental structure and caries than in 1929, and in 1945 it was still further improved.

Though the 1943 and 1945 investigations were not controlled in the way that animal experiments can be regulated, the groups of children examined were comparable in that they were of the same age group and social class and resided in the same district of the L.C.C. area. From the dietary point of view there was a degree of similarity during the war years, because the rationing and "points" system of food distribution gave equal purchasing opportunities to all families. The main point of dissimilarity, so far as could be seen, was that the 1929 group of children had been subjected for a longer period to the war dietary than the 1943 group—a fact to which attention must be drawn.

Data obtained from the classification of individual teeth emphasized the better dental condition of the children seen in 1945 as compared with 1943. For instance, the percentage of teeth of good structure (Hy.) rose from 30.7 in 1943 to 38.0 in 1945, and of caries-free teeth (C.) from 69.9 to 73.5. A statistically significant difference in each case—and the percentage of teeth with the more severe defects of structure (M-Hy.) and more advanced caries (C.) decreased appreciably in the intervening period. The amount of arrest or spontaneous "healing" of the carious process was almost twice as great

1945 as in 1943—an indication that some powerful post-ruptive influence had been at work.

If, as seems certain, this improvement in dental condition is of accidental, but is related to some factor or factors of diet or environment to which the children were subjected, an examination of possible factors may bring to light those responsible for the facts observed.

It is claimed by some that carbohydrates play a prominent part in the initiation of caries. Others say that poor dental hygiene is responsible, and yet others that heredity is an important factor. So far as our knowledge goes, however, there is no sound scientific evidence for any of these contentions. To test the carbohydrate theory, King (1946) investigated the effects of nightly supplements of boiled sweets and chocolate-coated biscuits on the deciduous teeth of a small number of infants living in two institutions. The supplements were given when the children had cleaned their teeth just before going to bed. There was no increase in carious activity in the children over periods of from 6 to 24 months, and at the end of the test previously active caries had become arrested. It must be stated that the children had a good calcifying diet containing cod-liver oil. This result does not support the view that carbohydrates are responsible for the disease. The two recent surveys on L.C.C. school-children also do not uphold the theory. Less active caries and a greater proportion of teeth showing arrest of the disease were seen in 1945 than in 1943, but there is no evidence that the consumption of carbohydrates among young children had diminished in the intervening period.

It cannot be argued, either, that the reduction of caries in 1945 as compared with 1943 was in any way related to better dental hygiene, since as the war progressed civilian dentists became fewer and toothbrushes were more difficult to obtain (Majee, 1946).

If heredity were the potent factor in caries that it is sometimes claimed to be we should not see the deterioration in the dental condition of native races that is so evident when they come in close contact with Western peoples. An outstanding example of this is seen in the American negroes who have become completely Westernized in their habits and dietary. It is well known, too, that both children and adults of the primitive races in Africa who adopt the Western mode of life and diet—those, for instance, living for long periods in the ports and industrial areas—lose that freedom from caries which is so common while they remain in their natural habitat, and the same deterioration is seen in Eskimos attached to trading stations. It would seem, therefore, that some other cause for the observed improvement in dental condition in 1945 as compared with 1943 must be sought.

Previous investigations on children by one of us (M. M.) and by colleagues using the same standards (Deverall, Dental Disease Committee, 1936; Davies, 1939; King, 1940) have shown that resistance to caries is related to dental structure *as diagnosed in these surveys*—that is to say, the better the structure the less the liability to decay. Unfortunately this relationship is not always appreciated by dental surgeons, many of whom recognize only the more gross forms of hypoplasia. It has also been shown that the chief factors required for the production of well-formed teeth include a sufficiency of calcium, phosphorus, and vitamins D and A, and that these same factors in the diet after eruption of the teeth tend to retard the onset of caries and to arrest the disease when present. If vitamin D and calcium supplies are deficient other food factors come into prominence. Certain constituents of cereals, for instance, may under these circumstances be harmful from the point of view of the teeth.

During the early stages of dental development mother and child must be considered as one unit. The pregnant and lactating woman must herself then be made as dentally fit as possible to avoid absorption of toxins and to enable her to masticate her food, and her diet must be such that the developing foetus, and later the infant, is supplied with the food factors necessary for the production of well-formed teeth. After weaning, the child itself must continue to receive a calcifying diet.

There is no doubt that in this country the diet of the majority of people, and especially of the children, is far better to-day in this respect than it was, say, 25 years ago. During recent years,

and particularly during the immediate pre-war and the war years, pregnant and nursing women, infants, and children have been encouraged (a) to consume more milk and eggs and so to obtain larger supplies of calcium and phosphorus, as well as of vitamins D and A; (b) to take vitamin D- and vitamin A-containing substances, either as cod-liver oil or as one of the proprietary products; and (c) to eat more potatoes. Moreover, for a number of years now vitamins D and A have been added to some brands of margarine, and since the early days of the war this has been made compulsory for all brands. Again, calcium was added to some flours before the war, and since 1943 the addition has been a routine measure.

It seems probable that the improvement in dental condition of 5-year-old children during recent years is directly related to the enrichment of their diet in these respects. The children examined in 1943 showed a considerable improvement on the 1929 group, and, as has been indicated in the tables in this paper, the 1945 group, who had received calcifying supplements for longer periods than their predecessors in 1943, showed an even greater improvement. Not only were their teeth better formed and less carious, but a greater percentage that had been attacked by caries had set up a resistance, as a result of which the carious process had been arrested. The advantage of this natural "healing" of carious cavities over treatment by filling or extraction is obvious. Evidence is accumulated to show that in some other countries, among them Norway and Sweden, there has been a progressive decrease in caries incidence during the past few years and that it could be attributed to the increased consumption of cod-liver oil, calcium, and vitamin preparations. It is of interest to learn, in view of the controversy on the effect of carbohydrates on the teeth, that in Sweden the amount of chocolate and sugar consumed is high and continued so throughout the war.

Taking all known facts into consideration, therefore, it would seem that nutritional factors offer the most likely solution to the problem of tooth structure and freedom from caries, and it appears to us that the incidence of the disease could be still further reduced by giving diets rich in calcifying properties to everyone, but especially to all pregnant and nursing women and to infants.

It must be borne in mind, however, that in spite of the improvement in dental condition described here, we in this country have not yet gone very far along the road to perfection. There are even to-day over 70% of L.C.C. school-children between the ages of 5 and 6 years who have some decayed deciduous teeth, and there are other parts of the country where the situation is worse. It is evident, therefore, that we still have a long way to go before we can guarantee that a child will grow up without dental decay.

Summary

The dental condition of comparable groups of 5-year-old children attending L.C.C. schools in 1943 and 1945 respectively is described and discussed, and is compared with that found in 1929.

The general dental health of the children examined in 1943 was much better than that of the 1929 group, and in 1945 there was a further appreciable improvement.

The individual teeth in 1945 were significantly better in structure and had less caries than those in 1943.

A point of special significance is that the percentage of carious teeth showing arrest of the disease was almost twice as large in 1945 as in 1943. The percentage of such teeth extracted, treated by silver nitrate, or filled was considerably smaller in the second survey than in the first.

Superficial black or brown stains, which were observed on many teeth, appeared in both surveys to be associated with a lower incidence of caries, and green stains with a somewhat higher incidence, than the absence of stain.

There was in both surveys a relationship between M-hypoplasia and caries, the more severe the degree of structural defect the higher being the incidence of the disease. Teeth with gross hypoplasia showed a medium amount of caries.

It is suggested that the better condition of the teeth of 5-year-old children in 1943 and 1945 as compared with 1929 was due to the increased calcifying properties of the dietary of this country, and particularly of pregnant women, infants, and young children during recent years, and that the improvement observed in 1945 as compared with 1943 was due in the main to the longer period the teeth examined had been influenced by the type of diet made available immediately before and during the war years.

Acknowledgments

Our thanks are extended to many who have helped us directly or indirectly with the investigations and the preparation of this report. We are especially grateful to Mrs. M. Kelley and Miss I. Allen for their assistance with analysis of the results, the compilation of the tables, and the arrangement of the text; also to Dr. W. J. Martin, of the Medical Research Council, for the statistical assessment of some of the figures. Others we would particularly like to mention are the London County Council and Sir W. Allen Daley for their permission to carry out the inspections and for making arrangements for us to visit the schools; the care-committee workers; the medical officers of health and others in the districts we visited who kindly supplied us with much invaluable information; and the head teachers and their assistants, especially those who so willingly allowed us to pay them a second visit.

H. C. held a scholarship from the British Council, and the expenses of the investigations were paid by the Medical Research Council. To both of these bodies we are grateful.

A CASE OF ADDISON'S DISEASE SUCCESSFULLY TREATED BY A GRAFT

BY

L. R. BROSTER, O.B.E., F.R.C.S.
Surgeon to Charing Cross Hospital

AND

H. GARDINER-HILL, M.B.E., M.D., F.R.C.P.
Physician to St. Thomas's Hospital

This is the story of a young woman in whom, nine months previous to our seeing her, a diagnosis of Addison's disease had been made on clinical and biochemical findings. The diagnosis was confirmed at the time of our examination, and one of us (L. R. B.) subsequently ingrafted an adrenal gland from a patient with the adreno-genital syndrome (hyperplasia). As a result of this operation our patient lost her symptoms and signs of Addison's disease, and sodium chloride withdrawal tests showed that her blood sodium no longer fell below normal. The last test (14 months after operation) showed that this change had been maintained; and she was now able to leave off substitution therapy with sodium chloride without relapse.

Case History

Miss W., aged 33 (Jan., 1945), had not been well for six years, the onset of her illness coinciding with the outbreak of war in 1939. There were four groups of symptoms: (1) Depression and nervous symptoms which had been present since the start. For a time she had thought that these were due to the war. (2) Gastro-intestinal symptoms: during the whole period of her illness she had suffered on and off from what she described as a "nervy tummy." She felt that it was on the move all the time and complained of attacks of diarrhoea lasting for two or three days which alternated with bouts of constipation. No evidence of organic disease had been found by Dr. Wetherell, and it would appear that these attacks did represent an irritable gastro-intestinal neuro-muscular mechanism. In April, 1944, an x-ray examination was carried out, but the only abnormality was a spastic descending colon. In May, 1944, she was sent to Sir Arthur Hurst. He discovered that she had achlorhydria, and as a result of the acid therapy which he instituted the attacks of diarrhoea practically disappeared. (3) Extreme lassitude had been noticeable from 1943 onwards, but it had been difficult to assess the relative significance of psychological and physical factors. Dr. Wetherell, in April, 1943, found her blood pressure to be

110/76, and the same level was found by Sir Arthur Hurst at examination at about this time. It was then that Addison's disease was first suspected by Dr. Wetherell and Sir Arthur Hurst. (Pigmentation: a smoky brown pigmentation was first commented on by Dr. Wetherell and Sir Arthur Hurst in April, 1944, and had become more pronounced by the time we saw her in January 1945.

In April, 1944, she was under Sir Arthur Hurst's care at Oxford, and he notified Dr. Wetherell that he agreed with his opinion and that the probable diagnosis was Addison's disease. Increased pigmentation and general asthenia troubled her most; and a low systolic blood pressure, 110, was the chief physical sign. Her blood sodium at this time was 310 mper 100 ml. (the normal level being 320). Sir Arthur Hurst commented that no fall in blood chloride or rise in blood potassium was found, but that neither was a constant feature in early cases. He advised extra salt to the extent of four teaspoonfuls daily, and the patient commented on an immediate improvement, saying that she felt stronger and fitter. Sir Arthur Hurst felt that this might have been due only to suggestion, but the improvement was so marked that he thought it was the direct result of the increased sodium chloride intake and further evidence in favour of Addison's disease. He advised continuation of this treatment.

In October, 1944, the blood sodium level was 284 mg. per 100 ml. The patient was supposed to be on full substitution therapy with sodium chloride, but Dr. Wetherell thought that her ingestion of sodium chloride had been distinctly "sporadic." He subsequently made arrangements for her to see Mr. Broster and she came into University College Hospital private ward under our care in January, 1945.

Other investigations had been carried out. Her blood count on two occasions was normal. No occult blood had been found in her stools, which contained no excess of fatty residue, no inflammatory material, and no pathogenic bacteria. No tubercle bacilli were found. A test-meal showed complete achlorhydria. Her weight in adult life was normally 8 st. (50.1 kg.), and it remained at 8 st. until the spring of 1944. She then lost weight to 7 st. 4 lb. (46 kg.), and has remained at that since. Her menstrual cycle has been regular throughout—5/28-day type.

On examination in January, 1945, when she came under our observation, she had been under treatment with sodium chloride four teaspoonfuls daily, and injections of cortical hormone, but there was still considerable pigmentation of her entire body. There was a smoky brown discoloration of the nipples and in the axillae, and patches of pigmentation on her buccal mucous membrane. Blood pressure at that time was 120/80. There were no abnormal physical signs in her cardiovascular system. Chest and abdomen were normal, as were her secondary sex characters. She was normally developed. Her weight was 7 st. 4 lb. A radiological examination of the abdomen showed a hazy area of calcification over the upper pole of the left kidney which was interpreted by the radiologist as indicating calcification in the adrenal gland on that side. The Mantoux test was negative.

During the first week of her stay in hospital her temperature chart showed a slight and irregular pyrexia up to 99.6° F (37.55° C.), but it never reached 100° (37.8° C.). Subsequently her temperature was normal except for a slight recrudescence of fever for a few days after operation.

To establish the diagnosis of Addison's disease her substitution therapy of salt and cortical hormone was discontinued for a week. At the end of that time her pigmentation and asthenia had definitely increased. Her blood pressure fell at the end of a week off treatment to 95/80. Serum sodium at this time was 295 mg. per 100 ml., and serum potassium 21 mg. per 100 ml. We considered that these findings established the diagnosis of hypocortical adrenalism.

After this sodium withdrawal test she was put back on sodium chloride treatment, and a week later the grafting operation was carried out by L. R. B.

Description of the Donor

Miss H., aged 21, a robust young lady, was first seen in 1942. Her history was that at the age of 16 she began to

develop hirsuties, but except for a bout of amenorrhoea for three months her periods had been normal. Her ketosteroid excretion was 15 mg. a day, and she was treated medically for adrenal virilism, Group II.

She then joined the A.T.S. and became a P.T. instructress. The hirsuties became worse, and she shaved daily; there was amenorrhoea for three months; she broke off her engagement. She reported again at the end of 1944 and her ketosteroid excretion was now 29.5 mg. a day. During her stay in hospital in February, 1945, she was mildly hallucinated, depressed, and uncooperative, and although a month after the operation described below her ketosteroid excretion dropped to 5 mg. a day, contrary to our previous experience her mental condition deteriorated considerably and remained so longer than usual. The details of her psychosis were observed by Dr. Clifford Allen.

Operative Procedures

Donor.—On Feb. 13, 1945, the left adrenal gland was removed at the Charing Cross Hospital. It was an ideal one—hypertrophied to two to three times the normal size. Its vein, unbranched and large, was cut long so as to leave about 1/2 in. (1.27 cm.) attached to the gland. The vein was perfused with heparin solution, and the graft placed in normal saline in a sterile glass container. This was then put into a second sterile glass container and transferred to a vacuum flask at body heat.

Recipient.—The recipient was prepared in the private wing of University College Hospital. An incision was made along the outer border of the left rectus muscle, the rectus retracted inwards, and 1 in. (2.54 cm.) of the deep epigastric artery and vein was exposed and cut medially. Arterial bleeding was

Figs. 1, 2, and 3. A=Hilum; B=Adrenal gland, lobulated; C=Main adrenal vein; D=Retractor; E=Rectus muscle; F=Rectus sheath; G=Divided rectus; H=Deep epigastric artery; I=Deep epigastric vein; J=Extraperitoneal fat; K=Ligature, with knot pulling up vein; L=Adrenal gland; M=Ligature, with knot pulling up artery; N=Adrenal vein, containing artery and vein; P=Stitch separating artery and vein.

controlled by finger pressure, and the wound was bathed in heparin solution. The artery and vein were each caught up laterally by a stitch of the finest catgut threaded on two straight needles. By this time bleeding had ceased. The artery and then the vein were separately piloted into the

adrenal vein by pushing the two needles up the latter and causing them to emerge at separate points on the surface of the gland. The vessels were anchored in position by tying the stitch across the intervening cortex. To prevent any backflow of blood a stitch was tied across the open end of the adrenal vein, dividing the epigastric artery and vein into two separate compartments (see Figs. 2 and 3). The graft lay snugly in the extraperitoneal fat when placed behind the rectus muscle. Including the journey by car, the whole operation took about three-quarters of an hour. The wound healed by first intention.

Convalescence

On the second day after the operation the recipient menstruated unexpectedly for three days—twenty-four hours before the donor, who started again normally after three months' amenorrhoea. The recipient now took her rhythm from the donor, and the next period came on March 18, 1945, and lasted five days. The day before this period, "she felt the graft enlarged and never felt so well." The day after, she experienced soreness and burning in the left abdomen, and developed a haematoma which subsided normally. It was obvious that the vascular anastomosis of the graft had leaked and could not cope with the extra flow of blood induced by the general pelvic congestion.

It was feared that this unforeseen occurrence due to a normal physiological function had jeopardized the vitality of the graft. However, during subsequent examinations the graft, though smaller, was palpable and tender, more so just before and during a period, and on deep pressure pain was referred towards the left subcostal margin.

She continued on salt treatment during her convalescence, and three weeks after the operation she was discharged from hospital: blood pressure 115/85; serum sodium 333 mg. per 100 ml.; serum potassium 21 mg. per 100 ml. Her pigmentation had definitely decreased. As she was on substitution therapy it was obviously not possible to assess the effects of the graft, and in view of her psychological state we did not think it advisable to perform a sodium withdrawal test at this time. It was agreed that she should return to hospital for this to be carried out.

She returned to her home but had to be readmitted to hospital three and a half weeks later for the above haematoma, which quietly subsided. Her serum sodium at this time was 300 mg. per 100 ml.; serum potassium 33 mg. per 100 ml.

Sodium Withdrawal Tests

(1) Sodium withdrawal test three months after operation.—On admission her general health had improved, but the report from her home was that she had not been doing anything at all and had only been up for an hour or two a day. She had continued on sodium chloride, four teaspoonfuls daily, and it seemed to be her psychological state which prevented her from doing more. She appeared to have a considerable anxiety state, which perhaps was not surprising after her long illness.

On examination, her pigmentation was much less evident; blood pressure 115/75; serum sodium 325 mg. per 100 ml.; serum potassium 23 mg. per 100 ml.

She was left off salt treatment for seven days without any deterioration in her general condition. At the end of seven days her blood pressure was found to be at about the same level—112/70; serum sodium was 340 mg. per 100 ml.; serum potassium 21 mg. per 100 ml. This was obviously a great improvement as compared with the sodium withdrawal test before operation.

It was decided that she should return home and continue with sodium chloride, four teaspoonfuls daily, and get up and about and lead as normal a life as she could.

(2) Second test, nine months after operation (November, 1945).—Her general condition, mental and physical, had much improved. In fact, we noted a particularly striking psychological improvement. Her general pigmentation was very slight, and there was no pigmentation on her buccal mucous membrane. Her blood pressure on admission was 130/95; serum sodium 310 mg. per 100 ml.

Sodium chloride treatment was left off for eight days, and at the end of that time her blood pressure was 120/95. Her serum sodium had risen to 365 mg. per 100 ml. This reading was doubted, so a second serum sodium examination was carried out a few days later to confirm, and a level of 340 mg. per 100 ml. was found. It should be mentioned that a menstrual period coincided with this test, the losses starting two days after salt had been withdrawn.

She was again sent home to lead as normal a life as possible, and this time it was clear that she had developed more confidence.

(3) The third test, thirteen months after operation (February, 1946).—There was a striking improvement in her general physical and mental condition. She was still emotionally unstable, as was shown not only by her subjective complaints but also by the wide variations in the blood pressure readings found on admission. There were pronounced peaks, but the average was 145/80. Her serum sodium on admission was 335 mg. per 100 ml.; serum potassium 20.5 mg. per 100 ml.

This sodium withdrawal test was carried out over seven days, and at the end of this time there was no deterioration in her general condition; blood pressure readings averaged 155/100. Her serum sodium was 330 mg. per 100 ml., her serum potassium 20 mg. per 100 ml. At the end of the test the sodium chloride treatment was restarted and continued for seven days, after which serum sodium was 336 mg. per 100 ml.; serum potassium 23 mg. per 100 ml.

It was then decided that she should leave off substitution therapy with sodium chloride altogether and return to a normal diet. This she did for the remainder of her stay in hospital—nineteen days—and at the end of that time her average blood pressure readings were 155/110, with even more pronounced emotional reaction peaks. In fact, on one occasion a systolic pressure of 180 was registered while she was complaining of sensations of what she described as "whizziness." Serum sodium figure before she left hospital was 335 mg. per 100 ml.; and serum potassium 21 mg. per 100 ml. It should be mentioned that a menstrual period again occurred during the first week of this last stage, when she was off salt treatment altogether. She was discharged home to lead a normal life. Since her discharge she has had no substitution treatment with salt or cortical hormone and has been leading as normal a life as is consistent with her psychological condition. She is obviously much improved, and there can be little doubt that the sodium withdrawal tests show that her cortical deficiency has been controlled by the grafting operation.

Table Summarizing Effects of Treatment

(1) Jan. 25, 1945–March 5, 1945 (5½ weeks):			
On admission	B.P.	120/80
Off salt 7 days	B.P.	95/80
		Na	295
		K	21
On salt 25 days	B.P.	115/85
(Operation after 8 days)		Na	333
		K	21
(2) March 30, 1945–April 5, 1945 (6 days):			
Admitted for haematoma	B.P.	—
		Na	300
		K	33
(3) May 11, 1945–May 29, 1945 (18 days):			
On admission	B.P.	115/75
		Na	325
		K	23
Off salt 7 days	B.P.	112/70
		Na	340
		K	21
(4) Oct. 22, 1945–Nov. 9, 1945 (18 days):			
On admission	B.P.	130/95
		Na	310
Off salt 8 days	B.P.	120/95
		Na	365 (2nd exam. to confirm = 340 a few days later)
(Menstrual period coincided, starting 2 days after salt withdrawal begun)			
(5) Feb. 25, 1946–April 3, 1946 (5½ weeks):			
On admission	B.P.	145/80
		Na	335
		K	20.5
Off salt 7 days	B.P.	155/100
		Na	330
		K	20
On salt 7 days	Na	340 (duplicate readings)
		K	23
Off salt altogether 19 days	B.P.	155/110 (with emotional peaks + + to 180 and feelings of "whizziness")
		Na	335
		K	21
(Menstrual period for first 7 days)			

The Donor.—When seen in June, 1946, she had made satisfactory psychosomatic recovery except for slight hirsuties.

Discussion

The diagnosis of Addison's disease in this girl was based on the classic clinical picture—typical asthenia, pigmentary gastro-intestinal symptoms, and low blood pressure. When originally came under Dr. Wetherell's observation for condition her blood sodium was 310 mg. per 100 ml.; months later it had fallen to 284 mg. per 100 ml. When came under our observation three months later she was taking extra salt and was on substitution therapy; an initial sodium withdrawal test for a week resulted in her blood sodium falling to 295 mg. per 100 ml., and her blood pressure to 95 systolic. We considered that the diagnosis of Addison's disease was established.

The patient's condition changed satisfactorily after operation and, in our opinion, as a result of it. Sodium withdrawal test carried out for a week at a time at intervals as above showed that she no longer reacted to withdrawal of extra salt by a fall in blood sodium or a fall in blood pressure. In the first two sodium withdrawal tests in May and October, four and nine months after the operation, the blood sodium rose rather than fell at the end of the week's extra salt withdrawal, while the blood pressure remained at about the same level. In the final test, just over a year after operation, blood sodium remained at a steady level after extra salt withdrawal, and the blood pressure was slightly higher at the end of this week's test. The results of these tests were obviously entirely different from the results of the tests before operation and we felt it reasonable to assume that the cortical deficiency had been corrected. This was confirmed by the fact that following the final test the patient was able to leave off extra salt and carry on without any treatment at all. The last blood sodium reading, after three weeks off all treatment, was within the normal limits, while her blood pressure at this time was actually showing readings that had never been recorded before. As a result of what we considered to be emotional reaction when her blood pressure was taken, readings as high as 180 systolic were found.

The results, therefore, of the grafting operation appear to have been extremely satisfactory, and if one can accept blood sodium levels in similar salt withdrawal tests before and after operation as an indirect indication of the state of the cortical-deficiency sodium leak it would appear that the leak has been compensated by the adrenal graft. It was unfortunately impossible to get the measure of the leak by urinary sodium and chloride excretion estimations, but it would certainly have been interesting to have noted whether there was a raising of the renal threshold during the tests as an explanation of the high sodium figures noted after the second and third tests.

Further follow-up data will be published in due course, but as it is now over a year from the time of the operation we are hoping that the improvement will be maintained.

It is to be noted that in spite of the fact that this patient was grafted with an adrenal from a patient with the adrenogenital syndrome there is no evidence of that condition developing in her case, and her menstrual cycle remained regular throughout the period of observation following operation. H₁₇-ketosteroids were estimated about two months after the operation and found to be within the normal range—10.3 mg. a day.

Summary

An account of a patient with Addison's disease is given. The grafting into this patient of a hypertrophied adrenal gland derived from a woman suffering from the adrenogenital syndrome (hyperplasia) is described.

Sodium chloride withdrawal tests indicated that the improvement in the patient's condition was due to the operation, and in particular that the blood sodium no longer fell below normal when the patient was taken off sodium chloride substitution therapy.

Cure has been maintained until the present time—fourteen months after operation.

LYMPHOCYTIC CHORIOMENINGITIS

BY

B. R. SREENIVASAN, L.M.S.Singapore

1910 Laubry and Foy described three cases of this disease, curring in Paris, under the heading of "syndrome méningéal ec lymphocyte fuchidienne d'origine indéterminée," and ist and Rolland (1910) five cases of a similar condition as méningite bénigne d'allure épidémique." In 1925 Wallgren, a paper entitled "A New Infectious Disease of the Central ervous System," reported a Swedish epidemic of 19 cases.

Gibbens (1931) termed it "acute aseptic meningitis," and scribed the following characteristics of the condition: (1) a acute onset, with definite meningeal signs. (2) Meningeal anges in the cerebrospinal fluid; there is an increase of essure and of cells, but the fluid is sterile on culture. (3) uniform clinical symptomatology. (4) A relatively short nign course without secondary complications. (5) No idemiological connexion with any known infectious menin- al disease. (6) There is no local infection such as otitis edia or sinusitis.

Although it has been suggested that some of the cases de- scribed under various headings, such as "benign lymphocytic eningitis," "acute aseptic meningitis," and "lymphocytic oriomeningitis," have been really cases of lethargic enceph- tis or poliomyelitis, it is now generally conceded that there a disease *sui generis*, which is best termed "lymphocytic horiomeningitis."

Clinical Features.—The clinical features of the disease are as ollows. The onset is acute, with fever, headache, and eningeal signs. The cerebrospinal fluid is clear or turbid; nder increased pressure, and shows a pleocytosis varying from 0 to 1,500 per c.mm.; polymorphonuclears may predominate t the onset, but are rapidly replaced by lymphocytes; the total rotein and globulin are increased, the sugar and chlorides usually being unaffected; the fluid is sterile on culture, and irect smears are negative for all organisms, including the ublicle bacillus. The prognosis is good, complete recovery ccurring in two or three weeks as a rule.

Aetiology

Armstrong and Lillie (1934) isolated a virus from a case that appeared clinically to be encephalitis lethargica (St. Louis type). It differed from the virus of encephalitis, however, in the ollowing characteristics:

(a) It was not pathogenic for rabbits.

(b) On intracerebral inoculation into mice the animals developed symptoms which are quite different from those produced by encephalitis. The incubation period was 6 to 7 days and fairly constant. "When lifted up by the tail a series of rapid jerky motions with the front and hind legs results, which conveys a pronounced sensation of tremor to the hand, readily distinguishable from that observed with normal mice. These rapid motions often pass into a convulsion, lasting from some seconds to a minute or more, in which the hind legs and toes are strongly extended and rigid, as is also the tail. The seizure may end in death or gradually relax, when the mouse may run about the cage apparently normal. Practically all the mice, however, ultimately die in convulsions, usually in from 1 to 3 days from the onset of symptoms."

(c) On post-mortem examination the mice showed marked cellular infiltration of the meninges, in which lymphocytes predominated, more pronounced on the base of the cerebrum and in the space between the hippocampus and the brain-stem. Also there is often a lymphocytic infiltration of the choroid plexus. No cellular gliosis is seen around the vessel sheaths as in encephalitis.

(d) In monkeys inoculated intracerebrally with the virus it is found to be present in the blood and cerebrospinal fluid.

(e) Intranasal inoculation has no effect.

(f) Cross-neutralization tests indicate that the two viruses are immunologically distinct.

More recently Findlay, Alcock, and Stern (1936) have isolated a virus from cases that correspond clinically with the picture of lymphocytic choriomeningitis and have shown this virus to

be identical with that obtained by Armstrong and Lillie, thus establishing the aetiology of the disease.

Pathology

Viets and Warren (1937) have given the post-mortem findings in one of their cases. The report is here summarized:

The meninges were oedematous, congested, and infiltrated mainly with lymphocytes and also a few endothelial cells. The cerebrum showed a localized oedema of the cortex just below the surface. Perivascular infiltration with lymphocytes and endothelial cells was present. Other cells resembling microglia and a few large cells four or five times the diameter of the lymphocytes with somewhat acidophilic cytoplasm and eccentric, large, and indefinite nuclei were observed. No inclusion bodies were seen. In the midbrain the changes noted were even more evident; in addition, in numerous swollen ganglion cells cytoplasmic inclusion bodies were seen, some of them being rod-like in shape and others round. In the internal capsule the reaction was less intense and no inclusion bodies were found. In the cerebellum and spinal cord perivascular infiltration and gliosis in the white matter were seen and there were no inclusion bodies.

Case Records

Hughes (1937) states that cases have occurred in Asiatics, but does not describe any. Below are recorded eight fairly typical cases that have been under my care in the third-class male wards of the General Hospital, Singapore. My colleagues and I have seen several other cases at the hospital.

Case 1.—A male Malabari Indian aged 21 was admitted on Oct. 6, 1938, with a history of fever for five days. No further history was obtainable. He was delirious on admission, being quite uncontrollable, and had to be kept under the influence of morphine and hyosine. The neck was not rigid, and Kernig's sign was negative. There was no evidence of involvement of the cranial nerves or paralysis of the limbs. The temperature on admission was 103° F. (39.4° C.); it came down to normal on Oct. 9, but showed an occasional rise up to 100° F. (37.8° C.) from time to time. The ear-nose-and-throat examination was negative, and the fundi were normal. The blood Kahn test was negative (000). The cerebrospinal fluid showed the following changes: pressure increased, naked-eye appearance turbid; cell count, 542 per c.mm. (polymorphonuclears 65%, lymphocytes 35%); total protein, 80 mg. per 100 ml.; globulin + (Ross-Jones); sugar, 51 mg. per 100 ml.; chlorides, 660 mg. per 100 ml.; W.R. negative, Kahn test negative; direct smears negative for organisms (including T.B.); culture sterile; no clot on standing. On Oct. 11 the cerebrospinal fluid was clear; the cell count was 100 (polymorphonuclears 5%, lymphocytes 95%). On Oct. 23 the cerebrospinal fluid was clear, the cell count being 60 (polymorphonuclears 8%, lymphocytes 92%). The patient was discharged cured on Oct. 28.

Case 2.—A male Hokien aged 19 was admitted on Oct. 31, 1938, with a history of fever, headache, and a feeling of chilliness not amounting to a rigor, for one week. The temperature on admission was 101° F. (38.3° C.). On physical examination no abnormality was found except slight stiffness of the neck and a positive Kernig's sign. Examination of the central nervous system was normal. A lumbar puncture was done on Nov. 1, and the cerebrospinal fluid showed the following changes: cell count, 152 per c.mm. (polymorphonuclears 35%, lymphocytes 65%); total protein, 250 mg. per 100 ml.; globulin + (Ross-Jones); sugar, 10 mg. per 100 ml.; chlorides, 627 mg. per 100 ml.; direct smears negative for organisms (including T.B.); culture sterile; no clot on standing; W.R. negative, Kahn test negative. The blood Kahn test was negative (000), the fundi were normal, and the Mantoux test was positive. Lumbar puncture was repeated almost every day for the relief of headache, and a precipitin test done on the cerebrospinal fluid against the meningococcus was negative. On Nov. 7 the cell count was 155 per c.mm. and all the cells were lymphocytes. On Nov. 16 the cell count was 35 per c.mm., all the cells being lymphocytes; total protein, 150 mg. per 100 ml.; and there was no globulin (Ross-Jones). This man was discharged against medical advice, improved but not cured.

Case 3.—A male Tamil aged 22 was admitted on April 6, 1941, with a history of fever, weakness of the legs, and giddiness for two days. On admission the temperature was 101° F. (38.3° C.), there was rigidity of the neck, and Kernig's sign was positive. Examination of the central nervous system revealed no abnormality. A lumbar puncture was done on April 7, the cerebrospinal fluid showing the following changes: cell count, 900 per c.mm. (polymorphonuclears 4%, lymphocytes 96%); globulin + (Ross-Jones); total protein, 125 mg. per 100 ml.; sugar, 47 mg. per 100 ml.; chlorides, 745 mg. per 100 ml.; direct smears negative for T.B. and other organisms; culture sterile; no clot on standing; W.R. negative. On April 16 the cell count was 22 per c.mm., the total protein 50 mg. per 100 ml., and there was only a trace of globulin. The

fundi were normal, and the blood Kahn test was negative (000); the total white count, was 7,500 per c.mm. (polymorphonuclears 60%, lymphocytes 36%, and large hyalines 4%). The patient was treated with repeated lumbar punctures and sulphanilamide 1 g. t.d.s. from April 9 to 15. The temperature came down on April 10 and remained normal. The patient was discharged cured on April 19 and returned to work on May 3.

Case 4.—A male Tamil aged 32 was admitted on April 22, 1941, with a history of fever, headache, and vomiting for one week. The temperature on admission was 103° F. (39.4° C.); the patient was drowsy and difficult to examine. There was neck rigidity, but Kernig's sign was negative. A complete examination of the central nervous system revealed no abnormality. A lumbar puncture was done on the day of admission, when the cerebrospinal fluid showed the following changes: naked-eye appearance, granular-looking; cell count, 206 per c.mm. (polymorphonuclears 18%, lymphocytes 82%); total protein, 70 mg. per 100 ml.; globulin + (Ross-Jones); sugar, 84 mg. per 100 ml.; chlorides, 705 mg. per 100 ml.; direct smears negative for T.B. and other organisms; culture sterile; no clot on standing; W.R. negative, Kahn test negative. The blood picture was as follows: total red cells, 5,700,000 per c.mm.; haemoglobin, 100% (Sahli); total white cells, 15,000 per c.mm. (polymorphonuclears 79%, lymphocytes 17%, large hyalines 3%, eosinophils 1%). The blood Kahn test was negative (000) and the fundi were normal. On April 29 the cell count in the cerebrospinal fluid was 50 per c.mm., 10% being polymorphonuclears and 90% lymphocytes. The patient was treated with sulphanilamide 1 g. t.d.s. from April 22 to 29. The temperature came down to normal on the 26th and remained so. The patient was discharged cured on May 3.

Case 5.—A male Hokien aged 26 was admitted on July 5, 1937, with headache and vomiting for three weeks. He gave a history of exposure to venereal infection on June 5 and had developed a urethral discharge and buboes on both groins on June 14. Clinically the case was one of lymphogranuloma inguinale, and Frei's intradermal reaction was positive. The blood Kahn test was negative. It was at first considered that the headache and vomiting were due to toxæmia resulting from the buboes. On July 12 the patient still complained of headache, and on examination there were stiffness of the neck and generalized hyperæsthesia. Kernig's sign was negative, and examination of the central nervous system revealed no abnormality. Lumbar puncture showed the following changes in the cerebrospinal fluid: pressure, 70 mm.—no change on compression of the neck veins; colour, yellow; cell count, 220 per c.mm., all the cells being lymphocytes; total protein, 550 mg. per 100 ml.; globulin ++ (Ross-Jones); sugar +; no clot on standing; culture sterile; direct smears negative for T.B. and other organisms. On July 13, on cisternal puncture, the cerebrospinal fluid showed the following changes: pressure, 40 mm. (on jugular compression it rose to 100 mm.); naked-eye appearance, slightly turbid, almost milky; cell count, 290 per c.mm.; total protein, 90 mg. per 100 ml.; globulin + (Ross-Jones); sugar +; chlorides, 675 mg. per 100 ml. There was no clot, and direct smears were negative for T.B. and other organisms. On July 15 lumbar puncture was repeated. The pressure was 140 mm., there being no change on jugular compression; the cell count was 680 per c.mm., all the cells being lymphocytes. By this time the general condition was improved and the buboes had subsided. There was a slight rise of temperature (up to 100° F. (37.8° C.)) from July 14 to 19, the course of the disease being otherwise afebrile. On the 21st slight headache and giddiness were still present, but there was no vomiting, the neck was not rigid, and Kernig's sign was negative. Repeated lumbar and cisternal punctures were performed, and on July 29 a block was still found. The total white count was 6,800 per c.mm. (polymorphonuclears 70%, lymphocytes 22%, large hyalines 5% eosinophils 3%). The W.R. of the cerebrospinal fluid was negative, and the colloidal gold test was also negative (0000000000). The patient was discharged against medical advice on Aug. 3, but was examined again on Aug. 10 and found to be free from all symptoms. Inquiries carried out several months later revealed that the patient had continued to be fit and was carrying on a normal life.

Case 6.—A male Cantonese aged 42 was admitted on Oct. 19, 1938, with a history of fever, headache, and pain in the bones for four days. Physical examination, including the central nervous system, revealed no abnormality; there was no rigidity of the neck and Kernig's sign was negative. As several cases of lymphocytic choriomeningitis had been encountered at this time, and as some of them had evinced few or no pointers to meningeal affection, a lumbar puncture was done, though neck rigidity and Kernig's sign were absent on repeated examination. The cerebrospinal fluid showed the following: pressure not increased; naked-eye appearance clear; cell count, 563 per c.mm., practically all the cells being lymphocytes; total protein, 120 mg. per 100 ml.; globulin + (Ross-Jones); direct smears negative to T.B. and other organisms; culture sterile; W.R. negative, Kahn test negative. On Oct. 29 slight congestion of the pharynx was noticed. On the 31st lumbar puncture was repeated, with the following findings in the cerebrospinal fluid: naked-eye appearance clear; chlorides, 643 mg. per 100 ml.; sugar

51 mg. per 100 ml.; direct smears, no T.B. or other organisms; all the cells were lymphocytes; culture sterile; precipitin test for meningococci, negative. The Widal and Weil-Felix reactions were negative, and the blood culture was sterile; examination of the ear, nose, and throat revealed nothing abnormal except a deflected nasal septum; the Kahn test on the blood was positive (444). There was irregular fever between Oct. 19 and Nov. 3, after which date the temperature remained normal. The total white count was 7,600 per c.mm. (polymorphonuclears 60%, lymphocytes 40%). The patient was given sulphanilamide 1 g. t.d.s. from Nov. 2 to 9. He was discharged cured on Nov. 9.

Case 7.—A male Tamil aged 23 was admitted on Oct. 22, 1938, with fever and stiffness of the neck for seven days but no headache. There was rigidity of the neck, but Kernig's sign was negative. Examination of the ear, nose, and throat revealed opacity of the antra on transillumination, but skiagrams showed no abnormality; the ethmoid cells were unusually large and numerous. The central nervous system was normal. The fundi were also normal. The blood Kahn test was positive (444). The temperature was 102° F. (38.9° C.) on admission, and there was irregular fever till Oct. 26, after which date the temperature remained normal. On Oct. 23 the cerebrospinal fluid showed the following changes: pressure increased (on jugular compression there was a definite increase); naked-eye appearance slightly turbid; cell count, 831 per c.mm. (polymorphonuclears 90%, lymphocytes 10%); total protein, 150 mg. per 100 ml.; globulin + (Ross-Jones); sugar, 11 mg. per 100 ml.; chlorides, 643 mg. per 100 ml.; W.R. negative, Kahn test negative; direct smears negative for T.B. and other organisms; culture sterile; no clot on standing. On Oct. 27 the cerebrospinal fluid was sterile on culture; the precipitin test for the meningococcus was negative; the cell count was 576 per c.mm., 6% being polymorphonuclears and 94% lymphocytes. The patient 1 g. t.d.s. from Oct. 24 to Nov. 2, and was 1.9.

Case 8.—A male Tamil aged 30 was admitted on April 17, 1941, with a history of vertigo for two days. There were no other symptoms; the ear, nose, and throat were normal, the neck was not rigid, and Kernig's sign was negative. On standing or walking there was a tendency to fall to either side; this did not increase on closing the eyes. Otherwise, examination of the central nervous system revealed no abnormality. The blood picture was as follows: total red cells, 4,850,000 per c.mm.; haemoglobin, 83% (Sahli); total white cells, 6,800 per c.mm. (polymorphonuclears 60%, lymphocytes 18%, large hyalines 2%, eosinophils 20%). There were acystoma ova in the stools. Blood: April 18—W.R. ±, Kahn test ± (111); April 24—Kahn test + (333); April 30—W.R. +, Kahn test + (344). On April 21 the cerebrospinal fluid showed the following changes: naked-eye appearance slightly turbid; cell count, 280 per c.mm. (polymorphonuclears 94%, lymphocytes 6%); total protein, 75 mg. per 100 ml.; globulin + (Ross-Jones); sugar, 57 mg. per 100 ml.; chlorides, 715 mg. per 100 ml.; direct smears negative for T.B. and other organisms; culture sterile; no clot on standing; W.R. negative. On May 5 the cell count was 20 per c.mm., all the cells being lymphocytes. The patient was given sulphanilamide 1 g. t.d.s. from April 22 to 27, and was discharged cured on May 5.

Remarks

Case 5 was complicated by lymphogranuloma inguinale, and though one case of meningo-encephalitis (Rajam, 1936) has been described in this disease, the features of the present case seem to correspond to lymphocytic choriomeningitis rather than to meningitis of lymphogranulomatous origin. The only case of meningo-encephalitis recorded (referred to above) was accompanied by coma, fits, a temperature of 104.4° F. (40.2° C.), and proved fatal; the cerebrospinal fluid showed 90% of polymorphonuclears.

Cases 6, 7, and 8 had a positive blood Kahn reaction; but in my mind there is no doubt that these were cases of lymphocytic choriomeningitis and not syphilitic meningitis, in view of the following facts: (a) The histories were short; otherwise the clinical picture was typical of lymphocytic choriomeningitis. (b) The cases showed clinical cure without any antisyphilitic treatment. (c) The W.R. was negative in the cerebrospinal fluid in all those three cases; this is a very unusual finding in meningeal syphilis. In fact, I have seen hundreds of cases of meningeal syphilis and have never encountered one with a negative W.R. in the cerebrospinal fluid. (d) In Cases 7 and 8 the cell picture showed 90% and 94% of polymorphonuclears, respectively, on the first examination, and subsequently became predominantly lymphocytic. This is typical of lymphocytic choriomeningitis. A marked preponderance of polymorphonuclears is never found in meningeal syphilis at any time. (e) In Cases 7 and 8 there was a marked drop in the cell count in the cerebrospinal fluid without any antisyphilitic treatment.

Findings

Findings may be briefly summarized as follows:

Duration of illness: 2 to 21 days (average 7).

Age incidence: 5 Indians, 3 Chinese.

Sex incidence: 19 to 42 years (average 27). It must be noted here that only adults, as a rule, were admitted to these

Number of days in hospital: 11 to 29 (average 19).

Fever: present in 6 cases.

Headache: present in 4 cases.

Giddiness: present in 2 cases.

Vomiting: present in 1 case.

Weakness of legs: present in 1 case.

Mental symptoms: present in 2 cases.

Hyperaesthesia: present in 1 case.

Neck rigidity: present in 5 cases.

Kernig's sign: positive in 2 cases.

Cerebrospinal fluid: (a) Cell count varied from 152 to 900 per c.mm. (b) Sugar varied from 10 to 84 mg. per 100 ml. 5 out of 6 cases were between 45 and 60 mg. per 100 ml. (c) Chlorides from 627 to 745 mg. per 100 ml.

Cases not treated with sulphanilamide spent an average of 22 days in hospital, whereas those treated with it stayed there for an average of 16 days. From these figures it is impossible to draw any conclusion as to the therapeutic value of sulphanilamide. The clinical impression was that cases seemed to benefit from it.

Conclusions

Lymphocytic choriomeningitis is a disease that occurs not only in Singapore, and, unless one is on the lookout for it, cases might easily be missed. Headache was complained of in only 4 cases and neck rigidity in but 5 out of 8; only 2 had a positive Kernig's sign. In 5 of the cases was simply a pyrexia of unknown origin, and in 3 was no symptom or sign pointing to the central nervous system; this case would certainly have been missed if a lumbar puncture had not been done. It would therefore be advisable to have this disease in mind when dealing with any obscure fever with fever, headache, giddiness, or vomiting. There was no history of a similar illness occurring in the household or among contacts of these cases; none of them showed any evidence of infection of the ear, nose, or throat; and there were no sequelae.

Summary

A brief account of the literature on lymphocytic choriomeningitis is given, with reference to the clinical picture, aetiology, and the history of the condition.

No cases have so far been actually reported in Asiatics, 8 cases of the disease are described.

All the cases were seen at the General Hospital, Singapore.

All the cases conformed to the characteristics described by Gibbens (1931).

There was no death, and no sequelae occurred.

A warning is given that unless one keeps on the lookout for such cases they might be missed.

I wish to thank the ear-nose-and-throat department of the General Hospital, Singapore, for the examination of these cases, and the pathology department, Singapore, for the reports (cultures, W.R. tests, and precipitin tests). I am greatly indebted to Dr. J. V. Forster, physician, General Hospital, for his invaluable advice, and to the Director of Medical Services, Straits Settlements, for permission to publish.

PATHOGENICITY OF GROUP C (LANCIEFIELD)
HAEMOLYTIC STREPTOCOCCUS

BY

R. IRENE HUTCHINSON, M.B., D.P.H., D.T.M.

Emergency Public Health Laboratory Service

Until recently it was believed that Group C (Lancefield) haemolytic streptococci were not frequent in human disease (Evans, 1944), and that when they did occur mild infections only were produced. Harper and Williams (1944), in reviewing the frequency of streptococci in the healthy nose and throat, found them in about 47% of their cultures, and of these only 1.6% belonged to the Lancefield Group C. The Cardiff Public Health Laboratory (1943), analysing the pathogens from acute cases of upper respiratory infection, found Group C streptococci in 7.2%. In a summary of cases of puerperal infection associated with streptococci that were not Group A, Ramsay and Gillespie (1941) reported 12 in which the Lancefield Group C was found. The pyrexia was mild and the infection low-grade. Cases have, however, recently been reported in which these streptococci were associated with severe infections. Thus Portnoy and Reitler (1944) isolated such an organism in an outbreak of acute cellulitis in which 27 people were affected and 4 died. Fatal puerperal infection has also been recorded (Rosenthal and Stone, 1940).

During a period of two years in a very small Public Health Laboratory 105 strains of Group C haemolytic streptococci were isolated. They came from cases of disease and from routine swabbings of maternity staffs and patients and of children in residential nurseries. The comparative frequency of this group compared with the other Lancefield groups isolated during the same period (to a total of 970) was as follows: Group A, 618 cases; Group B, 69; Group C, 105; Group D, 71; Group G, 107. It will therefore be seen that the occurrence is approximately one-sixth of that of the Lancefield Group A streptococcus—frequent enough, if they are pathogenic, to warrant consideration.

Distribution of Group C Streptococci

Of these 105 strains 32 were found in routine swabbings of throats and 4 in routine vaginal swabbings of pregnant women. In these cases they appeared to be saprophytic. The remaining 69 strains originated as follows: Acutely ill cases, 9; mild tonsillitis, 33; suppuration of soft tissues, 12; puerperal genital tract, 12; sputum (chronic bronchitis), 3.

Analysis of Cases.—The most acutely ill case was that of a middle-aged man who developed bronchitis which led within 10 days to a basal pneumonia with pleural effusion. A severe toxæmia, swinging temperature, and tympanites later set in, and suggested a typhoid or other septicaemia. The blood culture yielded a Group C haemolytic streptococcus. Recovery ensued with penicillin therapy. One case of severe cellulitis occurred after a septic soft-tissue lesion. Infection spread down to the bone, and amputation of the terminal phalanx had to be performed. A dental abscess resulting in osteomyelitis of the zygoma also yielded a pure growth of haemolytic streptococci of Group C.

Six of the strains came from septic throats, in which the patient was very ill with a raised temperature, enlarged glands, and sloughing foul necrotic debris on the tonsils. Swabs were sent in for differential diagnosis between Vincent's angina and diphtheria. Neither of these was present, but an almost pure culture of Group C haemolytic streptococci was obtained in each case. It is interesting that the somewhat large number of cases of mild tonsillitis came from widely separated sources from general practitioners who had been consulted with a complaint of sore throat. The presence of a congested red throat and lack of any membrane or debris were always noted. No other pathogenic organisms were present in any of these cases, so that the Group C streptococcus was held to be responsible.

The 12 strains from soft-tissue lesions were from cellulitis, gunshot wounds, abscesses, and ulcers. A Group C streptococcus was the only organism present, except in the case of the gunshot wounds and ulcers of leg. In these a mixed flora of

Staph. aureus (coagulase-positive), coliform bacilli, *Ps. pyocyaneus*, etc., was present. In no case was the patient acutely ill. Three of these 12 cases were associated with purulent discharges. Two were from vaginal swabs from an infant of a few months and a child of about 6 years, respectively. In neither case was any other pathogenic organism isolated, and although the children were not acutely ill they were definitely off colour and the local vaginal area and vulva showed much inflammation. The third case was that of a child with a copious purulent nasal discharge. The patient was suspected of being a chronic diphtheria carrier because of this discharge, but repeated examinations failed to isolate *C. diphtheriae* and always produced the Group C streptococcus.

Of the puerperal cases from which Group C streptococci were isolated from the genital tract, 5 were normal deliveries and the streptococcus was found solely as the result of routine swabbings. They caused no symptoms, and the puerperium was uneventful in each case. In 4 other cases with forceps delivery and extensive lacerations temperatures of from 99.8 to 101.8° F. (37.7 to 38.8° C.) were recorded and sustained for two to three days. Offensive lochia and uterine tenderness were noted. Rapid improvement and complete recovery followed sulphonamide therapy. In one of these the streptococcus was isolated from the throat and vagina before labour started; the other 3 had negative swabs on admission. Two patients after a normal delivery developed a mild pyrexia of a few days' duration (100–101.4° F.: 37.8–38.55° C.). Full recovery occurred. One patient, put into this category for convenience, was a gynaecological case. The trouble was diagnosed as uterine prolapse with cervicitis and erosion; colporrhaphy was performed, and she developed a mild pyrexia for a few days after operation. A pure growth of Group C streptococci was obtained from the cervix both before and after operation. The wound became clean and the patient recovered rapidly after sulphathiazole medication.

One strain was found on the anaesthetic machine of an operating theatre—a surprising finding, that suggests a possible source of hospital epidemic infection.

Significance of Group C Streptococci

It will be seen from the above series that in the majority of cases infection with these organisms does produce only mild lesions. In the genital tract they can exist as saprophytes, and, in spite of the local trauma of parturition, still cause no infection. With extensive lacerations, however, a mild uterine sepsis can be set up, so that the presence of these streptococci in the pregnant woman should always be noted. In the throat also the tendency is for a mild infection, but there is always a possibility of an acute and anginous inflammation. Infection of the soft tissues can be equally troublesome. In one of our cases it led to amputation of the phalanx of one finger, and in another to osteomyelitis of the zygoma.

It is difficult to assess the significance of the Group C streptococcus in the chronic bronchitis cases. Our 3 cases produced sputa with a mixed flora, but the Group C streptococcus very considerably outnumbered the other organisms. If not actually pathogenic, it would seem to be a great potential danger in view of the one case of bronchitis which led on to pneumonia and septicaemia. Here the patient was indeed gravely ill.

Bacteriology

All the strains gave clear-cut serological reactions with the Lancefield Group C serum, and soluble haemolysin tests were all positive. Biochemical investigation of 46 of our strains was carried out to see if there was any correlation between severity of lesion and type of streptococcus. All were inoculated into trehalose, lactose, sorbitol, and salicin-serum-peptone water, into plain broth, grown on 20% bile-blood, and tested for the presence of fibrinolysin. No correlation could be found between the severity of the lesion and the type of streptococcus causing it.

Sixteen of the 46 strains did not ferment sorbitol but fermented trehalose, thus fitting into Evans's (1944) description of *Str. equisimilis*. Of these 16, 4 did not lyse human fibrin and would therefore appear to be of animal origin. Of these 4, one was from a case of mild tonsillitis, one from a severe anginous throat, one from a chronic osteomyelitis, and the

last from a routine vaginal swab. The other 12 which had human fibrin, and would therefore seem to be of human origin, also came from lesions of varying severity, including a case of severe cellulitis, 3 mild puerperal infections, and 1 abscess. The remainder were from routine swabs, presumably from carriers on whom they were saprophytic.

The large group of organisms (30 in number) which did ferment either sorbitol or trehalose were at first suspected of belonging to the *Str. equi* group. Further investigation, however, showed that they differed in other characteristics. All lysed human fibrin and fermented either salicin or lactose or both. All grew rapidly in plain broth. Eighteen of the strains fermented both lactose and salicin, and included the strain isolated from the septicaemia. But as this group also included many of the mild tonsillitis and carrier strains pathogenicity did not seem to be particularly associated with it. Biochemical typing of the Group C streptococcus did not therefore, appear to us at first to be of much practical value but it was noticed that of 3 strains giving the same biochemical reactions (acid in trehalose and salicin, nil in sorbitol; lactose, positive for fibrinolysin, no growth in 20% bile) 2 were from cervical swabs from mild puerperal pyrexial cases where the organisms were not grown from swabs taken on admission. The other was from the throat of a nurse in the same ward thus suggesting the possible source of the infection.

Conclusion

It is suggested that the appearance of a Lancefield Group haemolytic streptococcus in any lesion should be regarded with some degree of the apprehension which at present is bestowed on the Group A organism, and that, particularly in midwife cases, its presence should be the signal for preventive measures to avoid cross- or auto-infection. Biochemical typing might be of value in tracing outbreaks of minor infection with Group C streptococci in maternity and surgical wards.

CHEMICAL WARFARE EXPERIMENT USING HUMAN SUBJECTS

BY

H. CULLUMINE, M.D., Ch.B., M.Sc.
(*Chemical Defence Experimental Station, Porton*)

Human subjects have been employed for many years to assess the value of certain types of potential chemical warfare agent and the efficacy of suggested defensive measures. All the subjects were volunteers, originally from the staff of the Chemical Defence Experimental Station, Porton, but later from the three armed Services. No one was subjected to a test without first being told the precise nature of the test and the possible consequences to himself. The tests were chiefly routine in nature and hundreds of volunteers have been used in this way. "volunteers from the volunteers" were invited for any test involving risk of injury. The tests for which the subjects were used were roughly of two types—viz., offensive and defensive.

Offensive Tests

The offensive tests included the routine assessments of hundreds of possible lacrimators and sternutators. Volunteers were exposed to these compounds, which were dispersed in low concentration in a gas-chamber, and the times of onset and severity of the typical signs and symptoms of irritation noted. The potency of each compound was determined in this way for comparison with the effects produced by the common standard lacrimators and sternutators. The more promising compounds were further assessed under more realistic conditions. Their trained troops "attacked" over an assault course while they were subjected to heavy concentrations of sternutatory clouds from generators, and their performance was compared with that when under the influence of a cloud of a standard sternutator.

again when no gas cloud impeded them. Simultaneous action of the chemical concentration of the gas clouds ed a more precise assessment to be made. The irritant s from gas weapons were similarly assessed.

the suggestion of Prof. Bartlett, of Cambridge, a constant test based on the rangefinder was used for the quantitative ment of the harassment produced by lacrimators. Harass-concentration curves were produced for the common nators, and an interesting point noted was that for each nator tested there appeared to be a critical concentration e which any further increase in concentration produced, at nost, only a small and militarily insignificant increase in sment. Moreover, it would appear that in each case the al concentration produced an approximately similar sity of harassment—viz., about 50%. (100% harassment ponds to complete blindness for the duration of the test.) intensity of harassment is equivalent to a subject being l for half the time of the test. The subject is, of course, mittently blind, corresponding to the periods of intermittent arospasm which he suffers.

oreover, it was noted that the human eye could become rant," as regards both lacrimation and blepharospasm, to ven lacrimatory atmosphere, no matter what the chemical re of the atmosphere, and whether the concentrations were or low. The time for different subjects to acquire tolerance d enormously—e.g., from 2 to 40 minutes—and this time acquiring tolerance seemed to bear no relation to the oneration or the nature of the lacrimator. This tolerance was iered whether the concentration was slowly falling or slowly g, but a sudden marked increase in the concentration of lacrimatory atmosphere broke down the tolerance. About arter of the subjects showed a definite relapse of tolerance, in about a third of these the relapse was of a "phasic" re—i.e., the lacrimation tended to return and then pass y periodically during the exposure to the lacrimatory osphere.

he effect of harassing agents against armoured fighting icles was also assessed. Trained crews manned the vehicles, ch were then bombarded with projectiles containing harassing nts. A Service medical officer, travelling as "passenger," ssed the effects produced.

he effects of various vesicants on human subjects were also lied. New compounds were compared with the standard icants by placing different weights of the materials under on the skin of volunteers and observing the effects prod-ed. The vesicant power through various types of clothing l equipment and under different atmospheric conditions was ermined. A numerical basis for assessment was introduced that the results could be analysed statistically. This was ed on the finding that the following mean times of exposure (minutes) to mustard-gas vapour saturated at 30° C. are uired to cause the development, in 24 hours, of the various es of burn, under normal English atmospheric conditions.

Description of Burn	Time in Minutes	
	Normal	Hot and Sweaty Skin
1) red	1	0.5
2) and swollen	2	1
3) and swollen, with	3.5	2
4) pinhead blisters	4	—
5) small central blister	4	—
6)	6	3.5

One interesting investigation was the comparison of the sensi-ity of the skin of various regions of the body to vesicant mage. The following increasing order of sensitivity was dis-vered: palms of hands and soles of feet, palmar surface of ingers and back of hand and fingers, lateral surface of fingers d skin of the body generally, skin of the genitalia.

The burning power of vesicant vapours, both in the gas-amber and in the field, was studied and the dosage of vapour make a soldier a casualty determined by direct experiment. his was done under varying atmospheric conditions, too, by e use of a gas-chamber in which the relative humidity and e temperature could be controlled. It had long been known at hot and sweaty skin was more sensitive to vesicant vapour an was cool and dry skin, and by these experiments a more

precise correlation between vapour dosage for casualty produc-tion and atmospheric variables was obtained. The factors involved in producing the increased sensitivity of hot and sweaty skins were also studied. Our experiments seemed to indicate that the amount of moisture on the surface of the skin was the main determining factor, the following order of increasing sensi-tivity to vesicant vapour being found: cold dry skin, hot dry

FIG. 1.—Experimental mustard-gas vapour burns of the scrotum.

FIG. 2.—Burns caused by mustard-gas spray through clothing (24 hours after contamination).

skin, cold moist skin, normal (temperature) dry skin, normal moist skin, hot moist skin. This also probably accounts for the fact that under normal British climatic conditions the nor-mally moist regions of skin—e.g., genitalia, axillae—react more severely to vesicant vapour than the rest of the skin surface (see Fig. 1).

The penetrative and burning powers of liquid vesicant drops through various types and conditions of clothing were also investigated. Different sizes of drops were used, and they were dropped from a height on to the clothed subject and at a terminal velocity corresponding to that of spray. From the results of these experiments calculations were made to estimate the degree of vesicant contamination required to make a soldier a casualty. The validity of these calculations was checked by direct exposure of soldier volunteers to vesicant spray in the field (see Fig. 2).

A somewhat similar problem was presented by the request to determine the burning power of phosphorus through various types of clothing. Here known quantities of burning phosphorus were dropped from a height on to clothed volunteers. (The phosphorus was supported on a 1-amp. fuse wire which, on passage of an electric current, ignited the phosphorus and allowed it to fall.) Calculations similar to the vesicant calculations were then made. The relation between vesicant-vapour dosage and reversible eye-damage was also determined, chiefly by means of a constant-flow method through an eye-mask.

Defensive Tests

The above offensive tests were a necessary preliminary to experiments designed to evaluate protective measures and equipment; the possible hazards had first to be determined before methods of defence could be formulated. Thus the methods used in assessing the value of protective devices were very similar to those already described. For example, vesicant injuries to the eye were produced and treated with various therapies. Decontaminating ointments, creams, powders, and solutions were tested on the contaminated skin of volunteers. Protective clothing and impregnated clothing were assessed on subjects exposed to vesicant vapour dispersed in the gas-chamber or in the field and in concentrations known to be normally damaging. The hazards presented by traversing or occupying contaminated ground, and methods of reducing them, were also determined, while the effect on military efficiency of wearing various types of respirators was measured by the use of fully trained soldier personnel.

Of course the experience gained by these large-scale experiments on human subjects was often utilized for non-chemical-warfare problems. Thus, to quote a few examples, the problem of facepiece and rubber dermatitis, the question of irritability of garments heavily impregnated with D.D.T., and an attempt to determine the factors involved in the production of khaki or textile dermatitis were typical commitments.

I wish to thank the Chief Scientific Officer, Ministry of Supply, for permission to publish this paper. I must also pay tribute to Surg. Capt. A. Fairley, R.N.(ret.), for long a lone pioneer in this work on human volunteers; to Lieut.-Col. S. Curwen, R.A.M.C.; and to many other colleagues at Porton whose work I have freely quoted. Finally, my sincerest thanks to, and admiration for, the host of volunteers who made all this work possible.

Medical Memoranda

Removal of Large Ovarian Tumour Complicated by Cardiac Failure

The interest in the following case lies in the size of the tumour removed and the remarkably rapid recovery of a failing heart as soon as the pressure thereon was eased.

CASE REPORT

Early in 1946 an African village woman, aged about 50 and of average stature, was admitted to hospital at Winneba. She stated that she had suffered increasing abdominal girth for three years. She was found to be very thin, dyspnoeic, and slightly cyanotic. The cervical veins were full. Cardiac dullness was increased to the right. Cardiac rhythm was regular, rate 90 a minute at rest. The interval between the first and second apical sounds was increased. Both lower limbs were oedematous. The abdomen was grossly distended. Abdominal and pelvic examination revealed the presence of a smooth, firm tumour which appeared to fill the pelvis and abdominal cavity completely. Its upper limit could not be defined. The uterus and rectum were prolapsed. After a week's rest in bed her general condition improved slightly, and operation was decided upon.

Under open anaesthesia (3:2 ether-chloroform mixture) laparotomy was performed through a long right paramedian incision, revealing a smooth, white, glistening tumour, areas of which fluctuant, extending well down into the pelvis, where its pedicle was felt on the right side. Laterally the tumour spread out over the flanks, and above was pressing on the liver. Fortune gut was not adherent to it. With considerable difficulty, on its size, the tumour was withdrawn from within the peritoneal cavity, the pedicle was clamped, the mass removed in one piece, abdomen closed. Camphor in oil had been given intramuscularly an hour before operation and nikethamide during the operation the pulse became feeble and irregular.

Examination of the tumour showed it to be a typical mucinous cystadenoma of the ovary. The proportion cyst to solid was approximately two to three. The tumour weighed (18.6 kg.). After operation the patient made a rapid and uneventful recovery. She left hospital one month later in good health.

I am indebted to the Director of Medical Services, Gold Coast, for permission to publish this report.

Colonial Medical Service, Gold Coast.

Medical Officer

Helminths Infective to Man in the Syrian Hamster

The Syrian hamster (*Cricetus auratus*), which is susceptible to several human diseases (e.g., leishmaniasis, tuberculosis, etc.), is being increasingly used, both in this country and in America, as a laboratory animal. In a recent Stunkard (1945) recorded the finding of the eggs of the tapeworm, *Hymenolepis nana*, in the faeces of a batch of animals purchased for experimental purposes. Since this species is directly infective to man, requiring no intermediate host, the author stressed the risk of infection being acquired by laboratory workers, animal-house attendants, and others handling the animals. *H. nana* commonly occurs in rats and mice, and several workers (Saeki, 1920; Uchimura, 1922; Kiribayashi, 1933) have succeeded in infecting man with eggs from these sources; hence there is ground for the belief expressed by Chandler (1922) and Faust (1939) that human infection may be acquired from eggs derived from rodents. Once acquired, human infection with *H. nana* may later reach serious proportions by reason of internal auto-infection (Hunninen, 1939).

In recent months a number of hamsters which had been used for experimental infections of kala-azar in these laboratories have been examined post mortem for helminth parasites. Out of a total of 160 animals, 19 (11.9%) were found to harbor *H. nana*, some being fairly heavily infected. One specimen yielded no fewer than 22 adult worms. Since most of the infected individuals belonged to one batch there is a possibility of a much higher incidence in other cases. Further, 83 animals (51.9%) were infected, some very heavily, with the oxyurine nematode *Syphacia obvelata*. This species is also believed to be infective to man, a case of human infection having been reported from an American child in the Philippines (Riley, 1919). Several more recent cases of *S. obvelata* infection have, however, proved to be spurious (Craig and Faust, 1945).

In view of the possibility of human infection with these worms having been acquired by contamination from the faeces of these infected hamsters, it was deemed advisable to make a examination of all personnel involved in handling the animals. Accordingly, two stool samples and seven N.I.H. swabs* at daily intervals were taken from the four individuals in question and examined respectively for the eggs of *H. nana* and *S. obvelata*. All were negative.

Hence, despite the fact that human infection with these helminth species does undoubtedly occur, and in view of the fact that no special precautions were taken in handling the hamsters, the risk of infection to laboratory workers and animal-house attendants does not, in practice, appear to be a serious one.

Reviews

X-RAY THERAPY FOR ACCESSIBLE CANCER

The X-Ray Treatment of Accessible Cancer. By D. Waldron Smithers, M.D., D.M.R. (Pp. 147; illustrated. 40s.) London: Edward Arnold and Co.

This is a monograph describing the experience at the Royal Cancer Hospital, London, in the treatment of cancer, chiefly of the skin. It is profusely illustrated with photographs of apparatus and of patients, and with isodose curves applying specially to the use of contact x-ray therapy in the treatment of skin cancer. The clinical photographs include some striking examples, in colour and in black and white, showing both radiation reactions and clinical results in skin cancer and cancer of the lip. The text is clearly written and the author brings out the essential points of the principles influencing the choice of technique and of apparatus. A chapter is devoted to classification and staging of cancer with a full account of records, including a punch card system for abstracting information from the records, making use of punching, and sorting by hand.

In a clear but somewhat technical account of the mode of action of radiation on malignant cells, the author correlates conclusions reached by several workers in cytological fields and stresses the need for studying the response to radiation of individual tumours. Examples are given of attempts to do this by means of differential cell counts, and a number of such counts, graphically represented, is given. While with most of these the clinical result corresponds with the indications of the cell count, one (Fig. 39) shows an unfavourable cell count, but a good clinical result, 2½ years after treatment. This result calls into question the whole method. The techniques used are clearly described, and full use has obviously been made of isodose data provided by the physicist, together with ingenious devices to ensure accuracy and ease of treatment with protection of structures, such as the eye and mucous membranes, which should not be treated. A test of statistical significance of results is used to show that a fractionated is better than a single-dose method of treatment, but the author is in error in comparing his own figures for fractionated treatment with those of another clinic for a single-dose method.

The book is attractively produced, and interesting to read. The author and publishers are to be congratulated on the project and its fulfilment.

BIOLOGY OF CELLS IN TISSUE CULTURE

Biology of Tissue Cells. Essays. By Albert Fischer, head of the Biological Institute, Carlsberg Foundation, Copenhagen. (Pp. 348; illustrated. 31s. 6d.) Copenhagen: Gyldendalske Boghandel Nordisk Forlag; London: Cambridge University Press, 1946.

Though not indicated in the title, this book actually deals with the biology of cells in tissue culture. It is not a monograph or textbook of tissue culture, but a series of essays based on the author's own experimental data, and on those of other workers, and it considers the subject from the standpoint of the biology of tissue culture cells and their relation to the life of the tissue cells in the whole organism.

The results of tissue culture studies have proved to be a disappointment to histologists of the old school, because in culture the morphological characters of the cells are lost by dedifferentiation, so that finally only three types of cell are morphologically recognizable—viz., reticular tissue cells (fibroblasts), mosaic tissue cells (epithelium), and wandering cells. Thus, chondrioblasts, osteoblasts, muscle fibres, and cardiac muscle cells become morphologically identical as "fibroblasts." But although morphologically indistinguishable, the cells retain certain potentialities characteristic of the embryonic stage from which the explant originates. Thus, the tissue culture provides interesting material for the study of characters, other than morphological, by which the cells differ from one another. In the last analysis no doubt these differences depend on chemical differences, as is already admitted to be the case with morphologically indistinguishable cells from different species of animals.

The author advances evidence in support of the view that the tissue culture represents, not a cell colony in the real sense

of the term, but an organism-like system, or tissue-cutting, presenting signs of organization, of polarity, of regeneration when injured, and of mutual dependence of the cells on one another, involving some elementary division of function. Why it grows only to a certain size, what stimulates its growth and its polarity, and what factors inhibit growth are subjects to which the author has given much thought.

The book is interesting and stimulating, and, on the whole, written in excellent English, on which the translator is to be congratulated. All the same, the language could have been improved by an English editor: the punctuation is at times odd, and the use of such words as "loose" for "lose," "long-time" for "prolonged," "blood coal" for "blood charcoal," etc., give an awkward tang to the reading. This is perhaps captious criticism of a laudable effort: one would be happy to be able to write a foreign language oneself half so well. The print and get-up are excellent.

BILIARY AND ALIMENTARY ANASTOMOSIS

Operative Anastomoses Between Biliary and Gastro-Intestinal Tracts. A Review of Earlier Literature and a Clinical Study of 809 Swedish Cases. By Gunnar Redell. (Pp. 371; illustrated. No price given.) Uppsala: Almqvist and Wiksells Boktryckeri-A.B.

To collect and analyse the details of some 800 cases of any surgical condition is a herculean task, but it has been successfully undertaken by Dr. Gunnar Redell of Uppsala, whose *Operative Anastomoses Between Biliary and Gastro-Intestinal Tracts* first published in Sweden in 1940 has now been translated into English. The main part of the book consists of summarized histories of 809 cases of such anastomoses culled from all the Swedish hospitals in the period 1914-38, but in the first 180 pages the author gives an excellent review of the previous literature and discusses all important aspects of the subject, experimental, pathological, and operative. Fourteen separate indications for these operations are detailed, including cancer of the pancreas, stricture of the bile ducts, accidental and post-operative lesions (which in view of the findings of the previous records we were surprised to see accounted for but 44 of the 809 cases), dyskinesia, stones, and congenital conditions.

We think that the surgeon will not find anywhere a more complete or balanced analysis of the very considerable literature which in the author's bibliography extends to 1,100 articles and papers. We note with commendation that this list is world wide in its embrace and not limited, as is too often the case in monographs, to the literature of one or two countries. For this reason it was all the more surprising to find no reference to E. Horgan's volume on *Reconstruction of the Biliary Tract*, which is the only other extensive monograph we have come across covering much the same territory. However, this small omission in no way detracts from the great value of Dr. Redell's book, which will for long remain the most informative guide to a rather involved subject. That it needed attention is obvious from the high overall mortality which the author quotes from the literature and which his own statistics corroborate, only 146 of his series, many of which of course were cases of irremovable neoplasm, being alive at the time of the investigation. In 89 of these barium meal examinations were done, and at the end of the book a series of half-tone radiographs and of line reproductions, showing the degree to which the contrast medium entered the biliary system via the anastomosis, greatly enhance its practical value.

The book is one we can unhesitatingly recommend to the surgeon who is particularly interested in this important branch of his subject and can procure a copy from Uppsala.

DYNAMIC PSYCHIATRY

Principles of Dynamic Psychiatry. Including an Integrative Approach to Abnormal and Clinical Psychology. By Jules H. Masserman, M.D. (Pp. 322; illustrated. 20s.) London: J. B. Lippincott Company.

In this book the author has tried to integrate various biological and psychological disciplines into a biodynamic theory of behaviour and to check the principles of this theory against animal experiment, clinical observations, and the rationale of various forms of therapy in the behaviour disorders of man. The first part is concerned with definitions of the scope of psychiatry followed by a description of psychological and psychopathological concepts. The psychoanalytic approach is discussed and the psychoneurotic and psychotic reactions are

described. In the second part all this is correlated with experimental work on animals and various criticisms are dealt with. Appendices comprise a full case history of a psychoneurotic with psychosomatic symptoms, the psychoanalytic formulations of the psychoses, a list of films suitable for teaching purposes, and a note on principles of group communications used in propaganda. There is a full bibliography and a glossary of psychiatric terms to complete the book.

As a work of reference this volume is of undoubted value, but it is written in a style which makes consecutive reading difficult, and the use of many technical terms unfamiliar to the general reader makes the glossary essential. Nevertheless the approach to psychiatric problems is a rational one and represents the general trend of modern psychiatry. We shall look forward with interest to the forthcoming volume on the practical application of the theories formulated in the present work.

AN AUSTRALIAN SURGEON'S MEMOIRS

In My Fashion. By Herbert M. Moran. (Pp. 310. 15s.) London: Peter Davies, 1946.

For the friend becoming increasingly restive during a long convalescence, for the retired doctor who finds that the world has been steadily going from bad to worse since the days of his youth, and for anyone who enjoys wit, zest, pugnacity, lost causes, and tilting at windmills this work would be an excellent gift. The author, an Australian surgeon, died of a malignant melanoma just before the book was published, and his account of his disease in the last chapter is a moving example of that form of literary expression at which the British have always excelled: eloquent acceptance of death.

However, Mr. Moran was pre-eminently a skilful raconteur, and most of the book is composed of anecdotes about psychopaths, malingerers, homosexuals, eccentrics, and bemused illiterates that he encountered while serving in the R.A.M.C. during the recent war—the "poor types," as they were called—the "submerged tenth" of our population. The treatment accorded to these men by the Service authorities, and in particular by the psychiatrists, roused the author to criticisms that are always scathing, often unfair, but certainly entertaining; and his observations on the effects of the "dole," medical certification, and incoordination between the medical Services will find an echo in the hearts of many doctors even if their minds consider his judgments rash and biased.

A sympathy with the Italian people (he knew the English colony in Italy well) and with Mussolini, whom he met on several occasions, caused the author to condone the Abyssinian venture to the extent of volunteering to serve with the Italian army in Africa. His adventures there are vividly described, but his sympathetic attitude to the campaign must be repugnant to most Englishmen to-day.

Notes on Books

Bulletin No. 6 of the Industrial Welfare Division of the Australian Department of Labour and National Service deals with *Atmospheric Conditions in Australian Textile Mills*. It describes the temperature, humidity, and air movement experienced in half the textile mills of Australia, which employ four-fifths of the workers in the industry. The observations are presented in the form of charts which show the range of dry-bulb temperature and humidity found to be (a) comfortable for the operative, (b) uncomfortable for them, and (c) harmful, within the endurance limit indicated. Other sections of the Bulletin discuss the frequency of difficult outside atmospheric conditions, the control of radiant heat, and the maintenance of clean air. The Bulletin should prove a useful guide to factory managers, especially those engaged in worsted and cotton spinning. Booklet No. 3 reports on *Industrial Accident Records, their Compilation and Use*. The booklet describes the system used in a number of Australian factories during the past two years, and follows the standard methods recommended in this country by the Royal Society for the Prevention of Accidents. It also embodies schemes which aid the collection and tabulation of accident data, and relate the occurrence of accidents to definite causes. Both publications may be had from the Department of Labour and National Service, Nicholas Building, 37, Swanston Street, Melbourne.

Self. A Study in Ethics and Endocrinology, by MICHAEL DILLON (William Heinemann Medical Books; 6s.), is a plea for the understanding of self, not only of oneself but of other selves, for only thus can there be any advance in charity, in civilization, and in a true ethic. In the compass of 122 pages the treatment of this

subject cannot be anything but superficial, but it is at least provocative of thought. The first part deals with the influence of body, especially of the endocrine system, and this is illustrated by discussion of the vexed subjects of homosexuality and hermaphroditism and the biased and prejudiced attitude of the public to these problems. In the second part the question of the correlates of these bodily processes is dealt with in chapters on personality, the masculine and feminine type of mind, and free will. None of these problems does the author solve, nor does he pretend to, but he approaches them with an open mind and not, as so many professional endocrinologists, psychologists, and other-ologists, exclusively from the standpoint of their own specialties. The chief object of this readable and pleasantly written little book will be to stimulate thought and (we hope) further reading.

The United States are justifiably proud of the memory of William Beaumont. As Dr. John Fulton points out, his physiological observations on Alexis Saint Martin were of the greatest significance. The basis of one well-studied case Beaumont was able to chart the course of medical thought in the sphere of the physiology of digestion. We turned, therefore, with pleasant anticipation to a book with the engaging title *William Beaumont's Formative Years* (New York: Henry Schuman; \$6.00), but we must admit to being rather disappointed. The book merely comprises two Beaumont's early notebooks, 1811 to 1821, with annotations and an introductory essay by Genevieve Miller. These diaries record everything that interested him greatly, whether what he observed himself or what interested him in the writings of others. It is an unclassified collection of his thoughts and might provide the material from which his formative years could be clearly grasped. The book handsomely produced with a number of pleasant contemporary illustrations.

We welcome a second edition of Dr. OTTO SAPHIR's *Auto Diagnosis and Technique* (New York, Paul B. Hoeber, 55). The book remains of reasonable size in spite of revision and enlargement and contains a vast amount of useful information expressed in clear and attractive language. The gross changes in diseases of the biliary system, vitamin deficiencies, and tropical diseases are now included, and investigation of accidental death has been more thoroughly dealt with. The opening chapter, concerning the legal aspects of obtaining permission to perform the necropsy, is of considerable interest. Most of the book is occupied by short pithy descriptions of morbid processes. As the author explains, this part is not designed to replace a textbook of pathology but to serve as a working guide to aid in recognition of demonstrable anatomic lesions. The book will certainly be of assistance to those whose experience of carrying out routine post-mortem examinations is limited.

Dr. WILLIAM BROWN's book entitled *Personality and Religion* (University of London Press; 9s. 6d.) is, in the main, a revised and abbreviated edition of *Mind and Personality*, in which he has incorporated chapters from another of his books, *Science and Personality*, all of which have been out of print for some years. We note that he now lays very little stress on abreaction, of which, in the past, he was the leading exponent. In its present form the book embodies the results of twenty years' further experience in deep mental analysis of psychoneurotic patients as well as of more normal personalities. He also elaborates his helpful conception of the contrast between individuality and personality, which is perhaps the most interesting feature of the book.

It must be said at once that *A Pocket Obstetrics*, by ARTHUR C. BELL (J. and A. Churchill; 7s. 6d.) is an excellent little book. "An attempt to present the fundamental lines of approach to the practice of obstetrics both normal and abnormal" has succeeded. When in conjunction with her practical work the pupil midwife will find all that she requires here. The busy general practitioner and his wife could use this book for rapid reference with benefit, and a harassed medical student during revision will be grateful for the logical presentation of a subject never easy to master. The publishers are to be complimented on the high standard of the production. The attached bookmark may be copied with advantage by themselves and to the reader by many other publishers.

Pending a complete revision of the *Ship Captain's Medical Guide* a new edition has been printed for the Ministry of Transport. The 18th edition, besides new material, contains information which has been issued in the form of Notices to Masters. The medical sections have now been omitted and are published separately. Copies of the *Ship Captain's Medical Guide* (price 3s. 6d.), of the medical sections, and of amendments to each of these publications may be obtained directly from H. M. Stationery Office, or through any bookseller.

The Royal Life Saving Society has published a twenty-first edition of its illustrated *Handbook of Instruction* which sets out the method approved by the Society for release and rescue of the drowning, for resuscitation of the apparently drowned. It is published at 14, Devonshire Street, London, W.1.

LONDON

SATURDAY · OCTOBER 19 1946

THE FUTURE OF PENICILLIN

We are glad to announce the publication of a full-scale work on penicillin by British writers.¹ Edited by Sir Alexander Fleming, who is himself the author of two chapters, it includes contributions by 27 other workers and covers the whole field of its subject, from chemistry, manufacture, pharmacy, and pharmacology to every form of clinical application. There is necessarily some variety of style and method among so many writers, and even difference of opinion among them on minor points, but such lack of uniformity is more than counterbalanced by the advantage of having contributions from those who have special experience in particular fields. The scope of penicillin treatment is so wide that no one can have had practical experience of all aspects of it: it includes, for example, such specialized spheres as ophthalmology, major chest surgery, venereal disease, and plastic surgery. The obstetrician, the dermatologist, the orthopaedic surgeon, and others have also had the opportunity of discovering what penicillin can do in facilitating their work, and the fruit of all their experience will be found here.

A study of this book will provide almost any reader with new ideas for ways of using penicillin, and, unless the constantly reiterated injunction to determine whether or no the infection is caused by a penicillin-sensitive organism is well observed, it may safely be predicted that a good deal is going to be wasted. Bacteriological investigation, though always advisable unless the clinical diagnosis decides the nature of the infection, would seem to be particularly necessary in peritonitis and other acute abdominal conditions, in which the usefulness of penicillin has yet to be fully determined, and in infections of wounds, of the air passages, and of the urinary tract. Several important applications will probably be new to many readers. One is the treatment of sepsis neonatorum, a term here used to describe many of the possible effects of the "neonate's" first contact with the microbic world, and including umbilical infection, nasopharyngitis and pneumonia, skin infections, and various other forms of sepsis. Of 69 such cases treated at Great Ormond Street 60 could be investigated bacteriologically, and in precisely two-thirds of them the infection was staphylococcal; there is thus more than an even chance in such a case that the organism concerned will be penicillin-sensitive. Since infants need very small doses compared with the adult, there need be no hesitation in giving any doubtful case the benefit of penicillin; indeed, this appears to be a branch of treatment in which the extravagant method of oral administration might well be

exploited fully. Another and much wider application is to "cover" an operation which normally carries a serious risk of sepsis; examples of this vary from dental extraction in rheumatic subjects to Caesarean section in an advanced stage of labour. Penicillin inhalation still requires further study, but it has been shown to be a possible alternative to injection for producing a systemic effect, and has been found to give good results in certain infections of the air passages and lungs, particularly in some cases of acute bronchitis. In this connexion it is interesting that the Swiss authors P. Geiser, K. Schaub, and H. Stauh² have recently claimed good results by this method even in the treatment of pneumonia.

With this up-to-date review of the present achievements of penicillin treatment before us it is tempting to speculate on future lines of development. An unknown factor on which these must largely depend is the supply position. It is true that supplies are understood to be adequate for normal and legitimate use in this country, but no one can foretell what the consumption may be in the first wave of popular demand. Moreover, many other countries still have little or none, and we should presumably export any surplus over normal requirements in the interests both of humanity and of the national exchequer. But to anticipate a day when supplies will really be unlimited and perhaps cheap—what can we do which is not being done now? Quite the most extraordinary property of penicillin is that it is for all practical purposes non-toxic; enormous doses can be given without fear of ill effect if there is anything to be gained by doing so. Perhaps the only contraindication to a large dose is in the treatment of gonorrhoea, when it may unduly mask the subsequent signs of coincident syphilis. There is little doubt that larger doses will be given for the treatment of most conditions, if only in order to prolong the interval between injections. Possibly administration by the mouth, which calls for about five times the intramuscular dose, will come into favour, at least for less serious conditions. Finland³ and others⁴ in America have already shown that this is a perfectly feasible method of treating gonorrhoea and even pneumonia. We shall also doubtless see an enormous extension of prophylactic use, embracing wound treatment, surgical operations of all sorts, obstetrics, and even some of the risks of social intercourse. Animals must not be forgotten: there is a chapter on veterinary use in this book, and the scale of dosage required in a cow is considerable.

Perhaps more important than any of these things is the possibility of extending the scope of penicillin treatment to infection by less sensitive bacteria. It is unfortunate that simplicity of statement should hitherto have demanded the categorization of bacteria into sensitive and resistant species. There is no such clear distinction among many of them, but every gradation from sensitivity to as little as 0.01 unit per ml. to resistance to several hundred units. *H. influenzae* is classed as insensitive in one chapter here, and recognized as reasonably sensitive in another; it is actually quite sensitive enough, as was pointed out originally by P. Forgacs, R. Irene Hutchinson, and R. E. Rewell⁵ and by

² *Schweiz. med. Wschr.*, 1946, 76, 285.³ *J. Amer. med. Ass.*, 1945, 129, 315.⁴ *Ibid.*, 1945, 129, 320.⁵ *Lancet*, 1945, 1, 785.¹ *Penicillin, its Practical Application*, 1946, Butterworth and Co., 30s.

M. Gordon and K. Zinnemann⁶ in this Journal to justify good hopes of benefit from intrathecal injection in *H. influenzae* meningitis. These observations have been confirmed by W. L. Hewitt and Margaret Pittman,⁷ who add the interesting observation that penicillin X is more active against this organism than penicillin G, although streptomycin is rather better than either, both *in vitro* and experimentally *in vivo*. *Proteus* is condemned as insensitive in two clinical chapters of this book; it is in fact usually inhibited by about 8 units per ml., a concentration which is readily far exceeded in the urinary tract, if nowhere else. Almost all authors have agreed in disregarding typhoid bacilli and other *Salmonellas* as hopelessly resistant, in spite of Florey's prophecy made five years ago that with more and better penicillin we should come to the stage of attacking these infections. That prophecy is now fulfilled. Bigger having shown that penicillin and sulphathiazole exert a synergic action on *Salmonella typhi*, C. J. McSweeney⁸ has treated six cases of typhoid fever with full doses of sulphathiazole and large doses of penicillin—2,500,000 units daily—with apparently remarkable results.

These things were better left unsaid if they encourage indiscriminate use. Such adventures as the exploration of new fields of treatment are only for hospitals where the most thorough clinical and laboratory control can be carried out. In private practice disappointment can be avoided only by adhering to accepted lines of treatment, and these may at last be learned from a comprehensive home-produced publication.

EVOLUTION OF JOURNALS ON GENETICS

There are a few men of science of whom it can be said that their work and influence left a branch of knowledge so radically altered that it is difficult to conceive what the course of development would have been without them. Among this company must be included Karl Pearson. If to-day there are flourishing schools of statistics, if what would have seemed but a few years ago to be refined applications are now almost commonplace in hygiene, in medicine generally, and, in fact, in almost every division of experimental science, then we must recognize that it is to Karl Pearson above all that our thanks are due. Those distinguished men who have so ably built upon the foundation he laid would be the first to acknowledge their debt.

The more tangible of the things that Pearson has handed on to another generation, apart from a vast collection of published works, are the Galton Chair of National Eugenics, at University College, of which he was the first incumbent, the Francis Galton Laboratory for National Eugenics, and three journals of which he was the founder—*Biometrika*, the *Annals of Eugenics*, and the *Treasury of Human Inheritance*. *Biometrika* was founded in conjunction with Francis Galton and W. F. R. Weldon in 1901 and continued to be edited by Pearson till his death in 1936, since when the editor has been his son, Prof. Egon Pearson. *Biometrika*, an essential requirement and handbook for every statistician and biometrician, has included much else of outstanding value and, indeed, stamped as it is with the vigorous personality of its founder, much

to interest and entertain the more general reader. There are not many scientific journals that would publish an article extending to a hundred pages, together with more than a hundred pages of plates, on the skull of Oliver Cromwell. Nor would the name *Biometrika* lead the reader to expect the occasional re-writing of history (and who shall say wrongly), just because the editor-author enjoyed doing it. Even he, however, appears to have shrunk from saying of George Buchanan to an audience at the University of Edinburgh: "Chief among these venturers, and perhaps, owing to his great literary gifts, the basest hireling scholar of all the ages, stands George Buchanan," for we find this remark not in the published lecture on Buchanan's skull but in another paper, not read to a Scottish audience.

The *Annals of Eugenics* has a shorter history. The first number appeared in 1925, and five volumes had been completed when, in 1934, the editorship passed, with the Galton Chair, to Prof. R. A. Fisher. In founding the *Annals* Pearson felt that "the time seems fully ripe for the issue of a journal which shall devote its pages wholly to the scientific treatment of racial problems in man." From the beginning papers were included which dealt with human genetics, but the chief emphasis was laid on the national group as the most important unit, a sentiment enshrined in the "National" which precedes the word "Eugenics" in the titles both of the Chair and the Laboratory. While maintaining the high tradition of the *Annals* Prof. Fisher laid more emphasis on the individual aspects of the subject, together with the background of mathematical statistics needed for the solving of genetic and related problems. The change in the subtitle from "A Journal for the Scientific Study of Racial Problems" to "A Journal Devoted to the Genetic Study of Human Populations" sufficiently expresses this alteration. As might have been expected of one of the leading scientific men of our own day, the seven volumes issued under Prof. Fisher's editorship represent a remarkable achievement, and every serious student of human genetics, and of some other subjects too, needs them for constant reference.

Last year the Chair and the editorship of the *Annals* passed to Prof. L. S. Penrose. Prof. Penrose, with his background of mathematics, psychology, and medicine, has made notable contributions in the field of human genetics, psychiatry, and mental deficiency. For a number of years before the war he was Research Medical Officer at the Royal Eastern Counties Institution at Colchester. From 1939 until his recent appointment to the Galton Chair he held a research post in Canada. Among his notable publications may be mentioned a very fine and thorough survey of 1,280 cases of mental deficiency. This monograph, prepared with characteristic care, will remain a valuable storehouse of information for years to come. His work on maternal age in relation to mongolism and his studies on phenylpyruvic amentia may also be singled out as examples from a long list. The first medical holder of the Chair has naturally made some further alteration in the policy of the *Annals*, which will in future be more specifically concerned with medical genetics, and the sub-title now becomes: "A Journal of Human Genetics." Two numbers have appeared under Prof. Penrose's editorship and it is clear that the *Annals*, while maintaining its high standard and without excluding a proportion of highly technical papers, will in future have a more direct appeal to the

⁶ *British Medical Journal*, 1945, 2, 795.

⁷ *Publ. Hlth. Rep., Wash.*, 1946, 61, 763.

⁸ *Lancet*, 1946, 2, 114.

medical man and a most powerful appeal to those medical men with a special interest in genetics.

The third publication, the *Treasury of Human Inheritance*, conceived on the same generous scale as the others, a unique source of genetic data. For some years the sole writer (with collaborators) has been Dr. Julia Bell, whose admirable monographs have been universally praised. It is to be hoped that she will continue to produce them. We are told that in addition the *Treasury* will now be used for the publication of data too extensive for the *Annals* or not in themselves of immediate medical significance. In this way a fine body of material will be built up for future reference.

The Galton Chair has a twin, the Weldon Chair of Biometry, the first and present holder of which is Prof. B. S. Haldane. Amongst his many distinguished activities Prof. Haldane has made contributions of the greatest importance to human genetics. He and Prof. Penrose are certain to do much for the subject in the future, while the *Annals* will be unique as a medium of publication in this field.

HENS' EGGS AND SALMONELLA INFECTIONS

In a previous annotation¹ we discussed eggs as reservoirs of salmonella infections and pointed out that ducks' eggs were definitely implicated as a cause of food poisoning in man, but that the egg of the hen had a much cleaner record. Although this is still true, evidence is slowly accumulating that strains of salmonella of food-poisoning type may be associated with hens' eggs. The increased use of dried eggs in this country makes the subject of great practical importance. A recent paper by F. E. Chase and M. L. Wright² gives particulars of the examination of 2,400 hens' eggs for salmonella strains. Of these eggs 1,000 were laid by fowls which reacted to the *S. pullorum* strain and were therefore from infected flocks; *S. pullorum* was isolated from 61 eggs (6.1%). This strain, however, is harmless to man. No salmonella organisms were obtained from the exterior of 400 eggs in this group. The other 1,000 eggs were from healthy flocks, and no salmonellas were isolated. On the other hand, examinations of dried egg powder made from hens' eggs have been less reassuring. For example, N. E. Gibbons and R. L. Moore,³ examining Canadian egg powder, found salmonella strains in 28 samples (7.4%), and 11 but 5 (*S. pullorum*) were potentially pathogenic to man. There have been outbreaks of food poisoning in man, associated with the use of dried egg powder, during the war in this country.

While outbreaks of food poisoning implicating hens' eggs are excessively rare, J. Watt⁴ described an outbreak of twenty-eight cases of food poisoning on board a merchant vessel due to *S. montevideo* in hens' eggs eaten in a salad. The strain was isolated from several of the unused shell-eggs. M. Crowe⁵ in this country has described a small outbreak of food poisoning very probably caused by a hen's egg. The case against the duck is not only that pathogenic salmonella strains are found but that ducks are liable to infection with these strains, and the organisms are then present in the egg yolk. Certain varieties of duck seem to be especially liable to this infection. So far this chain of evidence seems to be lacking for the hen. The nearest approach to it is contained in an important paper by R. F. Gordon and A. Buxton⁶ dealing with the isolation

of *S. thompson* from outbreaks of disease in chicks. This strain is a fairly frequent cause of food poisoning in man. The authors isolated it during 1943 and 1944, on forty-four occasions from thirty-one outbreaks in chicks and two in ducklings. This organism was isolated from the intestinal tract of two adult fowls but not apparently from the interior of any eggs.

Many more investigations are necessary before any final opinion can be given, but the present position seems to indicate that fowls can harbour salmonella strains which are potentially pathogenic to man. There is no evidence, however, that specific infections with these strains can infect the egg yolk, as in ducks' eggs. Their presence in hen excreta explains how in dried egg mixtures it is possible to find pathogenic salmonella strains. The method of preparation of dried egg powder, if inadequately supervised, may facilitate infection. The health hazard from individual hens' eggs seems to be negligible, while that from dried egg powder is much more considerable. Investigations have shown that the drying during manufacture reduces the risk very much but does not eliminate it entirely, and there is always the possibility of infection after drying. A high standard of cleanliness and care in the factory is necessary, as are measures to exclude unsound eggs. A good deal is being done in this direction.

A COURSE IN CHILD WELFARE

Arguing that there is need for organized training for those holding responsible posts in connexion with the welfare of children of all ages up to 16, the National Council for Maternity and Child Welfare has now issued the second report of its group committee on the whole subject of "Training in Child Welfare."¹ It recommends what is, in effect, an advanced course of training in the care of healthy children for those "who do not want to nurse sick children and do not want to become teachers." The course recommended would, it is hoped, qualify students for higher posts in children's homes and nurseries or as inspectors and supervisors of such establishments, and also produce a supply of "fully qualified teachers and tutors in the welfare of children of all ages." Lest it might be thought that the main object is to create what the report at one stage terms a "new profession of child welfare," it should be stated that what is really essentially contemplated appears to be the training of teachers—a sort of "staff college" in child care and treatment—who can help in the broader and more important task of preparing and helping parents in the job of bringing up their children. Such preparation, it is argued in an introduction, can take place in three stages. The first should form part of general education in schools, and Part II of the present report deals in some detail with the question of instruction in child care in secondary schools and county colleges. The second stage of preparation appears to lie in such colleges and in youth organizations, and the third stage is summed up as making facilities for parentcraft freely available for adults in addition to the advice given to mothers in welfare centres and by health visitors. All this will require more teachers, and it is argued that to secure well-qualified persons it must be done by producing a new group—not by transfer from existing professions (teachers or nurses) with supplementary courses. It proposes that such teachers shall be trained in recognized colleges with a three-years course, and that "child welfare workers"—those wishing to take senior posts in nurseries or children's homes—shall go to the same colleges for a two-years course. It is further proposed

¹ *British Medical Journal* 1944, 2, 760.

² *Canad. J. Res.*, F., 1946, 24, 77.

³ *Ibid.*, F., 1944, 22, 48.

⁴ *Publ. Hlth. Rep., Wash.*, 1945, 60, 835.

⁵ *J. Hyg., Camb.*, 1946, 44, 342.

⁶ *Ibid.*, 1945, 44, 179.

that such colleges shall receive grants on the same basis as teachers' training colleges or domestic science colleges, with similar conditions in regard to inspection, entry, and grant aid for students. The content of the child welfare course is summarized as being based upon "the study of the child at successive stages in relation to the family, including the physical, mental, and emotional development." Special shortened courses of not less than six months are planned for those already trained in some allied profession such as teachers, health visitors, hospital nurses, and certain categories of social workers. It is also suggested that nursery nurses holding the national certificate and with not less than two years' experience of work with children shall have some reduction made in the length of course for the higher "child welfare" qualification.

This new report will be studied with interest by those concerned with the care of the child. The confusion occasioned by the title "child welfare" should be resolved, for "maternity and child welfare" is long established and has a definite meaning in medical and lay circles. There is also the fundamental difficulty to be faced that the supply of girls, whether for nursing or teaching or for this new "profession," is limited; and to talk, as this report does, in terms of "a great many additional teachers," fully qualified to teach child care, is to disregard the realities of educated woman-power in terms of numbers.

THE SANITARY CONTROL OF ICE-CREAM

That freezing kills bacteria is a fairly common misconception. Actually there is no better method of preserving their life for long periods: this is true at least of all those which enter the body by the alimentary route. Ice-cream will therefore contain in the living state the original flora of its ingredients, which may include pathogens if any cream or milk enters into its composition, and—which is more important—those introduced by insanitary methods of handling. Outbreaks of intestinal infection conveyed by ice-cream have been numerous, and regulations have been in existence for some years requiring the registration and inspection of premises used for the preparation of ice-cream. Unfortunately the resumption of its manufacture after the end of the war has been followed by an extensive outbreak of typhoid fever at Aberystwyth due to the contamination of his product by a vendor who is a urinary typhoid carrier. A similar incident has recently been followed by an equally extensive outbreak of paratyphoid B at Coatbridge in Lanarkshire. In view of these occurrences it was evident that further statutory provisions were required, and the Minister of Health has now issued a Draft Order (Draft, dated Oct. 8, 1946, of the Ice-cream (Heat Treatment) Regulations, 1946), the effect of which, in short, is that the mixture of which ice-cream is composed must be pasteurized before freezing. It may be heated either to 150° F. (65.5° C.) for 30 minutes or to 160° F. (71.1° C.) for 10 minutes. Further regulations govern the subsequent cooling process and the maintenance of a sufficiently low temperature thereafter. These requirements do not apply when a "complete cold mix powder" is used, supplied in air-tight containers and manufactured from previously heat-treated material: this may be made up with "wholesome drinking-water," and colouring or flavouring materials, fruit, nuts, or chocolate, may be added without subsequent pasteurization. In a Circular (183/46) of the same date the Ministry of Health calls attention to these draft regulations and points out that local authorities have already considerable powers in connexion with the manufacture and sale of ice-cream under the Food and Drugs Act, 1938, and refers to the possibility

of defining bacteriological standards to which the ice-cream shall conform. Although it has been represented to the Ministry that laboratory tests of cleanliness are desirable, the conclusion reached is that "no test has yet been devised of the safety of ice-cream, and there is no test which would be sufficiently reliable for use as a statutory test of its contamination with non-pathogenic organisms." In the present state of knowledge of the subject it might well be premature to define statutory tests, but a very good idea of the hygienic quality of ice-cream can be obtained by performing a total bacterial count, a coliform count, and the identification of the coliforms of excremental type or otherwise. The performance of some such tests on the future heat-treated product may indicate whether the new regulations afford an adequate safeguard. The neglect of elementary precautions in handling and in ensuring the cleanliness of utensils may still presumably lead to serious contamination, if only on a reduced scale.

THE SPREAD OF POLIOMYELITIS

The mode of transmission of the poliomyelitis virus is a matter that is still unsettled. In the absence of definite knowledge whether the infection is conveyed by something inhaled or something ingested it is difficult to frame regulations for prevention, and the account (Aug. 17, p. 233) we gave recently of precautions to be taken in the event of an outbreak naturally takes each possibility into consideration. One way of studying this question is by seeking to identify the portal of entry by histological methods. Neurotropic viruses are known to reach the central nervous system by way of peripheral nerves, and their pathways can be traced by the lesions, consisting of nerve cell degeneration, leucocytic infiltration, produced both in peripheral ganglia and in the related nuclei in the brain. However, in the case of the latter particularly it is always possible that involvement is the result of spread from a neighbouring area, and such findings have therefore to be interpreted with caution.

An elaborate and painstaking study of this kind was described by H. K. Faber and Rosalie J. Silverberg,¹ who described material consisted of eight fatal cases of poliomyelitis occurring in San Francisco during 1943-4. In no case was there any evidence of involvement of the olfactory system—an interesting result in view of the belief prevailing until about 10 years ago, and of the efforts made in the U.S.A. to prevent ingress by this route by tanning the olfactory mucosa. The sympathetic system in both lower and upper levels and the gustatory system were occasionally involved; the visceral afferent pathways via the ninth and tenth cranial nerves were markedly affected in the cases, as shown by lesions in the petrosal and nodose ganglia and the solitary nucleus; but the most consistently infected pathways were the trigeminal, lesions being found in almost every case in the Gasserian ganglion and their central connexions. This type of evidence therefore suggests strongly that the pharynx is at least a common portal of entry: as the authors point out, it is a receptacle both for nasal secretion and for material ingested. It is therefore as uncertain as before whether the mode of transmission is by ingestion or by inhalation.

The annual general meeting of the Research Defence Society will be held at 26, Portland Place, London, W., on Wednesday, Oct. 23, at 3.15 p.m., when Prof. N. Hamilton, Fairley, M.F.R.S., will give the fifteenth Stephen Paget Memorial Lecture entitled "Wartime research in malaria and other tropical diseases of military significance."

IMPRISONMENT UNDER THE JAPANESE

.BY

A. P. CURTIN, M.R.C.S.

Late Surg. Lieut.-Cmdr., R.N.V.R.

read with interest the article by Capt. A. L. Cochrane (Feb. 23, 1942) on the effects of the psychopathology of imprisonment of ex-prisoners of war from Germany. It may be of interest also to review the main underlying factors, and the background of events that caused them, which contributed to the mental state of prisoners liberated from Japanese camps. All the conditions mentioned by Capt. Cochrane as operating in German camps were present but to a more marked degree in prison camps in the Far East. Only the medical officer who actually had care of these men and shared in the trials, difficulties, and unishments of their daily life in captivity can thoroughly understand them. I write mainly from experience of conditions in work camps in industrial areas of Japan, such as Tokyo. They varied in degree, but in the main the general trend seems to have been the same in all of them. The prisoners included British, Australians, Americans, Dutch, and Eurasians, their ages varying from 15 to 60 years.

On arrival at the Japanese port prisoners were grouped into parties or despatch to different work camps in industrial areas. In most instances the officers originally in charge of the men in the field were separated from them and sent elsewhere, and other officers, very often of entirely different nationality, were appointed. As a result doubt and mistrust were engendered in the minds of the men whether their new officers would, in fact, take any interest in their welfare and would stand, so far as it was possible, between them and the brutalities of the Japanese. The policy of the Japanese was to maintain small camps of not more than 350 prisoners, so that a very close watch could be kept on them by frequent roll-calls and "shake-downs," in the early days even during the night. Escape was out of the question, even had it been possible for a white man to pass unnoticed in the streets in Japan; in fact, no thought of escape occurred to the prisoners in these circumstances.

Food and Clothing

Food was scarce and greatly lacking in essential proteins, fats, and vitamins. The staple diet was rice and root vegetables or soyabeans made into soup, with occasionally fish and seaweed and grass when nothing else could be had. It never averaged more than 1,500 to 2,000 calories a day for the working men. On certain details—e.g., unloading box cars at a railway siding—the men were able to supplement their rations by stealing. This was also practised by the Japanese and seemed a habit in Japan in all branches of industry; indeed it appeared to be necessary for survival. Undoubtedly it was by this means that many prisoners held on to the threads of life, especially during the winter months. The motto was, not to get caught by the Japanese guards, or, failing this, if possible to come to some sort of compromise by giving them a part of the stolen food or loot. Punishment meted out to prisoners who were caught with stolen goods was severe and ruthless.

Many prisoners made small articles such as rings, belt buckles, etc., at the factories for the Japanese bosses, for which they were paid in rice and cigarettes. Red Cross parcels were few. Most camps received only three or four per man throughout the 3½ years. When, however, Red Cross food had been distributed stealing among prisoners themselves greatly increased. The sick had the same fare as those going to work, and it was difficult, at times almost impossible, to coax them to eat the unpalatable diet and to prevent them from giving part at least of their food away to other prisoners, many of whom in their state of hunger befriended the sick only to steal or be given their rations.

It was noticeable that while the men were kept in a state of semi-starvation sex presented a very minor problem and homosexuality was practically non-existent, except possibly in the galley, for the cooks always managed to supplement their rations. Sex talk and homosexuality were always likely to arise with any improvement in the rations.

The lack of clothing, particularly warm clothing, was responsible for a good deal of sickness during the winter months. In the early days men waited to take the garments of the dying for themselves, as they were in rags. In wet weather clothes had to dry on their owners, as each man had but one set. Only in the first winter of 1942-3 was any heating provided in the barracks. Many men were without shoes and had to go to work with sacking tied round their feet or in wooden clogs. Another problem was the struggle to keep clothing reasonably free from lice, which abounded. Bed bugs and fleas were everywhere and bug rats ran riot at night in the camp.

In winter, because of lack of blankets, the men were allowed to sleep in pairs to conserve as much warmth as they were able.

Tradition of Punishment and Work

Although the Japanese record is lightened by deeds of kindness extended to captives by individuals, the military and the police had been following their own vaunted tradition and practices reaching back to the primitive ages. Their motto for prisoners was that good workers have good spirits, and this was based on a continuous tit-for-tat of work and punishment. Fear of the latter was constant among the men and became to them a very real thing. Officers were treated the same as the men; there was very little discrimination. Most of the maltreatment of prisoners seemed to be carried out by the Gunzakus, or so-called civilian division attached to the army, who nevertheless wore military uniform and carried side arms. Punishments, which were inflicted for little or no excuse, included severe beatings, standing to attention in the open in all weathers for long periods, and solitary confinement. The severity of the punishment varied with the mood and particular tantrum of the Jap concerned at the time. Often it would result in black eyes, broken ear-drums, laceration of the scalp, broken ribs, etc. Prisoners' teeth were knocked out, the Japanese using their fists, leather or wooden shoes, belt buckles, and wooden swords.

The type of work varied according to the different working parties, some having relatively light work compared with others. Much of it, however, was particularly unpleasant and detrimental to the prisoners' health—e.g., work on crushing machines in a brick factory; shovelling coal, iron ore, copper ore, etc., in the closed-in holds of a ship where the concentration of dust and particles of the mineral was choking. Despite protests about employing men in this type of work very little notice was taken, and the more unpleasant forms of labour to which even the Japanese coolies objected were inevitably allotted to the prisoners. The average daily hours of work were from 7.30 a.m. to 5.30 or 6 p.m. Some parties had considerable distances to walk to and from work.

The Japanese tried many and varied devices to get as many men as possible out to work. They beat them, making life as unpleasant as possible for the sick in camp so that they wanted to go out to work at any cost to avoid this persecution. Then, by supposed order from Tokyo Army H.Q., all sick men, even the factory injured cases, were ordered to go on half rations, and, as men unable to work, they were not allowed to buy or to receive extra comforts, such as cigarettes or cookies when they were available. The very few Red Cross food parcels were allocated to working men only. Many of these devices, fortunately, were cunningly overcome in one way or another, and so failed to achieve their desired object.

It was a long time before a regular day off (and then only one day a month) could be obtained for the working men in order to give them a chance of a rest and to wash and mend their clothes. Another concession eventually obtained in some camps was that men over 50 years of age were not employed on heavy work, only on cleaning the camp or other light work. There was a vicious competition between commandants of the various work camps in the industrial areas to see who could maintain the highest working percentage. One of my camp commandants during the period he was with us devoted the whole of his time to compiling work graphs of different camps in the area, and the walls of his office were covered with them. Prisoners were made to work as stevedores at night if the company concerned presented the camp commandant with a gift of "saké" or beer so that he could hold a drunken party for the camp staff.

Only a very few sick men were allowed to be left in camp during inspections by Japanese Military Staff from Tokyo. The others were hidden somewhere in the camp compound or, if they couldn't walk, were carried out to work by their friends and hidden in some part of the factory. In this way an entirely false picture of the sickness in the camp was presented. The food improved somewhat on inspection days, but these were not very frequent. Extra clothing was also issued occasionally but had to be turned in again after inspection. Needless to say, no communication was allowed between officers among the prisoners and the Japanese visiting military staff.

Medicines and the Sick

Medicines were most difficult to obtain. The Japanese medicine "black market" was flooded with cheap German products, mostly made up in ampoules to be given by injection. If there happened to be a useful drug in some of these preparations the quantity was so small that the preparation was relatively ineffective in the dosage prescribed on the label. Most of the medicine used in camps was bought with the pay given to the officers by the Japanese and obtained through the "black market." Allocation of medicine and medical supplies by the Japanese Army H.Q. to work camps was totally inadequate, and most of this was stolen or used by the Japanese staff for their own purposes. Much of the surgical gauze appeared to find its way eventually to the geisha house, although for what purpose I was at a loss to determine.

PENICILLIN

in
Dermatology

THE local application of penicillin, or a combination of local and systemic administration in more serious infections, has given striking results in most skin diseases due to Staph. aureus and to Str. pyogenes.

In the form of an ointment containing 500 units per gm., and also as an aqueous spray, penicillin has given valuable results in Sycosis barbae, impetigo, recalcitrant eruptions of the hands and feet, boils, carbuncles, erysipelas, infectious eczematoid dermatitis, otitis externa, blepharitis and tropical ulcers.

To be sure . . .

Specialisation in sutures over the last sixty years has given Johnson & Johnson a leadership which is literally world-wide. Take, for example, their Ethicon Non-Boilable Catgut Sutures. These, as taken from the sterile tubes, have more tensile strength than is required to ligate the largest human blood vessel or to suture the most dense human tissue. It is interesting to record that Johnson & Johnson are Sole Agents for the new biologically inert Surgical Metal—Tantalum. Ethicon Tantalum Sutures are likely to play an important part in surgery of the immediate future.

Reports of Societies

THE PROBLEM OF DISSEMINATED SCLEROSIS

In his presidential address to the Section of Neurology of the Royal Society of Medicine on Oct. 3 Dr. DOUGLAS McALPINE dealt with the problem of disseminated sclerosis. No neurological disease, he said, had until recently had so much attention from clinicians, pathologists, and bacteriologists, yet its true nature still eluded them. This subject ought to be reviewed once again in the hope of arousing fresh interest in a problem which, on humanitarian grounds alone, deserved the attention of those qualified to take part in its investigation.

Aetiology of the Disease

The term "disseminated sclerosis" was inadequate because it failed to describe either the essential nature of the disease or the type of initial lesion. Dawson, in considering the various possibilities, concluded that disseminated sclerosis was due to a specific morbid agent, probably a soluble toxin, which was conveyed to the nervous system by the blood, and that the occurrence of remissions and relapses compelled the assumption of the morbid agent in the body. No worker had produced evidence to contradict the conclusion that disseminated sclerosis was a form of acute or subacute disseminated encephalomyelitis due to a blood-borne infection. Russell Brain, in a critical review published in 1930, discussed the various attempts made during the first part of this century to isolate a specific organism from the nervous system in fatal cases and to transfer the disease to animals, and he showed that these attempts had either failed or had been inconclusive. Repeated failures to transmit the disease to animals had caused renewed doubt about its infective nature. In America Putnam concluded that venous thrombosis was the essential histological lesion, but it was doubtful whether the results of Putnam's work could be applied to the problem of disseminated sclerosis, and it was difficult to visualize thrombosis as the primary lesion in view of the clinical fact that the duration of symptoms might be exceedingly brief. On the other hand, there were facts which suggested that the vascular mechanism might occasionally come into play.

There remained for discussion, said Dr. McAlpine, two further lines of approach which were interrelated: (1) that allergy might be a factor in disseminated sclerosis, and (2) that the disease might be caused by a bacterial agent or by a filter-passing virus. There were certain features of disseminated sclerosis, notably the relapsing nature of the disease, which could be explained on the basis of allergy, but at present further speculation on this point would serve no useful purpose. Efforts made by the bacteriologist to establish the nature of the causal agent had up to the present failed. While final judgment must be reserved on the possible role of a toxin, these negative findings seemed to point to a filter-passing virus rather than to a bacterial agent. This was perhaps borne out by some recent work in Moscow, not yet published in this country, which claimed the first success in isolating a virus from a human case and the production of the disease in animals. The further results of this work, which was still being pursued, would be awaited with great interest.

If it was assumed that disseminated sclerosis was toxic-infective in origin, there remained for consideration the mode of infection. At the beginning of this century attention was focused on the peripheral nervous system as the probable route. More recently the experimental work on poliomyelitis in monkeys had suggested that in these animals the virus travelled via the axis cylinders. After discussing various theories Dr. McAlpine considered that there was good evidence to support the view that from a focus in the skin bacteria and their toxins or a virus might reach the nervous system either by neural pathways or by the bloodstream.

The Clinical Approach

In discussing the clinical approach to the problem Dr. McAlpine limited himself to those features of the disease which seemed to throw some light on its causation. Unlike the majority of organic nervous diseases, disseminated sclerosis

was distinguished by the remarkable variation in its clinical course. Remissions might last for more than ten years or for less than six months. The degree of recovery might vary within wide limits. For example, the disease might appear in a florid form, but despite the multiplicity of signs, good clinical recovery and lengthy remission might follow. Age modified the course of the disease. The older the patient the more localized were the signs and the more chronic the course. When the disease first attacked an individual in the fifth decade of life the remissions were as a rule inconspicuous, the disease tending to run a slowly progressive course interrupted by short periods of arrest. The florid form of the disease was seldom seen outside the younger age groups.

Despite its protean nature, the disease had been recognized by the clinician and the pathologist as a clinical entity, though the term "disseminated sclerosis" might cover more than one type. The peculiar nature of the disease could be explained in terms of the patient or of the agent. As there was no precise knowledge of the character of the agent, it might for the moment be assumed that the reactions of the individual to the disease were the prime factor in modifying its course. It could be inferred that the clinical features of disseminated sclerosis were in all probability the result of an immunity to infection which varied not only from case to case but also during the course of each patient's illness. In conjunction with the abnormal findings in the cerebrospinal fluid, this view lent support to the theory of a toxic infection. If it was assumed that this infection was due to a virus it would be necessary to broaden their views as to the symptomatology of the disease and to recognize the existence of sub-clinical forms.

A Survey of 124 Cases

Dr. McAlpine showed a table indicating the age of onset and the sex incidence in relation to two common types of disseminated sclerosis as observed in 124 cases during the past year. The number was too small for statistical value, but certain facts seemed to emerge.

Age Group	Relapsing		Chronic Progressive		Percentage
	M.	F.	M.	F.	
10-20	8	10	—	—	14.5
20-30	18	32	—	—	40
30-40	12	19	3	4	31
40-50	1	6	3	6	13
50-60	—	—	—	2	1.5
	39	67	6	12	

In this country it was generally held that the disease was more common in females, and the above series, though small in number, seemed to bear this out, more particularly in regard to cases in the fifth decade. In other European countries and in America either males predominated or there was no significant sex distribution. Occupation appeared to play no part in causation. Both urban and rural dwellers might be affected. There appeared to be no seasonal incidence in this country. The number of authenticated cases of familial disseminated sclerosis was not large, but there could be no doubt that the disease might attack more than one member of a family. Out of a total of 142 cases (124 of which appeared in the above tabulation) there was a familial incidence in 8 (5%); in 6 the disease affected siblings, and in one case the father and in another the mother of the patient had been affected. This familial incidence seemed to indicate an occasional hereditary predisposition to the disease, and in this respect the position might be compared with tuberculosis.

No distinctive type of body build or colouring seemed to be associated with the condition, though obesity appeared to give some protection. Approximately 20% of the patients in the series stated that they felt run down before the illness began. In 71 cases an approximate idea of the diet had been obtained, but only in 10 were meals ascertained to be irregular or deficient in quantity, and in no case was there evidence of malnutrition. The impression obtained was that the individual when first attacked was generally in good health, though in a minority some interference with health or with diet might have lowered the resistance. In only 8 cases was there a history of any fever—usually described as "influenza"—within a month

of onset, and in only 5 other cases a history of "cold and sore throat" without fever. A positive history of peripheral sepsis within one year of the onset was obtained in 18 cases. The known bacteria associated with sepsis might play no direct part in the causation of the disease, but the possibility of secondary virus infection was not excluded.

Conclusions

Dr. McAlpine summarized his conclusions as follows:

Inheritance plays only a minor part in the aetiology of disseminated sclerosis, and therefore the choice seems to lie between biochemical or enzymic abnormality, of which proof is so far lacking, and, on the other hand, a toxi-infective process. Increasing knowledge of the various forms of encephalitis in man and animals and the part played by viruses in certain of them, when viewed against the histological background of disseminated sclerosis, suggests that this disease is also infective in origin. The results of the clinical approach bring to light no facts which are contrary to this view and some which seem to favour it. With the exception of cases in which there are influenza symptoms, the onset of the disease is not generally accompanied or preceded by constitutional symptoms. The possibility then arises that invasion of the nervous system and the appearance of the first sign of the disease may not always coincide in time, but that the former may take place months or years previously, as in rabies or syphilis. At what point in the patient's life history did the nervous system become infected or sensitized? In this inquiry there was no answer to that question.

Attention was next turned to the portal of entry of the hypothetical agent or toxin, and by analogy with other infections of the nervous system it was inferred that the skin and the alimentary tract were the likeliest starting-points of the invader. From our knowledge of the histology of disseminated sclerosis it was necessary to postulate a haematogenous spread from the focus. The evidence in favour of the skin as an occasional portal of entry in disseminated sclerosis is purely circumstantial, but it seems to warrant further exploration in view of the part played by the skin in other infections of the nervous system. The remaining portal of entry is the alimentary tract. Should disseminated sclerosis prove to be of virus origin, then, by analogy with acute poliomyelitis, the alimentary tract becomes a potential source of infection. The fact that a history of intestinal disorder is rarely found in these cases must not be regarded as a reason for dismissing that possibility. The proof of a virus infection, whether by direct or indirect means, would be of the greatest help to future progress in our knowledge of the disease and its treatment, and there is urgent need for carefully planned research work based on the close co-operation of the clinician and the bacteriologist.

Sir CHARLES SYMONDS, in proposing a vote of thanks for the address, congratulated the President on his choice of subject. There could be no problem which so often excited the curiosity of the neurologist and so constantly left him in a state of despair. The vote of thanks was seconded by Dr. ANTHONY FEILING, who said that the President had given a masterly survey of the subject, with some very valuable hints as to the possible future approaches to the aetiological problems.

ELECTROENCEPHALOGRAPHY

The autumn meeting of the Electroencephalographic Society, held at the Maudsley and Runwell Hospitals on Oct. 4-5, was attended by a number of European workers, including Professors Baudouin, Colle, Fessard, Frey, and Monnier.

In opening the meeting, the President, Prof. E. D. ADRIAN, said: "Apart from the value of the contributions which they are able to make to this meeting, the visit of our European colleagues has a more important significance in that it enables us to confer on the standardization and interpretation of results and to agree on the various criteria which we all have to apply in the interpretation of records. If we are to attempt to bring electroencephalography to an exact science, it is essential that we formulate common standards and common terms which will form the basis of an international E.E.G. language."

Among the papers read were: "A New Six-channel Electroencephalograph," W. A. Cobb; "An Electronic Analyser for E.E.G. Recording," W. Grey Walter; "The E.E.G. in Psychopathic States," J. D. N. Hill; "The E.E.G. after Pre-frontal Leucotomy," G. D. Greville and R. Ström-Olsen; "Cortical Correlates of Sensory Stimulation in a Patient with Myoclonus," G. D. Dawson; "La Première Réunion d'E.E.G. de langue française," A. Baudouin. Arrangements are being made for the publication of these papers in appropriate journals where possible.

Correspondence

R.M.B.F. Christmas Appeal

SIR,—Christmas once again draws near and it is time for the hospitality of your columns to launch our Annual Christmas Appeal on behalf of the poor beneficiaries of this Fund. The reasons for this appeal are now well known to all readers and there is no reason to stress them again. I would rather emphasize the point that they are as cogent as ever. It is true that the Old Age Pension which is now in force, making the financial position of old people more bearable, whereas previously it was quite intolerable—still means the actual increase in annual income is only £41 12s. 0d. when bearing in mind the tremendous increase in the cost of living still makes the position of the poor housewife very difficult indeed. Further, very many of our beneficiaries are over 70 years of age and so not able to draw the O.A.P. There is that very real sense of being "not forgotten" at a festive time of Christmas, and the knowledge that our Christmas Gift will ensure the purchase of a few extra luxuries will just make all the difference.

I recall that my appeal last year for £2,000 to enable the Fund to give £4 to every beneficiary—a record sum for which I scarcely dared to hope—actually reached the grand total of £2,127, and I know every generous donor will feel amply repaid by the gratitude and pleasure these gifts evoke. I venture to plead for a similar sum this year? I feel sure that although I well recognize that times are very difficult for everybody just now, the still greater difficulties and anxieties of very poor brethren will not pass unheeded.

—Please forward contributions marked "Christmas Gifts" to the Secretary, Royal Medical Benevolent Fund, 1, Beaufort House, Manor Fields, Putney, London, S.W.15, who will gratefully acknowledge.—I am, etc.,

ARNOLD LAWSON
President, R.M.B.F.

Classification of Psychological Disorders

SIR,—Sir Charles Symonds (Sept. 21, p. 436) has effectively drawn attention to the lack of necessary discrimination between the terms Dr. Dalton Sands employs in his article on "Electroconvulsion Therapy in a General Hospital" (Aug. 31, p. 2). He uses, for example, "anxiety state" and "anxiety neurosis" without definition or a distinguishing description of the conditions referred to. In particular it should be recognized that "anxiety," which enters so frequently into Dr. Sands's title, is not a simple unit factor. It is, as commonly found, a complex reaction which may include elements of guilt and tension from aggressive impulses, for instance, apart from pure anxiety.

The article provides another illustration of the fact that statistical studies on psychiatric disorders, in the present state of knowledge, are very apt to be misleading unless it is made clear that the conclusions drawn merely indicate tendencies and do not constitute a positive addition to knowledge. I am, etc.,

London, W.1.

FREDERICK DILLON

Errors in Regard to Goitre

SIR,—The article entitled "Some Vulgar Errors in Regard to Goitre" by Linnell, Keynes, and Piercy (Sept. 28, p. 4) was indeed refreshing to read, after the recent spate of literature on the medical treatment of thyrotoxicosis with thiouracil. It is not my intention to attempt to enter into a debate as to whether treatment will eventually displace surgery in the treatment of toxic goitre, except to say that at least surgical procedure has stood the test of time. I would wish to comment briefly on some of the points raised in the article. Surgery is the only safeguard and prophylaxis against the later changes which may take place in a goitre, and operation is thus a means of preventing much ill-health and suffering. There is also the cosmetic aspect, as most women are worried about an obvious swelling, the days when "Rossetti" necks were the fashion having passed.

The indiscriminate use of iodine cannot be too strongly condemned. Not only is the patient buoyed up with false hope

but he is ultimately left in a far worse condition for radical surgical treatment or for the administration of thiouracil. The profession should in my opinion avoid using iodine altogether, except as part of the preparation for operation. The late Cecil Joll, whom I assisted for many years, strongly deprecated its all too common and thoughtless use. To embark on thyroid surgery without serving a long apprenticeship is wrong, as the hazards encountered are many. Joll himself often said that he assisted at some thousand-odd operations for goitre before undertaking one himself. Linnell *et al.* rightly consider the importance of good anaesthesia, without which the operation may be one of extreme difficulty in the most capable hands. All would-be thyroid surgeons should not fail to read Rowbotham's book *Anaesthesia in Operations for Goitre* (Blackwell, Oxford, 1945), for therein lies much sound guidance and wisdom. Lastly the co-operation of physician, surgeon, ear, nose, and throat surgeon, and anaesthetist is the ideal before the final decision as to the best form of treatment is made.

Let us not forget that many thousands of sufferers from goitre and its complications have obtained lasting relief from a well-planned and skilfully executed operation.—I am, etc.,

Aylesbury.

RALPH H. GARDINER.

Treatment of Ingrowing Toe-nail

SIR,—The operation for ingrowing toe-nail described by Dr. J. Hume Stewart (Sept. 7, p. 329) is ingenious. And that seems to me to be its fault. It is too complicated and ingenious an operation for a minor disability, involving as it does a minimum of seven days in bed for the patient. Furthermore, the cosmetic result is obviously not perfect.

In my own experience the simplest and most satisfactory procedure is that described by Dr. P. F. Chapman (*British Medical Journal*, 1934, 2, 1073). This consists in paring a groove down the centre of the nail with a piece of broken glass. The groove then forms a hinge on which the affected side of the nail is lifted up so that it comes to lie above the granulation tissue. A small strip of petroleum jelly gauze may be packed under the nail. Since 1938 I have made use of this operation exclusively in all cases of ingrowing toe-nail that have come under my care both in civilian and in military practice. A soldier may be allowed three or four days in hospital, but a civilian, with his wider choice of foot-gear, may be treated as an out-patient and has no need to lie up. Chapman's operation is so simple, so satisfactory, and at the same time so little known—none of my surgical colleagues in the Forces to whom I introduced it had heard of it—that I hope these few words in its favour will not be thought out of place.—I am, etc.,

Southwold.

J. C. LEEDHAM-GREEN.

Is Thiamine the Antineuritic Factor?

SIR,—As one who has followed with deep interest the many reports now available on the deficiency states affecting the prisoner-of-war in the Far East—an interest naturally stimulated by one's own investigations of nutritional retrobulbar neuritis in Nigeria before the last war—I am tempted to ask now how far we are justified in still calling thiamine the antineuritic factor.

In West Africa in 1937, when I returned to Nigeria after my retirement from the Colonial Medical Service, I carried out an extensive series of trials with autoclaved marmite, in high dosage and over a period of months in each case, on this visual condition, with the object of excluding thiamine as a curative factor. I would mention that in all these cases routine ophthalmic tests (excepting scotomata tests) were always done to exclude other disease and gross refractive errors in order that one might be certain one was dealing only with a nutritional defect. The result of these trials convinced me beyond doubt that the curative factor was attributable to the autoclaved marmite or yeast, and not therefore to thiamine.

The opinions of those medical officers sharing captivity with the P.O.W. case has confirmed this in another way, for they have shown that thiamine did not protect these men from this condition. Nor do they accept beriberi clinically as the cause. No one, I think, disputes thiamine as the anti-beriberi factor, and indeed the recorded experiences of these medical officers referred to fully confirms its effect on wet beriberi.

Research references to beriberi in this country, before the war, have appeared simply to accept this disease as the only one which could occur following a rice dietary. Yet, as has been so amply demonstrated by the P.O.W. case, and in Madrid, a multiplicity of B deficiency states can be produced. There have, however, been a number of research nutritionists who disputed whether thiamine is, in fact, a true organic neuritic factor; and most of them agree it is not concerned with central neuritides. Vedder, in 1943, has shown the danger of accepting rice as merely deficient in Vitamin B₁. He has quoted Ackroyd's work as well as his own, and he considers that the clinical picture of dry beriberi as it occurs on a rice-eating diet, with its nerve and cord degeneration, is caused by a complicated vitamin deficiency. It seems obvious that the so-called polynuritis of chicks is hardly a true neuritis, with their sudden recovery when given thiamine. Elvejehm (Eddy and Dalldorf's, *The Avitaminoses*) has suggested it is primarily a condition of disturbed carbohydrate metabolism rather than lesions of the nervous system. It is certain that other vitamins than B₁ play a most important part in these neuritic conditions, and definite proof of this has been forthcoming. To continue to accept thiamine as the antineuritic factor seems, therefore, hardly tenable in the face of such evidence.—I am, etc.,

Cheltenham.

D. FITZGERALD MOORE.

Diagnosis of Intestinal Amoebiasis

SIR,—I have yet to see in recent accounts of amoebiasis a mention of the use of "provocative emetine" as an adjunct to diagnosis. Such a method was generally well known in the Services and in many cases was used as routine in suspect but unproven cases. The method consists of the administration of emetine hydrochloride 1 gr. (65 mg.) intramuscularly—or emetine bismuth iodide 3 gr. (0.2 g.) orally—the night previous to the faeces examination. The following morning a purge is given and the stools examined by the usual methods. The effect of the emetine is provocative or stimulatory to the trophozoite, with the result that a patient suspected of latent amoebiasis and producing a series of negative stools may well produce an immediate positive result.—I am, etc.,

Newcastle-upon-Tyne.

K. R. HILL.

Penicillin Injections

SIR,—I was under the impression until recently that when giving penicillin injections the syringe should be sterilized by boiling or autoclaving, as spirit would inactivate the penicillin. However, Prof. Berry, in Sir Alexander Fleming's book on penicillin (p. 50), says that penicillin is not inactivated by solutions of ethyl alcohol up to 25%. In general practice it wastes a lot of time to boil the syringe each time, and I am now using syringes sterilized in 70% industrial spirit. The solution of penicillin as made up with sterile water or saline would only contain a trace of alcohol—certainly nothing approaching 25%.

Regarding the oily injection of penicillin, I would be interested to know how quickly a trace of water in the ampoule causes deterioration in the bulk of the penicillin left. If this deterioration takes several weeks, one would not need to be so very careful about drying the syringe used to withdraw the separate doses, provided the ampoule was used within a week or two.—I am, etc.,

Bristol.

P. FINCH.

Perforation of the Ileum in Enteric Fever

SIR,—With reference to Dr. G. E. Dunkerley's article on "Perforation of the Ileum in Enteric Fever" (Sept. 28, p. 454), I had the unusual experience of encountering two such cases within two weeks in a small epidemic of six cases seen at a military hospital in M.E.F., and append very brief clinical notes which may be of interest.

This first man had been ill five weeks with typhoid and was in his second relapse and had been complaining of acute abdominal pain for sixteen hours. On examination he was a patient in *extremis* with generally rigid and tender lower abdomen and cold extremities. At operation the pelvis was full of purulent fluid and the ileum, some two feet from the ileo-caecal valve, showed perforated ulcer with protruding

slough. Recovery followed suture with pelvic drainage and careful post-operative treatment including continuous gastric suction, adequate intravenous fluid therapy, and regular morphine.

The second man was in the second week of illness and was seen half an hour after the onset of violent lower abdominal pain. On examination he was writhing in pain with the knees drawn up, tender in both flanks, and showing marked rebound tenderness in both areas. There was no true rigidity, but a somewhat surprising finding was the hearing of vigorous audible peristalsis. Half an hour later he developed definite localized rigidity in the right iliac fossa. Laparotomy was not delayed and suture of a friable perforation one foot from the ilio-caecal junction was undertaken and omental graft brought down. A considerable quantity of clear fluid was sucked from the pelvis, and abdomen was closed without drainage. The lower end of his wound suppurated and a large pelvic abscess developed, both conditions slowly resolving in three weeks. He then proceeded to have a relapse of his typhoid fever, which happily was an uncomplicated course.

The unusual features were the very high incidence of perforation in this small epidemic, and the rather surprising recovery of the first case, which might suggest that this complication, especially if diagnosed early and given adequate surgical care, is not so lethal as hitherto supposed.—I am, etc.,

London, N.21.

W. GARDEN HENDRY.

Giant Urethral Calculus in the Female

SIR,—With Mr. Norman Lake's article in the *Journal* of Sept. 7 (p. 328) fresh in my mind, I went the following morning to see an old lady of 70 in consultation, with Dr. Charles Sims of Exeter. Apart from the patient being somewhat older, her symptoms and physical signs closely resemble those described by Mr. Lake. The calculus, after removal in the manner Mr. Lake describes, measured 6.7×4.6 cm. with a circumference of 17.7 cm. in its long axis. Its colour and somewhat irregular surface closely resembled that of a potato.—I am, etc.,

Exeter.

P. M. G. RUSSELL.

Health Service Bill

SIR,—From its inception I have been opposed to the National Health Service Bill as I consider that it interferes too seriously with the responsibility and liberty of the individual doctor, which is such a strong factor in the safety of the patient. Study it as I may, I cannot see in what way the State medical service Bill improves so much upon the existing medical services as to warrant this sacrifice. Further, are the existing medical services so bad as to merit the expenditure of so much time in Parliament and of public money upon this State medical service during these critical years? Surely to an honest observer the reply must be in the negative. One is forced then to conclude that the State medical Bill is no health measure at all but a political measure.

I could not agree more completely with Dr. Sybil Tremellen and Drs. Zoë and Paul Harris in their letters (Sept. 21, p. 439). Medical practice is my life, but I will not enter this State medical service; and if I can then no longer make a living as medical practitioner I shall have to find something else to do. It would be far more difficult for me to make this decision had I a wife and young family or any other dependants to support; but it is my considered opinion that if we English men and women do not now, and at every similar issue, refuse to yield right to expediency, we shall find too late that we have sold our birthright for a mess of pottage, and that we are treading the road the Germans trod.—I am, etc.,

Walton-on-the-Hill.

URSULA M. DICK.

SIR,—Dr. Peter Waddington (Oct. 5, p. 515) charges me with lack of political insight in comparing Socialism with Nazism. As a matter of fact my letter made no such comparison. What I did contend was that the surrender of individual thought, and a blind acceptance of whatever thinking the State chooses to do, were the attitude of mind which led to the Nazification of Germany, which is a very different matter. He suggests that I deplore the fact that a Labour Government was returned to power by less than one-half of the electorate, whereas what I actually do deplore is the nauseating attitude taken up by so many Socialists that they have an overwhelming mandate

from the country when, in fact, they have not. Dr. Waddington queries my suggestion that the Bill gives the Minis dictatorial power. I can only think that he has not read the Bill, or that he is imperfectly acquainted with the procedure by which a Minister makes regulations.

Dr. Waddington appears to use the word "strike" reference to a possible refusal on the part of any doctor participate in the scheme. This is a curious attitude of mind. If the Government in due time offers us a contract which find unacceptable we have every right to decline to enter into that contract. This hardly savours of a "strike"—or is it reprehensible in Socialist eyes to venture to differ from Government that it constitutes one?—I am, etc.,

Hove.

NORMAN MAPLE

Universities and Outside Committees

SIR,—Serious misgivings have been felt and expressed regarding the position of the universities in relation to outside "Committees," so many of which have blithely made recommendations to Government Departments which have appointed them; and even when these recommendations seriously affect the educational autonomy of the Universities, they have been adopted by Government Departments without reference either to Parliament or the universities concerned. This tendency is criticized as obviously threatening academic freedom in the *Times Educational Supplement* (Sept. 21, 1946), both in its editorial and in an independent article. It is pointed out in the editorial that "the maintenance of academic freedom has in this day acquired a new significance," and the article presses the need for "a united front to preserve university independence."

London University has experienced an example of this tendency to raise a report of a Departmental Committee practically to the level of a Cabinet edict. The Goodenough Committee, appointed by the then Minister of Health in March 1942, and reporting in May, 1944, recommended (1) that the medical schools of the universities should adopt the principle of admitting a reasonable proportion of students of both sexes (2) that the University should submit to drastic overhaul the medical curriculum (to be conducted apparently by a body wholly outside university jurisdiction). The Minister of Health, Mr. Willink, announced (*Hansard*, Jan. 18, 1945) the decision of the Cabinet to enforce by manipulation of the Exchequer grants to universities these two recommendations of the Goodenough Committee. At no time, as far as I am able to ascertain, were the universities consulted before this decision was published.

The medical schools of London University have accepted under protest, the recommendation imposing co-education. It has been pointed out by a highly responsible and authoritative medical corporation that the composition of the Goodenough Committee detracts from the respect which a committee wielding apparently such influence with the Government should command. The committee consisted of 10 members. There were 12 very famous medical schools of London University—of which one of these schools (University College) was represented in this committee, and that school had three representatives. The second recommendation affecting the curriculum constituted, in my opinion, an even more revolutionary breach of academic freedom: the preparation and ordering of curricula have hitherto been regarded as the inalienable right and duty of universities.

The governing bodies of the teaching hospitals in London, all of whom are schools of the University, find themselves present in an uncomfortably precarious position. The National Health Bill, which has passed its third reading in the House of Commons but is not yet law, makes a distinction between the teaching and the non-teaching voluntary hospitals as regards the independence of their management. The imperative necessity to secure the co-operation of the great teaching hospitals compelled the Minister (but with obvious reluctance) to leave a much larger measure of independence with the governing bodies of teaching hospitals as compared with the non-teaching hospitals. An illustration is offered of the predicament which the present uncertainty produces in the conduct of the teaching hospitals in the experience of the London School of Medicine for Women, with its parent hospital the Royal Free. The Goodenough Committee (see p. 119 of its report) pointed out that the University College Hospital, the Middlesex Hospital, and the

Royal Free Hospital occupy an area which is over-hospitalized, and declared that "the removal of one of these medical schools to another part of London may become advisable," and that "the London School of Medicine for Women should be the school to move." The committee further declared that "University College Hospital Medical School is in the most favourable position of any medical school in London," a view with which the three representatives of that school on the committee were probably in hearty agreement. The Governors of the Royal Free Hospital, with the co-operation of the London School of Medicine for Women, desire to purchase an adjoining site now in the market in order to erect a new permanent wing of the hospital, whose buildings were seriously damaged in the blitz. The question of removal seems to have been broached to the governors of the hospital by the University Grants Committee in November last, when the governors made it quite clear that they were opposed to this suggestion, and since that date it would appear that the Ministry of Health have refused to sanction the carrying out of any projects for the purchase of sites adjoining the Royal Free Hospital; the Ministry would appear to rest this action upon the dictum of the Goodenough Committee, quoted above.

I submit, Sir, that this is a situation which calls for the anxious consideration of the medical profession, and perhaps might engage the attention of the new group of the B.M.A. which deals more particularly with political matters.—I am, etc.,

House of Commons.

E. GRAHAM-LITTLE.

Royal College of Physicians of London

SIR,—Certain Members of the College have written to the medical journals about the representation of Members in the counsels of the College. They must know that the President took the initiative in calling a meeting of Members of the College in January. This was attended by three hundred Members and a committee was appointed to go into the matter. This committee reported to another meeting in April and their recommendations were accepted practically unanimously. The President thereupon brought the matter before the Council of the College, who made recommendations to the Comitia which involved alterations in the Bye-laws of the College, and this was put in hand at once. There is no reason to believe that the great majority of Members are not satisfied with the procedure adopted. A few Members criticized the method of election of Fellows but did not receive substantial support.—I am, etc.,

H. E. A. BOLDERO,
Registrar.

SIR,—If "Dum Spiro Spero" (Aug. 31, p. 313) finds his Membership of the College of Physicians a burden, he has a very simple remedy: he can resign it. When I had been a Member for 25 years: I wondered why I had failed to be elected to the Fellowship, and looked up the Bye-laws. Bye-law LXXV reads as follows.

"The Council, in determining the fitness of Members for nomination to the College for election to the Fellowship, shall take into consideration, in accordance with the Bye-law: standing in the College, academical honours, distinction in literature or science, professional eminence, public appointments, and social position."

In regard to the first five of these, my claims, modest though they were, were in my admittedly prejudiced view at least not inferior to those of many youngsters who were received into the charmed circle after only five or six years' Membership. I therefore concluded that I was defective in "social position," whatever that might mean; that I was in some way "socially undesirable" as they say in totalitarian states.

In June, 1943, I notified the Registrar of my wish to resign my Membership. He replied that the President wished me to take no action until he (the President) had discussed the matter with me. In due course the President invited me to see him. After a long discussion he asked me not to resign before the next election. To this I agreed, and suggested that I should submit a list of my publications. This suggestion was ignored. When in the following May I was again not summoned to receive the coveted Presidential kiss or embrace, or whatever form the accolade may take, I applied for and was graciously given permission to resign.

When my resignation became known to my friends many of them told me that had they only been aware of the injustice

which I had suffered they would have made representations on my behalf to members of the Council or other influential Fellows of their acquaintance. So numerous indeed were these kindly but belated offers that I was forced to conclude that "social position" was something acquired by the process of getting to know the right people. What surprises me is the seriousness with which my action is regarded by my friends. They tell me that I have "burnt my boats" and ruined my prospects of advancement, ignoring the fact that at my seniority I am beyond such considerations. My resignation has impaired neither my enjoyment of life nor my professional efficiency, such as it is. The College, beyond granting me a licence to practise (for which it was handsomely remunerated) six months earlier than I could have obtained it from my University, has not contributed one iota to my education. Its motto might well be *lucis a non lucendo*.

Having freed myself from the stigma of being a discredited Nestor among Members I have at least gained in self-respect. My only regret is the loss of £40 and the time and labour (wasted from an educational point of view) which I spent in cramming for the examination. If "Dum Spiro Spero" follows my example and ceases to indulge in the morbid luxury of giving way to his grief anonymously he will, I am sure, be a happier man.—I am, etc.,

Cambridge.

FF. ROBERTS.

Postgraduate Education

SIR,—Prof. R. W. Johnstone's reproach (Oct. 5, p. 510) that in compiling the account of the facilities for postgraduate education in your Educational Number the Colossus of London was allowed to dominate the picture is due perhaps to the mistitling of the article. The article on "Facilities for Postgraduate Education" was almost wholly concerned with the work of the British Postgraduate Medical Federation, which has its centre in London, although, as Sir Francis Fraser stated, it should become a source of information on postgraduate facilities in all parts of the kingdom. But in other portions of the Educational Number, under the general heading of "Medical Schools," references were made to postgraduate facilities and facilities for taking higher qualifications, and here certainly, in the amount of information afforded, the universities outside London were in no way overshadowed.—I am, etc.,

THE COMPILER.

Definition of Health

SIR,—I should like to comment on the definition of health adopted by the World Health Organization, as reported by Dr. Melville D. MacKenzie (Sept. 21, p. 428). Surely complete physical, mental, and social well-being is a godlike state, which we, being human and mortal, can hardly hope to attain, let alone claim as our right. Besides, if health is to be so described, being a complete state, it cannot be otherwise than as it is. Thus, the following paragraphs of the Basic Principles would be absurd if it was not usually recognized that health is a variable state. To quote Dr. Walter P. Kennedy (*Lancet*, 1946, 2, 427), "... health is a state of being and, as a biological phenomenon, is in a continual condition of flux. ... Health and disease are not a simple pair of contrasting opposites like heat and cold. They are made up of immense numbers of components involving the body, the mind, and the spirit. ... Health, then, is a state which can be measured."

I do not hope to influence the World Health Organization to change their definition, but I wish they had chosen the following: "Health is a balanced state of physical, mental, and social well-being, and not merely the absence of disease or infirmity."

—I am, etc.,

London, W.C.1.

W. F. FELTON.

Contamination of Bread

SIR,—Your annotation on rag flock (Sept. 28, p. 467) has these words in the last line: "... any kind of filling material. ..." It is about another and, I think, far more important filling material that I would beg to say a word or two. There are in my street more dogs and more children than in most streets; there are no gardens to the houses; the dogs and children share the roadway, footways, and gutters: the children prefer the roadway; the dogs have a preference for the footways, especially for depositing their excrement. At

the bottom of the street is a busy baker's shop to which bread is conveyed by motor-vans. This bread is transferred by means of large wooden trays from the motors to the shop, and it is quite a common happening for loaves to fall off the trays both outside and inside the shop. To save space I leave the rest to the imagination of the reader.

Now that there is more paper available, *vide* the enlarged news-sheets with their miles of printed piffle and advertisements, would it not be a matter for the attention of that "red" hot health crusader, Mr. A. Bevan, to see that all bread is wrapped before being sent out from the factories? I have written to our local M.O.H. on this subject; but it may serve a useful purpose if you would give me the space to bring it to the notice of a larger public.

Our Dumb Friends League has a branch in our street, and I would expressly exonerate both the dogs and their keeper from all blame.—I am, etc.,

London, S.W.3.

A. R. EATES.

Ex-Service Practitioners Committee

SIR,—In answer to the letters of Wing-Commander H. M. Stanley Turner and for the information of those medical men who are not aware of the fact, it should be known that at the meeting of Council held on June 5, 1946, it was decided to set up a special committee, now known as the Ex-Service Practitioners Committee. This Committee is composed of members appointed by the Council and after its first meeting decided to co-opt a number of recently demobilized practitioners.

The Committee has had under consideration the difficulties with which ex-Service practitioners are faced on their return to civil life and a number of recommendations have already been made to the Ministry of Health, particularly with regard to the returning specialists. A short statement on the recommendations made and the Ministry's comments will be published in the *Journal* at an early date.—I am, etc.;

P. MARTIN BRODIE,

Edinburgh.

Chairman, Ex-Service Practitioners Committee.

Medico-Legal

EXPERIMENT ON CATS: APPEAL AGAINST FINES AT OXFORD

On June 25 Prof. E. G. T. Liddell, M.D., F.R.S., who holds the Waynflete Chair of Physiology in the University of Oxford, was summoned before the Oxford Magistrates' Court on a charge of causing unnecessary suffering to a number of cats by omitting to give them proper care and attention. He was fined £25 and ordered to pay 10 guineas costs, and Mrs. G. K. Scragg, keeper of the animal house, was fined £5 on a similar summons. The prosecution was instituted by the R.S.P.C.A. Prof. Liddell said he was conducting a group experiment on distemper in cats with the drug sulphamezathine. Prof. Harold Burrow, who holds the Chair of Medicine at the Royal Veterinary College, and Prof. A. D. Gardner, who holds the Chair of Bacteriology at Oxford, gave evidence to the effect the cats could not have been caused serious pain.

Notice of appeal was given and the case came before the court (Mr. John Foster, M.P.) at Oxford City Quarter Sessions on Oct. 7, 8, and 9. Mr. A. J. Long, K.C., for the appellants, said that there was no neglect on the part of Prof. Liddell bringing about suffering to the animals. He was carrying out a *bona fide* experiment on the group of cats to discover the effectiveness of treatment by sulphamezathine during an outbreak of distemper. Asked by the Recorder how he would describe the scientific object of the experiment, Prof. Liddell replied: the alleviation rather than the cure of cats' distemper. In the result the Recorder said he would allow the appeal of Mrs. Scragg, but he would dismiss the appeal by Prof. Liddell. None of the allegations was proved against Prof. Liddell except that of overcrowding, and therefore he would reduce the fine of £25 imposed by the City Magistrates to £5. The Recorder added that Prof. Liddell made an error of judgment in putting too many cats in a compound while they had distemper, but he performed no cruel experiment.

Obituary

Lieut.-Col. R. J. C. THOMPSON, C.M.G., D.S.O., M.D., M.R.C.P.

St. Thomas's men in all parts of the world, and those who served with or under him in the R.A.M.C., will regret to learn of the death of Lieut.-Col. R. J. C. Thompson on Oct. 2. It was only a short time since he retired from the post of Secretary of St. Thomas's Hospital Medical School.

Richard James Campbell Thompson, son of Richard Phillips Thompson of Stamford, Lincs., was born on Aug. 1, 1880, and was educated at Marlborough and St. Thomas's Hospital, qualifying in 1904 and serving as house-surgeon there before he joined the R.A.M.C. From 1910 to 1913 he was seconded to the Egyptian Army for work with the Sudan Sleeping Sickness Commission. He served throughout the 1914-18 war, was mentioned in dispatches, received the D.S.O. and was made C.M.G. He commanded No. 36 C.C.S. during its time of greatest activity on the Somme and was later in command of No. 14 General Hospital at Wimereux. Soon after the end of the war he took the M.R.C.P. (Lond.) and the M.D. of Durham University, and worked as physician and surgeon to the Chelsea Royal Hospital. He retired from the R.A.M.C. in 1922. He followed private practice at Bordighera, and he returned to England to take up the congenial post at St. Thomas's Medical School which brought him into touch with all members of the staff and with generations of students. He married a French lady in 1916; their only child was killed on active service with the R.A.F.V.R. in 1940.

G. F. P. writes: The account of the career of Dr. G. DOUGLAS GRAY in the *Journal* of Sept. 28 revived memories of an episode in the history of plague in which he took part. The International Conference held at Mukden in 1911 to study the origin and course of the epidemic of pneumonic plague which caused nearly 50,000 deaths during the winter of 1910-11 in Manchuria and Northern China was attended by well-known authorities for example, R. P. Strong, Kitasato, Zabolotny, Martini, and Wu Lien Teh; Gray was a worthy representative of Britain. His wide knowledge of the local circumstances that were likely to influence the spread of the epidemic and his sound advice upon methods of prevention proved valuable in the discussions. Moreover, before the Conference was summoned, he co-operated with his Chinese colleagues in planning measures for combating the outbreak. He was obviously a man who had an impelling desire to prevent and relieve human suffering. A robust feeling of patriotism, though he never paraded it, animated and upheld him in all his undertakings. In the social hours of the Conference his pleasant humour, expressed with a trace of stammer and with a twinkle in his eye, made him a most attractive companion. I count myself fortunate in having been associated at that time in China with Dr. Dugald Christie, C.M.G., of Mukden, who also was a member of the Conference. Dr. Douglas Gray, of the British Legation in Peking, and Dr. G. E. Morrison, the eminent correspondent of the *Times*, all of whom were possessed by a love of China which was linked to an ardent love of their own country. Dr. Gray was the last survivor of this distinguished group.

The Minister of Health, Mr. Aneurin Bevan, speaking at the prizegiving ceremony of the Royal Dental Hospital, London, said: "The health of the nation has been improving steadily all along the line—except for its teeth. The condition of the teeth of the people of this country is deplorable. Partly this is due to lack of facilities for dental treatment, but the main reason is that people do not yet realize how important is the influence of the teeth on the general health. At present only a small proportion of the population, perhaps one in ten, seeks regular dental treatment. As Minister of Health, I am bound to be seriously concerned about the other nine. When the National Health Service comes into operation, no one will be unable to obtain dental treatment through lack of means. Unfortunately the manpower situation in dentistry is very seriously short. Most dentists are over 45 years of age, and we need an increased entry of students up to 900 a year if the *Dentist Register* is to be kept at its present level. The premises of dental schools must be extended and the teaching staff increased. Dental surgery is one of the most important branches of preventive medicine."

Medical Notes in Parliament

HEALTH SERVICE BILL

SECOND READING IN THE HOUSE OF LORDS

The debate in the House of Lords which the Lord Chancellor opened on Oct. 8 (*Journal*, Oct. 12, p. 558) was continued by Lord MORAN.

On Oct. 9 the National Health Service Bill was read a second time without a Division and was committed to a committee of the whole House.

Lord MORAN said that everyone was convinced that a drastic reorganization of the hospital service was necessary. One-third of the 93,000 beds in the 1,059 voluntary hospitals in England and Wales were in institutions which had fewer than 100 beds—institutions hopelessly handicapped by their size when they attempted to act as general hospitals—and more than one-third of the 78,000 general beds in municipal hospitals were in public assistance institutions.

Reorganization meant a considerable expenditure of public funds and must entail some measure of public control. Control could only be exercised by the Minister or by the local authorities, and faced by a choice between these alternatives the profession preferred the control of the Minister. For a decade every professional discussion of the hospital service had been dominated by the dread that the hospitals would come under the control of the local authorities. It was the removal of that menace from the profession which had reconciled so many to the passing of the voluntary system and which had done more than anything else to make so many prefer the hospital provisions of the present Minister of Health to those of his predecessor.

A University Service

It was important that the hospital service should be a university service. That was the original conception underlying the establishment of the regions. The regions were originally suggested to bring in the universities. During the war all kinds of specialists were sent by the teaching hospitals into the important hospitals in the region. They attended these hospitals regularly, and they raised their standard almost to university standard. When they were called back at the end of the war there was a sharp fall in the efficiency of hospitals at the periphery. The university service could bring about a redistribution of specialists without duress.

The powers of the Regional Boards were vaguely defined in the Bill. If the inspectors worked independently of the Regional Board the Regional Board would lose authority. There was no guarantee that the Ministry of Health would not interfere in clinical matters. That was not a fictitious phantasy. It actually happened under the emergency medical service during the war.

Doctors feared that they would lose their independence. If that happened the profession would indeed have received a mortal blow. Whatever happened to the health services, however effective the reformation of it, it would avail nothing if the general conditions under which doctors worked did not bring contentment and happiness to them. In the innumerable discussions which the Bill had provoked the effect of the Bill on entry into the profession had hardly been mentioned. It was because the Minister treated the teaching hospitals so sympathetically, because he refused to blunt the growing edge of medicine, that, in the first instance, many doctors examined the provisions of the Bill with sympathy. But those who worked in the academic world in medicine were greatly perturbed at the present time about the powers and composition of the boards that would govern the teaching hospitals.

The well-being of the profession depended upon attracting the exceptional man. The fame of the voluntary hospitals had gone all over the world for one reason and for one reason only—namely, that the great advances of knowledge, which had been of incalculable benefit to the whole world, had come from workers within their walls. The physician at last had been armed, and in consequence there was an almost embarrassing rush to become a physician. At the present time the men of promise were entering for the examination for admission to the Royal College of Physicians at the rate of 1,400 candidates a year.

Spens Committee for Consultants

Lord Moran continued: "I gave notice to the noble Lord who introduced this debate that I should ask the Government to appoint a Committee on the lines of the Spens Committee, with laymen on that Committee, to go into the remuneration

of consultants. I am glad to hear the Government consider such a proposal worth considering and that they will do it."

In the United States the public had been educated to believe that if a man's name was not "in the book" he was not a specialist. At the present time anybody could specialize in England without training, without special qualifications, without anything but assurance. The time was coming when we should have a list of consultants as in America—he hoped it would not come yet, because the general practitioner would then be cut off from the mild amount of specialization he at present undertook. The general practitioner must be brought into the work of the hospitals.

Medical Liberty

He was gravely disturbed by the general fears expressed by practitioners as to the future. They were against this abolition of the selling and buying of practices. They were against what they called a measure of direction, and they were against the basic salary; but these "againsts" all came down to one fear—the fear that there would be a whole-time medical service which would interfere with their liberty. "Will this whole-time service necessarily be good for the profession or the public? I do not think anyone knows the precise answer, but one thing I am certain of: unless there is an adequate incentive or incentives to keep men on their toes and to keep them keen throughout their working days, then a whole-time service would be an incalculable disaster. At the present time I am quite certain that the average doctor lives for his work. What we have got to ask is: will it be true in ten years' time? If I knew the answer to that question I should be able to tell you if the misgivings of the general practitioners are or are not true."

An unfortunate dispute at the eleventh hour had arisen between the Ministry of Health and the panel practitioners. Lord Moran was convinced that the claims of the panel practitioners were fair and just, but the dispute was not about terms but about procedure. The Minister wished to go into the remuneration of panel practitioners at the same time as the remuneration of men in this future service. The panel practitioners felt they had not a mandate for this discussion. He was perfectly certain that the Minister would meet their claims. It would be an absolute disaster if we began this service with a considerable section of practitioners disgruntled—men who felt that they had had a raw deal.

Lord Moran concluded by saying: "This is a measure designed for the betterment of the people in health and in happiness. It is not the product of one party but of parties over a number of years, and I believe that when it becomes law, in spite of all the differences there have been, the whole medical profession will unite to try to make it work."

Lord INMAN, who said he had been associated with hospital work for nearly thirty years, said that years ago hospitals were maintained entirely from voluntary sources, but such was not the case to-day. All sorts of weird appeals were organized to intrigue the public into giving. It was definitely wrong to depend on "stunt" appeals. He yielded to none his admiration of the work of the voluntary hospitals, and to those who said that they were to be killed under the Bill he would reply that the self-sacrificing spirit which had characterized their work would be allowed to continue. In these modern times the heavy cost of curative and preventive treatment and the building and equipment of hospitals meant legitimate financial demands which it was not within the power of voluntary effort to satisfy. The new Bill would continue and expand the work of the hospitals, building on their tradition and experience, to form a worthy edifice of which this country would be proud in years to come.

Evolution—Not Revolution

Lord HORDER said that for the last twenty years doctors had done their utmost to persuade the powers-that-be "to get a move on." But the doctors had hoped that it would be through the more natural process of evolution, rather than through the present method of revolution, that the Government would help them.

"More than once I have allowed that this Bill enhances one very desirable thing—that is, the availability of medicine to the citizen. But, as has been said by one of the speakers here this afternoon, we may pay too much for that advantage if it is gained in a way which does not take into account the possible sacrifices that are entailed. And you cannot stereotype medicine without a great deal of sacrifice. We believe that this Bill does risk stereotyping medicine, and whether we look at medicine from the point of view of the hospital services or from the point of view of the work of the individual doctor it must be a great loss to society if by the operation of this Bill medicine is stereotyped."

The ideal to be aimed at in framing a medical service policy for the nation was not this terrific centralization of power in

one man but a maximum of central direction and a minimum of central control. Closer contact with the medical profession during the framing of the Bill would have safeguarded the Minister, and his successors, under the Bill from the danger of over-centralization. When the Minister was criticized in another place for not discussing his proposals with organizations and bodies representing those who would be responsible for carrying them out he denied the imputation and spoke of consultations—that was his word—which were very wide.

Lord Horder continued: "The Minister uses the word 'consultation' in a very different sense from the one which we usually attach to that word. I was myself present at two of these so-called consultations. The form they took was as follows: The Minister told us what he proposed to do; he answered a few of our questions, and the conference concluded with his telling us that what he had said was to be kept secret. To this unilateral pledge all of us loyally adhered, to find ourselves quite soon tactically handicapped. We were hamstrung. The word 'consultation' was a euphemism for the most blatant form of *ipse dixit*-ism. It seemed to me at the time—and it still seems to me—a very unfortunate and a very unhelpful handling of this vital situation."

Remuneration of Doctors

They had been told that the remuneration of doctors would be in part by basic salary and in part by capitation fees, and that the capitation fees would scale down as the number of the doctor's patients under the national service increased. Now, by regulation, the percentage of remuneration by capitation fees might be reduced; it might ultimately disappear, at which point the doctor became a whole-time salaried Civil Servant. Was this good for medicine or for the community?

"I see no escape from this unthinkable state of affairs except through the medium of a black-market in doctoring, and my mind boggles at the thought of its probable immensity. And yet could we be other than sympathetic if we believe that it is the only salvation for the patient? The Minister tells us it is not possible to insert the terms of remuneration in the Bill. But it should be possible so to amend an existing clause that the method of payment is stated, and this method should be the capitation method unless, in the opinion of the Executive Council in whose area the services are rendered, a different basis is considered necessary."

The prohibition placed upon the buying and selling of a doctor's goodwill for his practice, the power of negative direction of doctors, and the refusal to allow a doctor charged with some offence under the Bill the right of appeal to the High Court were surely matters that required amendment. They seemed to be gross infringements of personal liberty.

Doctors thought that the Standing Advisory Committee of the Central Health Services Council should be appointed by, and take their references from, the Council, and that they should report through the Council to the Minister. The constitution of the local Executive Council should be safeguarded in respect of its medical, dental, and pharmaceutical representation. At present the Minister had power to vary the proportion of medical and lay representation.

Hospital Management Committees

In order to ensure more autonomy for hospitals and, therefore, in order to retain local interest in them, hospital management committees, acting for a group of hospitals, should appoint a house committee in each hospital of the group, subject to the hospital management committee and the Regional Management Committee.

It should be one of the functions of the hospital management committee or of the house committee to set up a medical staff committee, and such committee should have the right to nominate a reasonable number of its members to be members of the hospital management committee or house committee. On the question of medical education, the Bill needed amending, for at present it made no provision for the laying upon the boards of governors of teaching hospitals any duties in respect of furthering medical education and research.

There had been moments of impatience in which the Minister had forgotten that if he did not take the doctors, the hospital administrators, the dentists, the nurses, and the health workers with him the Bill could not succeed in its great purpose. Sometimes he remembered this, as he did only a few days ago when he said: "Now what we hope is to get the co-operation of the great medical profession and of all health workers in the country, because without that co-operation this scheme is bound to fail. The House of Commons only passes Bills; it is the men and women outside who can make them living realities." This was surely the beginning of wisdom. The Minister had courage, enthusiasm, a nimble mind, and a conscientious belief that these proposals were in the best interests of the community. "I think that the Minister

will go far, but in what direction I am not able to say. I think the prognosis in that respect extremely difficult."

Finally, Lord Horder said it was quite obvious that we were about to embark upon a great experiment in the national medical services. It was the doctor's duty to do his utmost to make the experiment succeed. But there was for the doctor an over-riding duty—his duty to his patients. If he could fulfil this paramount duty through these means he would, but it could not be for the patient to decide how long a sacrifice of efficiency should continue.

The Local Authorities

When the debate was resumed on Oct. 9 Lord LISTON replied to some of the points made on the previous day. said Lord Munster had complained that the Bill weakened spirit of local patriotism and of voluntary service by transferring the hospital service from the local authorities to the State. But public-spirited persons who had served on local authorities would not be deterred by the change. In the past many counties and county boroughs had done little to develop hospital service. The large local authorities which ran general hospitals would be no worse off than they were in 1928. Under the Bill these larger local authorities acquire a range of obligations and permissive powers in health services which they had never hitherto had to discharge. The Bill not propose that the Ministry of Health should run the hospitals. Clause 11 said that the Minister must—not may—delegate his powers to regional hospital boards and from them to hospital management committees, or in the case of teaching hospitals to boards of governors. Each hospital committee would be free to decide how its money should be spent within the limits of an annual budget. Hospital committees—boards of governors would be as independent in their day-day arrangements for running the hospitals as the committees that ran them now.

In delimiting the regions to be administered by regional boards the Minister must consult the interested parties before making up his mind. He would then define the regions by regulations, and if a noble lord disapproved of one of the regulations he could move its rejection in the House. Was not, and never had been, the policy of the Government to institute a full-time salaried medical service which would withdraw the whole health scheme from the outset. The Government desired a system of remuneration based partly on capitation fees and partly upon a basic salary. At the same time deprecated the suggestion that full-time employment of doctors in public service led to inefficiency or neglect of patients. The professional standards of medical officers of health or of other doctors employed in hospitals run by local authorities, as a class of doctors employed in the Armed Forces, were as high as those of doctors in private practice. Hospital endowments in memory of an individual would still be used for the benefit of the sick and when an allocation was made from the hospital endowment fund to any particular hospital the wishes of donors would not be forgotten.

Health centres under the Bill would be experimental, and in view of other demands on the building industry it was impossible to wait until every health centre could be newly built.

Domestic Affairs of Hospitals

Lord Moran had asked whether the Ministry or the regional board would investigate hospital complaints and engage or dismiss nursing staff. Both these powers would be delegated to the regions, and there was no real danger of Whitehall interfering in the domestic affairs of hospitals. Lord Moran had mentioned the difference of opinion between the Ministry and the panel practitioners. A meeting between Mr. Bevan and the representatives of the profession would take place on Oct. 10.

The spirit of voluntary service must be retained in the hospitals. Lord Horder had said his ideal for the medical service was the maximum of central direction and the minimum of central control. That was what the Government aimed at under the Bill. Lord Horder's fear of a dead level of mediocrity in the medical profession would prove to be groundless. The service would continue to be a graduated scale in the salaries in the hospital service and progressive remunerations for general practitioners. The good man would have every incentive to get on in medicine. The Bill as it emerged from Parliament would only be the skeleton of a national health service. The service would need the genuine good will and co-operation of the engaged in medicine, and also of public authorities and voluntary agencies. No less essential would be an intelligent and responsive attitude to its own health in the mass of the population.

There had already been ample opportunity for consultation and every view of any importance had been given prolonged

The Successful Treatment of FIBROSITIS and certain cases of RHEUMATISM with NOVUTOX

A mass of evidence has accumulated to show that the treatment of Fibrositis and certain cases of Rheumatism with Novutox injections provides not only complete restoration of function with immediate relief from pain, but also, in many cases, early recovery.

Interested members of the medical profession are invited to write for a copy of a Thesis on "THE INJECTION TREATMENT OF FIBROSITIS—with special reference to: Lumbago, Muscular Rheumatism (Acute and Chronic), Muscular Pain (of Traumatic Origin)."

NOVUTOX is available in:

2-oz. and 20-oz. Bottles: 1%, 1% and 2% Solutions
Boxes of 12 x 2 c.c., Ampoules: 1% and 2% Solutions.

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreitoloxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

consideration. When the time came for action it was to be hoped that differences would be forgotten and that the ranks of medicine would be closed to implement the plan. Such an attitude of mind was a patriotic duty. The debate so far had shown a foundation of agreement about the main principles on which the Bill was based. It was not the product of any single party or Government.

The advocacy of a wider and more comprehensive medical service had become more prominent in the B.M.A. during the war, and many doctors then began to press for drastic improvements in what they deemed to be the present inadequate system. The imagination of the public was then gripped by the social security proposals in the Beveridge report. Thereafter the ideas in the Bill had come from varied sources. If the Bill moved in the direction of State medicine it combined freedom for doctors and patients with over-all planning, private and public practice, and unpaid voluntary service with salaried contractual obligations. It was as far from the State system of medicine practised in Russia as it was from the commercial medicine favoured by the United States of America.

Criticism of Bill

Lord LYLE said the Bill was another step on the slippery road leading to nationalization. The promise by Mr. Lloyd George of "ninepence for fourpence" was a small exaggeration compared with the promise of a free health service which in fact was going to cost approximately £150,000,000 a year. In dealing with the position of the doctors, their patients, and the voluntary hospitals this was a thoroughly bad Bill. The outlook for patients under the Bill was gloomy. They would have no satisfactory way of airing their complaints. There would have been no loss had Mr. Bevan allowed existing endowments of hospitals to be preserved so that the wishes of the departed donors could have been respected.

Economic Barrier Removed

Lord BEVERIDGE said he gave whole-hearted support to the Bill in practically all its main features, though it was not intended to do everything that was wanted to promote the health of the people of this country. Health depended on housing, nutrition, sanitation, and so on. The Bill removed completely the economic barrier between sick persons and the best possible treatment. It set up for the first time a true Minister of Health. He hoped that meant that the Ministry was going to be a continual irritant to authorities who were not getting on sufficiently with housing, sanitation, and nutrition.

He did not think that the question of private practice would be very important. He could not imagine any large part of the people continuing to pay for such service when they were entitled to get as good a one without paying for it at all. The regional hospital boards were an improvement on the joint authorities. He was not sure that the executive councils would sufficiently represent the ordinary citizen. At one time the opinion of doctors was in favour of getting health centres. He hoped this was still so. He asked whether there was any means of compelling a local authority to set up a health centre.

His experience as a university teacher was that it was possible to receive the whole of one's income as a salary while retaining freedom, initiative, and a sense of being in the service of the people with whom one dealt. Through the Grants Committee the universities received public funds without public control. He hoped a system of that sort could be applied to the medical services, and above all to the teaching hospitals. The main difference between university teaching and the medical profession was that the medical profession had to work harder at less regular hours, and its job was not so pleasant; it should therefore be paid better than university teaching. The plan of a relatively small salary with capitation fees seemed a good device. The doctor ought to be able to choose to work harder to get more income.

He hoped the medical profession would take from the university teaching profession the practice of refresher courses. Under the new system a doctor would have the chance of six months or a year at a time to rub up his subject. The spirit in which the Bill would be administered could be judged by the spirit in which the Government would approach the amendment which would be moved in the House of Lords. In some matters the Bill was too rigid.

Subscriptions to Hospitals

Lord LUKE said the battle for nationalization had been won and lost in the House of Commons. He thought that the greater tidiness which might result under the present scheme would be at the cost of greater efficiency and more personal service. The Hospital Endowments Fund created by the Government was a big pill to swallow. At the moment people hesitated in making subscriptions, and that was bound

to continue in view of Mr. Bevan's assurance that hospitals in financial difficulties might appeal to him for assistance. Lord LUKE understood that they would not appeal in vain. It was difficult to balance this with the maintenance of an incentive to people to give money to hospitals. How could Mr. Bevan expect to get large subscriptions in the future if he continued to insult the large contributors? He hoped that a formula could be evolved for the interim period which would prevent people's generous habits being broken.

In regard to the non-teaching hospitals, he asked whether it was possible for management committees to manage their hospitals efficiently if they did not have control of the staff. That control had been vested in the regional boards, and there was no provision in the Bill to give effect to the assurance of the Government that there would be no interference by the regional boards with the management committees. The net annual expenditure of the new hospital service would be about £95,000,000. Did that figure include the additional beds which were needed to provide adequate accommodation? He understood these additional beds would number about 90,000. For these the cost would be £135,000,000. He estimated that the country needed 7.6 beds per 1,000 of the population. This on the 1941 census was equivalent to 315,000 beds. The existing provision was 225,000 beds. When would the extra beds be available and how were the hospitals to arrange staff for the additional accommodation? The public had been led to expect something far and away better than the present system. He would do all he could to ensure co-operation, to forget past differences, and to improve what was good.

Lord DONOUGHMORE said it was obvious that voluntary contributors could not face the enormous increase that would be necessary in financing the hospitals of the country. The voluntary hospital had not been called so solely because it was supported by voluntary contributions. On its board men representing all the professions gave their services to the sick for nothing. Unless the medical profession found it possible to support this Bill heart and soul it was bound to fail. The medical profession was altering every day, and he hoped it would not have too much direction in detailed matters of administration. He hoped they would soon be told how many regions there were going to be and what were their functions. In London he had been concerned this summer with negotiations for co-operation between four large hospitals. These hospitals would like to co-operate but did not know which regions they were going to be in.

Dismay of Local Authorities

Lord ADDINGTON said people must come before plans and administrative machinery. Love, care, and consideration could not be exercised if there was friction between the doctors and the Government or between the doctors and the patients, nor would the aims of the Bill be fulfilled if the doctor was not free to follow his own conscience. He hoped the House of Lords would be able to make considerable improvements in the scheme. Some of these were desired by the borough councils of England for which he spoke. Non-county boroughs viewed with dismay the loss of their maternity, child-welfare, and other health services, and so did the county councils the transfer of their hospitals to the Minister. The people had come to look to these local authorities for their needs in public health. The borough councils would like provision to be made to enable a county council to delegate some or all of its public health functions to its non-county boroughs. Local health authorities should be able to nominate their representatives upon the regional hospital boards, management committees, and boards of governors of the teaching hospitals, and should have representation upon the Central Council.

With regard to the voluntary hospitals, he believed those who lived in these areas would find it detrimental always to be treated thirty or fifty miles away. They would prefer to be treated in the small hospitals in their own towns and by their own doctors. They also wanted to be visited by their families and friends. This was particularly the case with chronic invalids. Some of these chronic cases might be given a few of the beds in small hospitals in their own towns. These hospitals should be continued, and there should be a house committee for each of them. In the last week of September the B.M.A. had inaugurated a World Medical Association, with representatives of 31 different nations. The aim was to assist all the peoples of the world to a higher level of health. That had been welcomed by Mr. Bevan, who pointed out that there was in medicine a concern for the individual and that the primary concern of doctors was that the thing necessary should be done. If the Government showed greater care for the health of the people than for political advantage or for preconceived plans the doctors would show they cared much more for the health of the common folk than for financial advantage and some of their professional traditions.

Direction of Doctors

Lord LLEWELLIN said he approached the Bill solely from the point of view of the patient. From the patients' point of view the time had come for a better health service. In his view the Bill did not in the right and best possible way take steps to improve the hospital services and the health services generally. The majority of doctors disliked being controlled. There was no need whatever to buy the doctors out of their practices. The problem of attracting doctors to the under-doctored parts of the country was comparatively small, and it could have been met on the lines of the scheme for the Highlands and Islands of Scotland, which by special inducement secured doctors to serve in those parts. That could have been worked for a far less cost. The new entrants who looked round for a safe job with a regular salary were not the men who rose to the top of their profession. He fancied that in the main the new men who would come into the State medical service would not be the active, progressive men who should be engaged in a great science such as medicine. As a patient, he said: "When we are short of doctors do not let us do anything to drive some of them away. Let us do everything to get the best recruits into the medical profession." Under the Bill the Minister could be questioned in either House of Parliament on anything which happened in any hospital. That was a frightfully hampering thing. If mistakes were made in the hospital an instruction would go out to all regional boards and hospitals that nobody was to do things in that way in the future. Staffs would be tied up by quantities of forms to fill in and quantities of instructions to read. Those for whom he spoke were not going to divide against the second reading of the Bill.

Closure of Debate

The LORD CHANCELLOR closed the debate. Many of the points made were committee points, and he promised that the amendments moved would receive careful consideration, though great care had been taken in preparing the Bill and Mr. Bevan had made considerable concessions. The House would not suppose that the Government assented to any particular amendment. The Labour Party had no doctrine against charity, but they objected to services of essential importance being left to the mercy of charity instead of being provided out of public funds. Essential services to-day were so much more costly than thirty years ago that the State had to come in.

He was sorry some statements had been made which might lead doctors to suppose that the Government was going to nationalize medicine or that the doctors were going to be enslaved. If the Government were to propose a scheme whereby the doctors would become salaried Civil Servants they would not come in. The Government had no such intention. The fear of interference with the doctor should not be encouraged by responsible members of the House of Lords. Mr. Bevan only wished to pay a minor part of the doctors' remuneration in the form of salary. Payment of salaries to university professors and judges did not enslave them. If it was enslaving doctors to say that the new entrants to the Service after the appointed day must get the consent of the Medical Practitioners Committee when taking up public practice, that was precisely the proposal of the Coalition Government. When there was a partnership of three doctors of whom one died and the others wished to get a new man, then the most relevant fact considered by the panel would be: "Here is the man the other two want." In 99 cases out of 100 the man who was wanted would get his way.

On the selling of public practices he thought that in a country practice where patients had no choice of doctors a man indulging in public practice who sold it was virtually selling his patients. If two men came after the practice one of whom was less suitable but was prepared to pay a larger sum, what was the reaction of the vendor? For that reason the Government thought that the selling of a practice by a man who was getting his remuneration in part from public funds was no longer right. He underlined what had been said about the necessity for decentralization. This scheme would fail unless the Minister decentralized on the largest possible scale. The Government believed that the transfer of functions from minor to major local authorities was essential, because in that way alone could the present confusion be removed. The treatment of endowments had its precedent in an Act passed by the last Government, whereby, by Order in Council, endowments given to schools for particular purposes could be taken away and used for different purposes without the consent of the trustees. Under the Bill endowments, after passing to the Minister, had to be reallocated by regulation. The Minister would consider whether a particular bequest was for some local purpose. He renewed his assurance that in Committee the Government would look carefully at all amendments and see whether any of them could be accepted as improving the Bill.

The Bill was then read a second time.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a Congregation on Oct. 1 Mr. H. Thirkill, Master of Clare College, resigned office as Vice-Chancellor, and was re-elected for a further year. In his address to the Senate he made the following reference to the expansion of medical education which the University has had under consideration for some time:

"In general, it was considered that the first step in this expansion should be the establishment of a School of Postgraduate Teaching and Clinical Research composed of Departments in special branches of medicine, which could be in close touch with the established University Departments of Science. A beginning has been made with the creation of a Department of Experimental Medicine and a Department of Radiotherapeutics. In these and other Departments which have been contemplated, and are likely to be established later there will be opportunities for postgraduate training as well as unrivalled facilities for research. The implementation of this plan has called for the closest co-operation with Addenbrooke's Hospital. It is expected that an important step towards the fusion of the interests common to the University and to Addenbrooke's Hospital will be taken during the year by the University Departments of Pathology and Biochemistry becoming responsible for the pathological and biochemical services of the hospital. This should be of mutual benefit. For the hospital, there will be available the resources and expert knowledge to be found in a University department. For the University, there will be the large field of study and research provided by the evidence accessible at the hospital, while the other specialist University Departments, already created or contemplated will have a complete University organization in the basic sciences of pathology and biochemistry to which problems can be referred for advice, assistance, or solution. The whole trend of this policy is in keeping with the general recommendations of the Report of the Interdepartmental Committee on Medical Schools, which is designed to make the University the focus of medical education and research for what will eventually be the East Anglian Region. It is felt, too, that the special Departments will have an attraction for postgraduate students and research workers far beyond the local region, extending to the Dominions and Colonies. At the same time, the need for educating general practitioners in modern medicine has been appreciated. The honorary staff of Addenbrooke's Hospital have, during the past year, given a number of postgraduate courses in general medicine to returned ex-Service medical men. The experience gained from these courses will be of great value in framing suitable courses of instruction for general practitioners in civil practice. The question of the organization of the School of Postgraduate Teaching and Clinical Research is under active consideration by the University and hospital authorities concerned and a report will shortly be presented to the University."

During the months of August and September titles of the degrees of M.B., B.Chir. were conferred by diploma on the following members of Girton or Newnham Colleges: R. S. J. Baker, Mr. H. F. Barnes, K. A. C. Bowen, J. E. G. Brieger, F. M. Fountain, J. F. Grant, Mrs. M. C. Hare, M. Hobson, P. A. Howard, E. C. Howe, G. M. Hunt, H. M. J. Lawn, B. M. Leach, Mrs. J. Raymond, A. M. Sibly.

G. R. E. Naylor, M.B., B.Chir., demonstrator in pathology, has been elected into an official Fellowship at Gonville and Caius College.

The names of candidates for the M.Chir. examination should be sent to the Registry by Dec. 31. The examination begins on Feb. 18.

UNIVERSITY OF LONDON

Ian Aird, Ch.M., F.R.C.S., has been appointed to the University Chair of Surgery tenable at the British Postgraduate Medical School. Miss Dorothy Russell, M.D., Sc.D., to the University Chair of Morbid Anatomy, and Clifford Wilson, D.M., to the University Chair of Medicine, both tenable at the London Hospital Medical College. J. L. D'Silva, D.Sc., M.B., has been appointed to the University Readership in Physiology tenable at St. Bartholomew's Hospital Medical College, and J. M. Robson, M.D., D.Sc., to the University Readership in Pharmacology tenable at Guy's Hospital Medical School.

SOCIETY OF APOTHECARIES OF LONDON

The Gillson Scholarship in Pathology of the annual value of £10 is open to candidates under 35 years of age who are licentiates or freemen of the Society, or become so within six months. Regulation may be obtained from the Registrar, Society of Apothecaries, Blackfriars Lane, E.C.4.

Welfare work in Greece, a children's hospital in Yugoslavia, and day nurseries in Great Britain are among the subjects discussed in the September number of *The World's Children* (20, Gordon Square, London, W.C.1, price 6d.).

No. 39

INFECTIOUS DISEASES AND VITAL STATISTICS

Print below a summary of Infectious Diseases and Vital statistics in the British Isles during the week ended Sept. 28.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) be 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Outbreak of Ringworm

The county medical officer of health for West Lothian states that the outbreak of ringworm of the scalp in the Bathgate area involves 160-170 cases. A clinic has been improvised at one of the Bathgate schools and the cases, most of which arose during the summer vacation, will be dealt with by x-ray epilation. Routine measures of isolation and instruction about prevention are already tending to check the outbreak.

Discussion of Table

In England and Wales a decline was reported in the incidence of whooping-cough 159, while an increase was recorded for measles 253, scarlet fever 148, and diphtheria 45.

The notifications of whooping-cough have decreased for six consecutive weeks. A small decrease was reported from most regions and the largest local falls were Lancashire 37 and London 19.

The only variations of note in the incidence of scarlet fever were increases in Yorkshire West Riding 35 and Durham 20. A rise was recorded in the notifications of measles following a continuous decline for the last eleven weeks. The incidence tended to increase in most regions with the exception of London and the South-East, where a fall of 74 occurred; the largest rises were Devonshire 110, Northumberland 70, and Yorkshire West Riding 44.

Diphtheria was generally slightly more prevalent during the week. The largest rises were Lancashire 23 and Warwickshire 11. The total number of cases of dysentery in the country was unchanged; the largest local variation was an increase of 15 in Middlesex (Southall M.B. 10).

In Scotland a rise in incidence was reported for dysentery 18, measles 18, and scarlet fever 10, while a fall of 27 was recorded for whooping-cough. The largest local increase in cases of dysentery was at Edinburgh, where the notifications increased from 3 to 14.

In Eire a rise of 20 in the cases of scarlet fever was due to a general rise in incidence. The increase in whooping-cough was mainly due to the experience of Dublin C.B., where the cases rose from 15 to 32. The incidence of diarrhoea and enteritis remained practically unchanged; 49 of the cases were notified from Dublin C.B.

In Northern Ireland only small changes in the totals of infectious diseases were reported.

Quarterly Returns for England and Wales

The Registrar-General's returns for the June quarter record a birth rate of 19.2 per 1,000, the highest rate in any quarter since that of June, 1925. The infant mortality was 41 per 1,000 live births, being 9 below the average of the ten preceding second quarters. The death rate was 10.7 per 1,000, which was 0.3 above the rate for June, 1945, but 0.9 below the average death rate for the five preceding June quarters.

Infectious Diseases in the Third Quarter

Notifications of infectious diseases during the September quarter of this year showed considerable changes in the general trend of diphtheria, dysentery, and the enteric fevers.

The notifications of diphtheria have been at the lowest level recorded. For each of the thirteen weeks of the third quarter the total has been below the 346 cases which was the lowest level reached in 1945. Cases of diphtheria in this quarter are only two-thirds of the number in the corresponding period in 1945 and approximately a quarter of the number occurring ten years ago. Diphtheria notifications in the third quarters of the past ten years, 1937-46, were: 13,395; 13,639; 10,632; 11,387; 10,631; 9,517; 7,951; 6,133; 5,437; 3,473.

The incidence of dysentery, which rose continuously throughout the war, has fallen rapidly during the third quarter and the total for the quarter is only 27% of that for the same period of 1945, though still almost twice the pre-war level. The notifications for the third quarters of the ten years 1937-46 were: 532, 430, 464, 613, 1,320, 1,718, 2,501, 3,509, 3,396, 923.

The enteric fevers (typhoid and paratyphoid) reached a high level of incidence during the third quarter. The totals for the September quarter of the ten years 1937-46 were: 603, 401, 636, 1,427, 2,876, 261, 240, 245, 255, 723. The high value in 1941 was due to an outbreak of paratyphoid which originated from cream cakes in a multiple bakery in the Liverpool area. The rise this year was mainly due to typhoid contracted by eating ice-cream in Aberystwyth M.B. The sanitary control of ice-cream is the subject of an annotation at page 584.

The Health of Edinburgh

The report of the medical officer of health for 1945 records a birth rate of 15.4 per 1,000, a decrease of 1.2 on the 1944 rate. Infant mortality was 50 per 1,000 births, the lowest rate ever recorded. The infant mortality rate in Edinburgh has been below the rate for the other three large cities since 1920; the corresponding figures for these cities in 1945 were Glasgow 68, Dundee 57, and Aberdeen 54. The general death rate was 14.4 per 1,000 and was 0.6 below the average for the preceding five years. There were 218 deaths attributed to pulmonary tuberculosis, the lowest death rate from this disease on record, but the number of new or suspected sufferers from this disease was the largest ever dealt with by the Department of Health.

Week Ending October 5

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,079, whooping-cough 1,311, diphtheria 319, measles 1,781, acute pneumonia 411, cerebrospinal fever 32, dysentery 63, acute poliomyelitis 23, paratyphoid 20, typhoid 11.

Medical News

Dr. J. Calvert Spence will deliver the Charles West Lecture on Tuesday, Nov. 19, at 5 p.m., at the Royal College of Physicians of London. Subject: "The Care of Children in Hospital."

The next meeting of the Middlesex County Medical Society will be held at Hillingdon County Hospital, Hillingdon, Middlesex, at 2.30 p.m. to-day (Saturday, Oct. 19).

Dr. G. Roche Lynch will deliver a lecture entitled "Medico-Legal Experiences" before the Hull and District Branch of the Royal Institute of Chemistry at the Guildhall, Hull, on Wednesday, Oct. 23, at 7.30 p.m. At Dr. Roche Lynch's request the secretary cordially invites members of the medical profession to attend this lecture.

At a meeting of the Medico-Legal Society at 26, Portland Place, W., on Thursday, Oct. 24, at 8.15 p.m., a paper will be read by L. Le M. Minty, Ph.D., on Legal Aid to Assisted Persons.

At a meeting of the Medical Society for the Study of Venereal Diseases at 11, Chandos Street, W., on Sat., Oct. 26, at 2.30 p.m. Dr. F. R. Curtis will give an address on Venereal Disease in Occupied Germany.

Dr. Neville Lloyd, M.R.C.P., has been appointed chief medical officer, Ministry of Supply, with effect from Sept. 23, 1946. Dr. Katharine Williams, M.R.C.P., who has held the locum tenens appointment as C.M.O., has now taken up duty as principal medical officer, Atomic Energy Research Establishment, Harwell, to which she was appointed on June 11, 1946.

At a scientific reunion of the Société Internationale de Chirurgie Orthopédique et de Traumatologie held in Brussels on Oct. 3 and 4, Prof. Louis Ombredanne was re-elected as president, and Dr. Jean Delchef as secretary-general of the Society. Prof. Harry Platt and Dr. San Ricart (Barcelona) were elected vice-presidents. Dr. Henry Meyerding, of the Mayo Clinic, was elected as president of the next congress, which will be held in Amsterdam in September, 1948.

The first number of a little weekly periodical, *Science To-day*, is dated Oct. 10, 1946. The editor is Mr. A. W. Haslett, M.A., who until recently was Public Relations Officer of the B.M.A. It is published from 104, Clifton Hill, London, N.W.8, and the subscription rate is 30s. a year.

At the 125th anniversary of the founding of McGill University, Montreal, honorary degrees were conferred on Sir Hector etherington, Principal and Vice-Chancellor of the University of Glasgow, and on Dr. Thomas F. Cotton, F.R.C.P., physician to the National Heart Hospital, London, who graduated at McGill University in 1909.

The Dean of Westminster Hospital Medical School, presenting his report for the year on Oct. 7, referred to the amalgamation with the Infants Hospital, Vincent Square, and with All Saints' Hospital for Genito-urinary Disease. The first professorial chair in the School has been created—that of clinical pathology. A pre-war association with the Army Medical College, Millbank, has been resumed, and postgraduate instruction is being given to a number of officers. London University is to make a grant of £25,000 to the School in the coming year.

The Unionist Committees of the four Scottish Universities have unanimously decided to adopt the Right Hon. Walter Elliot, F.R.C.P., F.R.S., as their candidate in the Parliamentary by-election caused by the resignation of Sir John Boyd Orr. Col. Elliot represented the Kelvingrove Division of Glasgow for 21 years until defeated at the General Election. He was Minister of Agriculture, 1932-6, Secretary for Scotland, 1936-8, and Minister of Health, 1938-40.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to 1 EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publisher, B.M.A. House, Tavistock Square, W.C.1, on receipt of proof. Authors over-seas should indicate on MSS. if reprints are required, as proof are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Heliotherapy in Pulmonary Tuberculosis

Q.—Is heliotherapy harmful or not in pulmonary tuberculosis?

A.—In 1932, Fishberg (*Pulmonary Tuberculosis*, 4th edn. Kimpton, London) remarked that hardly any writer has advanced a sound reason for the use of heliotherapy in pulmonary tuberculosis. Nothing has been recorded since that time which justifies any alteration of this opinion. Gosse and Erwin (*British Medical Journal*, 1934, 2, 15) have shown that the onset or exacerbation of symptoms in cases of pulmonary tuberculosis often follows sunbathing, and there is considerable evidence that heavy exposure to sunlight can produce a focal reaction around an exudative lung lesion. In a recent review of the whole subject, Mayer (*Radiation and Clinical Therapy of Chronic Pulmonary Disease*, Williams and Wilkins, Baltimore, 1944) concludes that there is no clinical evidence to prove the value of light radiation in uncomplicated pulmonary tuberculosis, while there is considerable evidence that it can be harmful.

Malaria Prophylaxis

Q.—Can you recommend a non-toxic prophylactic, other than quinine, against malaria?

A.—Mepacrine 0.1 g. daily by mouth acts as an efficacious suppressive agent against malaria. Most persons find it relatively non-toxic although it has the disadvantage of staining the skin yellowish. Paludrine, a colourless compound, in a dose of 0.1 g. twice weekly, or chloroquine in a single dose of 0.3 g. weekly, appear even superior to mepacrine in their suppressive actions, but they are not yet ordinarily available although it is expected that paludrine will be readily obtainable within a few months.

Premature Baldness

Q.—I have been asked by a mother if I can do anything to prevent her son, now aged 3, from going bald at the age of 1. Her father and two brothers went bald at that age.

A.—It is a little early to condemn a male infant to premature baldness. For the true masculine type of baldness not much can be done; but when, as often happens, this is associated with seborrhoea of the scalp (dandruff) beginning in late adolescence the active treatment of the seborrhoeic component by sulphur pomades or a resorcin lotion, with regular shampooing, usually delays the more complete forms of baldness for many years. The answer, therefore, is the early treatment of any scalp seborrhoea should this be present or develop.

Right and Left Systolic Blood Pressures

Q.—In many cases of hypertension the systolic pressure of the left arm is higher than that of the right arm. Why should this difference be found and which reading is the correct one?

A.—As a rule the blood pressures in the arms are approximately equal and rather lower than the pressures in the legs. It is not uncommon for a disparity to exist between the systolic pressures in the arms. Provided the difference does not exceed

) mm. of mercury it may be disregarded unless there are other reasons for expecting inequality. In subjects free from cardiovascular disease neither side is more likely than the other to give the higher pressure. A reduction in the blood supply to the limb will result in diminution of the pulse and lowering of systolic and diastolic pressures in it. Lesions of the aorta obstructing the mouths of the great vessels, advanced peripheral arterial disease, pressure on the artery from without, and atrophy of a limb are the most likely causes. Whenever there is a difference between the blood pressure measurements in the arms the higher should be taken as more nearly corresponding to the power of the left ventricle (systolic) and to the general peripheral resistance (diastolic).

Penicillin for Chronic Otitis Media

Q.—Would it be advisable to use penicillin in the form of drops in a child with chronic otitis media?

A.—Penicillin could not be expected to have more than a temporary effect at best in a chronic infection of this kind. Penicillin given in drops would not reach the antrum.

Air Travel and Pregnancy

Q.—A seven-months pregnant woman is obliged to travel by air. Is there a risk of premature labour? If so, would progesterone be of prophylactic value?

A.—Unless there is reason to believe that this woman is in some way predisposed to abortion and premature labour the risk of interruption of the pregnancy is probably little greater than if she did not undertake the journey. The widespread belief that travelling in itself increases the incidence of abortion and premature labour appears to be insecurely founded and has not been substantiated by controlled observations. A recent investigation reported by A. W. Diddle (*Amer. J. Obstet. Gynaec.*, 1944, 48, 354) showed that rough travelling did not increase the abortion rate in a series of pregnant women. The real reason for advising a pregnant woman against undertaking long journeys is not that premature labour is more likely but because she might be in difficult circumstances if it did occur.

If a pregnancy is complicated by some condition predisposing to its premature termination the position is probably different. Travelling, or indeed any minor physical or emotional upset, might then be sufficient to precipitate the onset of expulsive uterine contractions. In the case mentioned, if the pregnancy is normal there is little point in administering progesterone, although it could do no harm and might give the patient more confidence.

T.A.B. Inoculation of Infants

Q.—A patient returning to Rhodesia with her daughter, aged five months, is anxious for the infant to be protected with T.A.B. vaccine. Is this necessary?

A.—Typhoid and paratyphoid infections are rarely encountered in young infants. Provided the feeding can be controlled and sterilization ensured it would not appear to be necessary to inoculate this infant.

Silicosis and Bronchitis in "Saw-doctors"

Q.—Is the diagnosis of silicosis likely to be correct in the case of a bronchitic saw-doctor with finger-clubbing and doubtful x-ray findings?

A.—No. Grinding band-saws on a rapidly revolving carborundum (silicon carbide) disk will not cause silicosis. Therefore if this has always been the man's occupation he could not have acquired this disease. Gardner (*Amer. Rev. Tuberc.*, 1923, 7, 344) proves in a classic experiment that finely divided powder of carborundum failed to produce silicosis despite the sharp-edged nature of its particles. It was following these observations that the "solubility theory" of silicosis developed. On the other hand the grinding of iron may cause a fine dust of this metal, which is opaque to x-rays, and long-continued inhalation may give the appearance of reticulation in the x-ray. This, however, would not be associated with symptoms or with fibrosis in the lungs.

INCOME TAX

Addition to Partnership

R. A. inquires whether, in the case of an additional partner entering a firm, "it is usual for the old partnership to be wound up and the accounts closed, or do the old partnership accounts continue?" He also asks how this question affects the liability of the new partner.

•• Whether the old accounts be closed or not is a matter of arrangement between the partners. It is difficult to say what is the "usual" course, but where the old firm has been assessed to income on a "cash receipts" basis, the tendency is to avoid closing the old accounts, as that would involve changing the basis of assessment over to "gross earnings." R. A. will be assessable not as an individual but as a member of the firm, and will have to bear tax on his share of the firm's assessment. His interest in this question is therefore the same as the interest of the other members of the firm.

Depreciation of Car

N. P. sold his car (on which the standard wear and tear allowance had been claimed and given in past years) in March, 1946. A depreciation allowance has been refused for 1946-7.

•• That is correct. Under the Income Tax Act, 1945, depreciation allowance is to be calculated on the value of the "plant and machinery" as at the end of the "basic year." Presumably in N. P.'s case the basic year did not end until after the car was sold, and consequently there was no value on which to calculate the allowance for 1946-7.

LETTERS, NOTES, ETC.

The "Silver Ring"

The honorary secretary of the Family Planning Association writes from 69, Eccleston Square, S.W.1: The medical committee of this society feels that a warning should be given to practitioners concerning the sudden revival of popularity of a method of contraception called the "silver" or "Grafenberg" ring. This appliance consists of a small spiral or other type of ring composed of silver, platinum, or some other suitable metal, which is inserted into the uterine cavity, where its presence, provided it is retained, is intended to prevent the embedding of the fertilized ovum. The advantages of such an unexact method of contraception are so manifest that the device was fairly widely studied some fifteen years ago, both here and on the Continent. Unfortunately, the risks involved in its use have proved greater than were at first anticipated. In addition to the fact that even in cases where the ring is retained the failure rate is high (5% at least; the ring often being born with the baby) the incidence of pain, menorrhagia, and metrorrhagia have been considerable, and subacute infections, acute salpingitis, etc., have been caused in healthy nulliparous women. Moreover, the device entails the utmost danger to women who have previously had, or who contract, gonorrhoea. One such case was reported which necessitated subsequent hysterectomy. Within the last few months, this device has achieved an alarming popularity, for certain practitioners claim it to be the method of choice, even for young nulliparous brides. Members of this committee have met with many cases of infective lesions occurring in such patients, which they will be happy to publish if it appears necessary. It is very difficult for the medical practitioner to obtain guidance on such a matter, and, without it, he is at a great disadvantage when his patients claim to have had friends who have been highly delighted with the method. In point of fact, no progress has recently been made in improving the essentials of the ordinary contraceptive technique: viz, for security, either some type of occlusive rubber cap must be used by the wife in conjunction with a chemical spermicide; or a sheath, preferably with a spermicide, must be used by the husband. Such methods are non-injurious, and offer a high percentage of safety (98% at least used over 10 fertile years), provided they are competently chosen and applied.

Severe Pre-eclamptic Toxaemia with Separation of Retina

Dr. JAMES A. WATERMAN writes from Trinidad: A 38-year-old married woman was admitted to the Colonial Hospital, Port of Spain, on May 16, 1945. With her first pregnancy twelve years previously the patient had suffered from toxæmia; child living. The present history was that she was seven months pregnant, and had had no antenatal care. She complained of generalized swelling of the body for three weeks and total blindness for seven days; bronchitis for two weeks. Examination on admission revealed numerous rhonchi in the lungs, and nothing abnormal in the heart. The urine was solid with albumin, and the pus present was very

offensive. Blood urea 0.033%. Blood pressure 230/150. An ophthalmoscopic examination by Mr. V. M. Metivier gave the following result: "Retinitis of pregnancy marked, papilloedema very marked in both eyes; retinal detachment in lower quadrant of right eye; extensive retinal detachment of left eye, several patches of exudate and a few haemorrhages; condition indicates profound toxæmia of pregnancy." The patient refused immediate operation. She became delirious on May 21, aborted on May 23, and died on the 25th.

Effects of Penicillin Lozenges

Mr. W. E. THOMPSON (Huddersfield) writes: Your correspondent, answering a question on the incidence of complications following oral penicillin treatment (Sept. 21, p. 447), concludes that the occurrence of stomatitis and glossitis from this cause is a rarity since only four cases have so far been reported. In the few months which have elapsed since penicillin became readily available to the public outside hospital this troublesome complication has necessitated suspension of treatment in three of my own cases and has been observed by some of my medical colleagues to whom I mentioned the cases in conversation. The patients were (1) an adult male with severe acute tonsillitis, (2) a young woman with chronic pharyngitis and subacute rheumatism, and (3) a middle-aged woman with aphthous buccal ulceration associated with early pregnancy. In all three the glossitis was very striking, and in the second case the degree of exfoliation was so marked as to cause the patient's relatives some alarm. Different batches of penicillin lozenges were employed for all three cases. None has been noted so far in children who in the main have received this form of local penicillin therapy more than adults. Judging by the complete absence of any such manifestation in a wide use of penicillin parenterally in hospital, often in massive dosage, it seems improbable that the responsible agent can be anything other than some impurity in the lozenges. Some direct evidence would, however, be welcome as to its nature and mode of action. These few remarks seem justified by the epithet "rare" applied by your correspondent to a complication which almost every doctor must now have seen. The inference is that the *rara avis* is not the clinical case but the medical practitioner who, under the harassing conditions imposed by modern panel practice, can find either the time or the inclination to record and ventilate his personal observations.

Dr. T. V. COOPER (Dorchester) writes: The implication of the answer (Sept. 21, p. 447), under the above heading, is that glossitis and stomatitis following the use of penicillin lozenges are very rare, but my experience would lead me to believe that the figure of 18% mentioned in the question is very near the truth. It is certainly the case that the incidence is high among one's fellow practitioners and nursing staff using this form of therapy, but I believe that this is merely due to the fact that these patients are more observant and more constantly observed. In the *British Medical Journal*, 1946, 1, 924, under the heading "Reports of Societies. Medical Uses of Penicillin," Sir Alexander Fleming commented that: "Penicillin lozenges were useful, but in certain patients produced an unpleasant stomatitis. Here again, while the streptococci disappeared from the mouth, their place was taken by penicillin-insensitive organisms, which might be worse for some patients than the streptococci." My limited observations have failed to confirm this explanation, and it is my belief that the source of the trouble lies in the lozenge base both by virtue of its mechanically irritating properties and the fact that there is sugar present, which is likely to irritate by its osmotic effect. During the war, in conjunction with some American colleagues who were in the district, I made some penicillin lozenges with a gelatine base, and about thirty so far as I know, which were treated with these, showed no complication. Thirty cases is a small number, but I feel convinced that if thirty cases were treated with the B.P. lozenge and carefully observed some instances of glossitis would probably be found. I observed complications so frequently that I hesitate to recommend the use of the present commercial lozenge until either the base is altered or some other reason for the glossitis is conclusively found.

Dr. W. T. S. McKEAN (Belfast) writes: In view of your statement in "Any Questions" (Sept. 21, p. 447) that only four cases of glossitis following treatment with penicillin lozenges have so far been reported I feel that I should put on record my own experience. Recently a rather active period in a long history of chronic tonsillitis prompted me to try penicillin lozenges. I consumed thirty-four lozenges in three days and then I stopped because my tongue was distinctly painful. During the next seven days the hard palate and then the angles of the mouth were involved, and it was only after ten days that I was able to smoke and drink normally hot fluids with comfort. Although the condition is unpleasant for the patient it can hardly be considered by the doctor as serious, and I feel that for this reason the incidence of glossitis and stomatitis is probably greater than the cases so far reported would indicate.

Medical Journals Wanted

Dr. DONALD PATERSON of 27, Devonshire Place, Wimpole Street London, W.1, informs us that the medical library of the University of Manitoba has during the war been unable to obtain, or has lost, copies of the following journals:

British Heart Journal, 1939, 1, No. 3 (July); 1942, 4, No. (July), (both out of print). B.M.A., Tavistock Square, London W.C.1.
British Journal of Experimental Pathology, 1937, 18, No. 3 (June 1935, 16, Nos. 1 (Feb.), 2 (Apr.); 1942, 23, No. 3 (June). H. I. Lewis & Co., Ltd., 136, Gower Street, London, W.C.1.
British Journal of Urology, 1942, 14, No. 2 (June). John Wrigg & Sons, Ltd., 28, Orchard Street, Bristol, 1.
British Medical Bulletin, 1943, 1, Nos. 1, 2, 4 (out of print 3, Hanover Street, London, W.1.
Glasgow Medical Journal, 1941, 18, No. 4 (Oct.), (out of print Alex. MacDougall, 104, West George Street, Glasgow, C.2.
Irish Journal of the Medical Sciences, 1945, No. 8 (Aug.). Cahill & Co., Ltd., Parkgate Printing Works, Dublin, Ireland. London 1, Farnival Street, E.C.4.
Guy's Hospital Reports, 1939, 89, No. 2 (Apr.); 1942, 91, No. (Apr.), (both out of print). Guy's Hospital, London, S.E.1.
Journal of Laryngology and Otology, 1941, 56, No. 3 (Mar.), (out of print); 1945, 60, Nos. 1-5 (Jan.-May). Headley Bros., 10 Kingsway, London, W.C.2.
Lancet, 1945, 2, No. 14 (Oct. 6). 7, Adam Street, Adelphi, London W.C.2.
Nature, 1927, 119, No. 14 (Apr. 2), (out of print); 120, No. 2 (Dec. 24), No. 27 (Dec. 31), (out of print); 1944, 153, No. 1 (Jan. 29), No. 6 (Feb. 5), No. 9 (Feb. 26), (out of print); 1945, 156, No. 1 (July 7), (out of print). Macmillan & Co., Ltd. St. Martin's Street, London, W.C.2.
Royal Army Medical Corps Journal, 1944, 83, Nos. 3-5 (Sept. Nov.), (out of print). Staples Press, Ltd., 83-91, Great Titchfield Street, London, W.1.

If any reader has a spare copy of any of these journals Dr. Paterson would be grateful if they could be forwarded to him so that it can help to fill the gaps in the medical library of the University of Manitoba.

Obsolete Addresses

Dr. L. MILLARD (Swynnerton) writes: May I, through your columns, make an appeal to manufacturers of drugs, instruments, etc., to check up through the *Medical Directory* the addresses of those to whom they wish to send advertisements and samples? A conscientious butler spends time almost every day readdressing as posting correspondence of this nature sent to an address which vacated at least five years ago, and I would like to relieve him of this self-imposed task.

Production of Medical Equipment

Dr. D. R. MACDONALD (Edinburgh) writes: Can nothing be done to speed up the production of medical apparatus? For example, it is at present impossible to purchase an ordinary diagnostic set or a Hamblin's ophthalmoscope without having to wait for about a month. I would suggest: (1) that manufacturers be given first priority for the materials which they require; (2) that export of the essential type of commodity be stopped; (3) that surplus Service stocks be at once placed on the second-hand market.

Penicillin in H. influenzae Meningitis: Correction

In a leading article on this subject (Oct. 5, p. 498) an important reference was omitted. The authors to whom credit is due for first observing that meningitic strains of *H. influenzae* are sensitive to penicillin were R. Forgas, R. Irene Hutchinson, and R. E. Rewell (*Lancet*, June 23, 1945, p. 785). They treated two cases of this disease: one died only twelve hours after admission, but the other recovered following combined treatment with penicillin and sulphadiazine. Both strains of *H. influenzae* "were sensitive to penicillin to about the same degree as the standard Oxford strain of staphylococcus." Subsequent detailed studies of more numerous strains have shown that the concentration required to inhibit the growth is usually between 0.5 and 2.0 units per ml. and intrathecal injection is required in order to maintain this concentration. Reference is again made to this subject in our leading article on p. 581 of this issue.

Corrections

We regret that in the *Journal* of Oct. 12 (p. 555 and in table of contents) Dr. C. E. S. Flemming's name was mis-spelt. There was also an error on p. 529 in the spelling of the full name of William Thomas Green Morton.

Bart's men will regret to hear that Sister Theatres is retiring. It is intended to show gratitude for many kindnesses by a small present. Donations may be sent to the Senior Resident Anaesthetist, St. Bartholomew's Hospital, E.C.1.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 19 1946

PLEBISCITE ON THE HEALTH SERVICE ACT
The Memorandum reproduced below has been issued by the Committee of the Bournemouth Division of the British Medical Association to its members, and copies have been sent to secretaries of all the other Divisions in Great Britain.

THE BOURNEMOUTH MEMORANDUM

A plebiscite of all members of the profession will be taken in accordance with a decision of the Annual Representative Meeting of the B.M.A. in July last, on the simple issue of whether negotiations on regulations under the National Health Service Bill with the Minister of Health should take place or not. A vote upon this question will be tantamount to acceptance or rejection by a majority of the profession of the principles and essential structure of the Bill as finally enacted by Parliament. The question will have to be answered by each member of the profession individually. It is therefore vitally important that everyone should clearly understand the issues, for upon the decisions thus made the future of medicine in this country, the position of practitioners and patients, and perhaps much else will depend.

When the voting paper for the plebiscite is issued by the Association it will be accompanied by a statement of the issues, and at least one meeting of members and non-members upon the subject will be held in this, as in other, Divisions. But there may then be little time for coming to a decision, so that it is important for each of us to begin thinking about it now and to discuss it with others. Attention is therefore drawn to the statement by the Chairman of Council published in the *British Medical Journal* on Aug. 3, 1946 (p. 168), and the following considerations are also put forward at this time by the Committee of this Division in the hope that they will be helpful to members and non-members:

Structure of the Service

The structure of the Service as laid down by the Bill (which is not expected to be modified materially before enactment) is as follows:

The Minister of Health will be the supreme controlling authority responsible to Parliament. He will be advised by a Central Health Services Council of which the members (except for certain *ex officio* members) will be appointed by the Minister. The Council will be mainly professional (medical, dental, pharmaceutical, and nursing), but will also contain lay persons with experience in local government or hospital management. The Minister will also be advised directly or through the Central Council by Standing Advisory Committees, appointed by him, on various aspects of the Service. The school, industrial, and certain other medical services will continue to be administered by other Government departments (but may be included later).

The Service will be in three divisions, co-ordinated only through certain personnel and through the Minister, viz.: (a) hospital and specialist; (b) local authority; (c) general medical, dental, and other services.

The *Hospital and Specialist Services* will be organized regionally, or if necessary in certain aspects nationally, with Regional Boards (of which the chairman and members, professional and lay, will be appointed by the Minister) and Hospital Management Committees appointed by the Regional Boards and composed of representatives of local authorities, Executive Councils, and the medical and dental staffs. There will be committees of medical staff as of other "health workers" in hospitals. The method of employment of medical staff remains undetermined. The present endowments of hospitals will be taken into a national fund and redistributed to the Regional Boards and to Hospital Management Committees.

Local Authorities (County or County Borough Councils only) will be responsible for provision and maintenance of health centres and

for certain services, e.g., maternity and infant welfare (apart from hospital), home visiting and help, and ambulance. Experiment will be made in the form of health centres, which will be provided and administered by the local authorities. Doctors using the centres will pay for such use.

General Practitioners (and dentists and pharmacists) will be in contract with an Executive Council on a county or county borough basis. The chairman and some of the lay members of each council will be appointed by the Minister; other lay members, up to 50%, will be nominees of the local authority; the remaining 50% will be medical (appointed by a committee of local general practitioners), dental, and pharmaceutical. General practitioners will be remunerated by basic salary plus capitation. They will not be allowed, under severe penalties, to buy or sell their practices; they will have to obtain permission to practise in any area or to change to another area. If the continued inclusion of any practitioner is considered after inquiry to be "prejudicial to the efficiency of the Service" he may be prevented from further practice in either his own area or any other area, and will have no right of appeal to a Court from the final decision of the Minister. The right of any registered practitioner to enter the Service is not conceded. General practitioners will be compensated if entering the Service on the appointed day (April 1, 1948) for loss of the goodwill of their former practices. Such compensation will be paid in full only on retirement, death, or special necessity; otherwise only interest (2½ p.a.) on the value will be paid.

Private Practice. The right of private practice is conceded but the Minister will control the use of private wards in hospitals and have powers to acquire compulsorily any private nursing institution, and in these and other ways may lessen or remove the facilities for private practice.

How the Principles are Affected

The Principles enumerated by the Negotiating Committee and generally agreed as essential are affected by the Bill as follows:

1. "The medical profession is, in the public interest, opposed to any form of service which leads directly or indirectly to the profession as a whole becoming full-time salaried servants of the State or local authorities."

Under the Bill, general practitioners will be part-salaried State servants with no security against becoming full salaried. Specialists will be remunerated servants of the Regional (State-owned) Hospital Boards. Public health medical officers will, as now, be employees of local authorities.

2. "The medical profession should remain free to exercise the art and science of medicine according to its traditions, standards, and knowledge, the individual doctor retaining full responsibility for the care of the patient, freedom of judgment, action, speech, and publication, without interference in his professional work."

This is not expressly provided for or against in the Bill, but as a salaried or part-salaried servant the doctor's responsibility will be divided between his patients and his employer, the State.

3. "The citizen should be free to choose or change his or her family doctor, to choose in consultation with his family doctor the hospital at which he should be treated, and free to decide whether he avails himself of the public service or obtains the medical service he needs independently."

This freedom is more or less recognized in the Bill but will be obviously limited by regionalization of hospitals and specialist services, the restrictions upon the general practitioner, and the powers of the Minister to limit or abolish private practice.

4. "Doctors should, like other workers, be free to choose the form, place, and type of work they prefer without governmental or other direction."

Under the Bill there will be indirect interference with choice of place of general practice. It appears also that it will be difficult to change from one form of practice to another—e.g., general to special practice.

5. "Every registered medical practitioner should be entitled as a right to participate in the public service."

This has not been agreed.

6. "The hospital service should be planned over natural hospital areas centred on universities in order that these centres of education and research may influence the whole Service."

This has apparently been accepted but the determination of the hospital regions has still to be made. All hospitals will be owned and managed by the State.

7. "There should be adequate representations of the medical profession on all administrative bodies associated with the new Service in order that doctors may make their contribution to the efficiency of the Service."

There will be medical members on the Central Health Service Council and Advisory Committees; also on the Medical Practices Committee and the Regional Hospital Boards and Hospital Management Committees, but they will be appointed by the Minister, not elected. On the Executive Councils (general practice) the medical members will be the nominees of the local medical practitioners. The chairmen of all these councils and committees will be appointed directly or indirectly by the Minister. The Health Committees of the local authorities will not necessarily contain medical members or be advised by a medical committee.

The principal issue is that of the freedom of patient and doctor, whose interests are in fact identical. The institution of a nationally organized medical service has been accepted in principle by the profession. The incompleteness of the service to be provided under the new Act is disappointing but may be corrected in time. The lack of consultation with the profession's representatives in preparing the Bill is deplorable but could not be the basis for standing out of the Service. The acquisition of the hospitals by the State is against the policy of the B.M.A. as determined at the Special Representative Meeting in May last, when the voting against was 210 to 29. Other sections of the profession and existing hospital management committees are not so strongly opposed and State-ownership is supportable logically in a national organization paid for by taxation and compulsory universal insurance. While in existing circumstances, therefore, the hospital position may not by itself be strong enough ground for general opposition to the Bill, it must be taken into account with the other issues.

Threats to Freedom

The freedom of patients and doctors will be imperilled by the following:

1. By the power of the Minister to diminish or abolish private practice, for freedom of choice and action of patient and doctor and freedom in determination of terms and conditions of medical work could be maintained only with difficulty if there were no alternative to the State service.

2. By refusal of the right of any registered practitioner to enter the Service.

3. By employment of doctors by salary whether whole or part-time, since that will mean for the patient divided loyalty on the part of his doctor, and for the doctor at least some measure of control of his life and professional activity.

4. By direction of the general practitioner as to where he may not practise or remove elsewhere to practise.

5. By abolition of the sale and purchase of goodwill of practices severe penalties (new to this country) against infringement.

6. By lack of right of appeal to a Court against the decision of the Minister to forbid continuance (of a general practitioner) in the Service, the effect of which would be removal of means of livelihood, especially if private practice had been eliminated.

7. By the powers of the Minister to appoint chairmen of administrative councils, boards, and committees and members thereof except for a few *ex officio* or otherwise nominated.

8. By the State ownership of all hospitals, making for rigidity of administration and standardization of practice and equipment, with some loss of the personal touch needed in a medical practice; making also for conversion of specialists into whole- or part-time State servants.

In brief, the Bill, while aiming at a more readily available, co-ordinated, and economical medical service for the nation, contains in some of its provisions grave menaces to the freedom of patients and doctors. With this in mind, each one of us must take the responsibility of deciding the attitude of the profession as to whether the Bill, if enacted in its present form,

is acceptable or so unacceptable that it would be inadvisable for the Association to take part in the formation of the regulations under the Act.

NOTE.—The Minister is already proceeding to form the administrative committees of the Service and to invite individuals to take part in them. Attention is therefore drawn to the following resolution passed at the recent A.R.M. by a large majority: "In the view of this Representative Meeting no registered medical practitioners should accept membership of any committee or board established under the National Health Service Act until the results of the forthcoming plebiscite are available."

DORIS ODLUM, Chairman.

N. ROSS SMITH, Secretary.

Bournemouth Division B.M.A.

Sept. 2, 1946.

HEARD AT HEADQUARTERS

Hospital Treatment of School-children

There is still some uneasiness about the payments for the in-patient treatment of school-children under the recent Education Act. The Annual Representative Meeting passed a resolution in which dissatisfaction was expressed, and some Divisions have continued to testify to the apprehension felt by their members, pointing out various inconsistencies in the scale, and urging Headquarters to take the matter up again with the Minister of Education. The Public Health Committee at its meeting the other day received a deputation from the Association of Honorary Staffs of Major (Non-teaching) Voluntary Hospitals, when strong representations were made. A joint committee of the Public Health, Hospitals, and Consultants and Specialists Committees of the Association, with two representatives of the Association of Honorary Staffs, has been set up with a view to reopening the question with the Minister, and it is urged that, as discussions are proceeding, any fresh agreements which are entered into should be specifically stated to be "without prejudice."

A Scottish Impediment

The Scottish Office of the Association has been subjected to some embarrassment, and some Scottish practitioners have experienced disappointment, because it has not been made clear that the Medical Insurance Agency scheme for the purchase of a practice does not apply in Scotland. This is not because the Agency desires to rule out Scotland from the benefit of the scheme: it is due to the state of Scottish law. It will be remembered that the scheme of the Medical Insurance Agency, which the Association recommends, is run in conjunction with the Westminster Bank, which in approved cases is prepared to lend money up to the purchase price on security of the first charge on the practice or partnership and collateral assurance cover for the full amount of the loan. Under Scottish law, however, the goodwill of a practice is not a negotiable asset. Consequently the banks there will not make the advance. This is to be regretted, but it is the actual position; and any grievance is not against those who have introduced the loan scheme, but against the disparity between the legal systems of the two countries. The systems are gradually being co-ordinated, generally by the penetration of English rules into the law of Scotland, but they are not yet so closely related that this scheme is workable north of the Border. It is unfortunate that this has not been made clear in what has so far been published about the scheme.

The Closed Shop

The "closed shop" issue, which has recently assumed a large, if transitory, prominence in this country, has had to be faced by the medical profession in Canada, where the pressure seems to have been successfully resisted and the medical profession to have won the last round. The trade unions have been told in the first place that the medical profession is not a trade and therefore not eligible for trade union membership. In answer to that, of course, it would immediately be pointed out that there are bodies of professional men and women which are in the legal sense trade unions. It was also urged

that doctors could not be bound by hours of service as trade unionists are bound, and that they are fully licensed as a profession at law so that they could not be compelled to join any group; and it was asked what advantages could possibly accrue to local authorities, trade unions, and the public if it was insisted that medical officers employed by public bodies must join a trade union.

In view of the action of a few councils in this country it is proposed that representatives of the B.M.A. should meet representatives of the T.U.C. with a view to the reassertion of the hitherto undisputed claim of the B.M.A., while not a trade union, to speak for the whole profession. Meanwhile the "closed shop" talk seems to be dying down, and the Transport and General Workers Union, which brought the matter forward, is altering its tone. Some decision will be reached by the Trades Union Congress at Brighton at the end of the month.

The "Doctor" Sign on Cars

The retention of the "Doctor" sign on a good many cars has led to quite heated discussions in some quarters. The sign was introduced originally for use in extreme national emergency, but its display now would be hard to justify in many cases. It is not uncommon to find the sign on many cars parked outside a hall where the local doctors are holding a meeting, and it has been seen outside social clubs where the doctor was certainly not attending in a professional capacity. No doubt some case could be made out for its retention because many journeys of the doctor's car are as urgent as those of the ambulance, which carries its own designation. At the same time the use of the sign on ordinary occasions suggests a priority which may be resented by other road users on important business and is not desired by a very large number of doctors. The Executive Committee of the Stratford Division of the B.M.A. has passed a resolution condemning the continued use of the sign and asking the Council to take some action which would discourage it.

Publicity for Penicillin

Complaint is made in one Branch Council at least of the recent announcement in the lay press that penicillin was being released to chemists throughout the country, with the intimation that it would now be available on a doctor's prescription. One objection is that such an announcement, which is of a professional and technical nature, should have been made in the professional, not the lay, press; another, that the announcement suggests that penicillin has been withheld from patients because it is not available to general practitioners; and again it is complained that the announcement has meant that doctors are inundated with inquiries from every type of patient as to whether theirs was not "a penicillin case." The answer might well be that even if the announcement had been made in the professional press in the first instance, it would immediately have been copied in the lay press; that it is well understood that the civilian issue of penicillin was restricted so long as the great need for its use in the Services existed and manufacturers could not fully cope with the demand; and that so far as the conclusions which patients and potential patients may draw from any such announcement are concerned, this would apply to news about any remedy. It is surely for the doctor to explain to his patient, if necessary, the limitations of the new remedy.

Panel Conference Dinner

The Panel Conference, which in recent years has been a rather brief affair, is expected this year to go into the second day. A dinner is to be held—cooks and waiters permitting—on the evening of Oct. 24, when a presentation will be made to Dr. Guy Dain in appreciation of his long and valuable services to insurance practitioners, to which have since been added conspicuous services as Chairman of Council. But this is an insurance practitioners' affair, and the presentation is part of the Dain Testimonial Fund to which Panel Committees subscribed before the war. Owing to the war the formal presentation has not yet taken place.

UNEMPLOYMENT AMONG EX-SERVICE PRACTITIONERS

Attention has recently been focused in the correspondence columns of the *Journal* on the difficulties facing ex-Service practitioners on their return to civil life. The Council of the Association has for some time been aware of deficiencies in the Government's postgraduate scheme for ex-Service doctors and of the urgent need to provide for them suitable and adequately remunerated employment. A special committee of the Association has been considering these and other problems affecting the returning practitioner and has made a number of recommendations which were considered by the Council at its meeting on July 23, as a result of which representations have been made to the Minister on the following points:

(a) That the number of Class I hospital posts under the Government's postgraduate scheme should be increased to enable ex-Service practitioners eligible for such posts to obtain them at a reasonably early date subsequent to their release from the Forces.

(b) That the attention of hospitals be drawn to the fact that there are now full specialists available for appointment to hospital staffs, and it would be both in their own and the national interest to review their staffing position now with a view to restoring it at least to the 1939 level and to increase the hospital establishments where possible.

(c) That a greater number of Class III hospital posts be authorized both in teaching and non-teaching hospitals to expedite the absorption of ex-Service practitioners eligible for such appointments under the Government's postgraduate scheme.

(d) That the present restriction whereby only those ex-Service practitioners who can prove intent to specialize before recruitment to the Forces and who were not established either in general or special practice are immediately eligible for Class III appointments be removed, and that Class III appointments under the Government's scheme be open to ex-Service practitioners who have made progress in the direction of specialism during their service with the Armed Forces.

Word has now been received from the Ministry of Health that authority has been given to a scheme designed to help ex-Service practitioners—both those fully qualified specialists able to take senior posts in hospitals without the need for supervision, and also the more junior specialists not yet qualified to take full responsibility in a higher post. For the former the Ministry proposes to invite local authorities and the larger voluntary hospitals to increase their hospital establishments by creating additional whole-time posts wherever the volume of specialist work justifies it. The salary of these posts will be met from the Exchequer and will be of the order of £1,000 a year. It has been suggested to employing authorities that the selection of ex-Service candidates for these posts should be made in consultation with the dean or director of postgraduate studies of the appropriate university. For the latter the Ministry proposes to enlarge the facilities for postgraduate training both by extending the duration of the appointments and, as far as may be practicable, by addition to the number of posts. The Ministry further states that everything possible will be done to enable ex-Service practitioners to obtain Class I hospital posts under the Government's postgraduate scheme at a reasonably early date after their release from the Forces.

For those ex-Service practitioners who, though unable to prove intent to specialize before recruitment, have attained full specialist status in the Forces, the Ministry has agreed that, subject to approval by the deans and directors of postgraduate studies at the appropriate universities, Class III posts will be made available for them under the Government's postgraduate scheme. Candidates selected by hospitals will, in the first place, serve for a probationary period of six months, which will be extended if the dean or director of postgraduate studies concerned reports that the candidate is suitable for further training.

Discussions are now taking place with the Ministry on the question of affording further specialist training to those ex-Service practitioners who attained graded specialist status in the Forces. The Ministry has, however, pointed out that it is customary in such cases to grant a Class I post for six months on probation with a view to promotion to a Class III post at the end of that period.

Tenure of Appointment in B1 Posts

A communication has been sent to hospital authorities urging that the senior resident hospital appointments, including B1 appointments, which have been held by the present occupants

for two years or more, including those held by alien practitioners, should be re-advertised as soon as the relevant contract or agreement permits in order that demobilized practitioners may have an opportunity of applying for them.

General Practice

The Council of the B.M.A. is aware that the above concessions do not touch upon the difficulties facing those ex-Service practitioners who intend to enter general practice. It wishes to remind this group of practitioners that a special section of the Secretariat has been set up at headquarters to advise on general practice problems, and it welcomes inquiries both from those contemplating taking in, and those desirous of obtaining, partnerships and assistantships.

Association Notices

GROUP OF ANAESTHETISTS

A meeting of the recently formed Group of Anaesthetists within the Association will be held at B.M.A. House, Tavistock Square, W.C.1, on Friday, Nov. 1, 1946, at 2 p.m. All members of the Association who are engaged predominantly in the practice of anaesthetics are eligible for membership of the Group and both those anaesthetists who have already applied for membership, and those who now contemplate joining, are invited to attend.

The agenda will consist of (a) the election of a chairman; (b) consideration of the size of the Group Committee; and (c) a general discussion on the work of the Group.

(Sgd.) CHARLES HILL,
Secretary.

CONSULTANTS AND SPECIALISTS COMMITTEE

As a result of the recently held elections, the following have been appointed representatives on the Consultants and Specialists Committee for the session 1946-7:

Twenty members elected on a regional basis by consultants and specialists who are members of the Association and who are engaged exclusively in consultant and specialist practice:

- Region 1: Dr. A. A. McI. Nicol, Sunderland.
- Region 2: Dr. E. A. Gerrard, Manchester.
- Region 3: Mr. J. T. Morrison, Liverpool.
- Region 4: Mr. D. Watson, Bradford.
- Region 5: Dr. J. W. Brown, Grimsby.
- Region 6: Dr. P. C. P. Cloake, Birmingham.
- Region 7: Dr. Ff. Roberts, Cambridge.
- Region 8: No nomination.
- Region 9: Mr. H. L. Shepherd, Bristol.
- Region 10: Mr. A. L. Abel, London.
Dr. Geoffrey Bourne, London.
Dr. Geoffrey Evans, London.
Sir Cecil Wakeley, London.
- Region 11: Mr. H. J. McCurrah, Hove.
- Region 12: Mr. N. Ross Smith, Bournemouth.
- Region 13: Dr. C. J. Fuller, Exeter.
- Region 14: Prof. G. I. Strachan, Cardiff.
- Region 15: Dr. I. G. W. Hill, Edinburgh.
- Region 16: Dr. W. R. Snodgrass, Glasgow.
- Region 17: No nomination.

Five members elected on a national basis by members of the Association who are engaged part-time in consultant and specialist practice:

- Dr. W. J. Bethune, Inverness.
- Dr. J. W. Buchanan, Edinburgh.
- Mr. W. J. Payne, Darlington.
- Dr. C. B. Prowse, Hove.
- Dr. W. Yeoman, Harrogate.

Diary of Central Meetings

OCTOBER

- 23. Wed. Special Meeting of Council, 12 noon. (Change of time.)

NOVEMBER

- 6. Wed. Ordinary meeting of Council, 10 a.m.

Branch and Division Meetings to be Held

COVENTRY DIVISION.—Tuesday, Nov. 5. B.M.A. Lecture by Dr. Douglas Guthrie.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Medicine.—Tues., 5 p.m. Presidential address by Maurice Davidson: Judgment in Medicine.

Section of Endocrinology.—Wed., 5.30 p.m. Discussion: O activity of the adrenal cortex. Openers, Mr. L. R. Broster (clin aspects), Dr. E. F. Scowen and Dr. F. L. Warren (biochem aspects). Followed by Dr. A. C. Crooke and others.

Section of Urology.—Thurs., 8 p.m. Presidential address by R. H. O. B. Robinson: Some problems of renal lithiasis.

Section of Epidemiology and State Medicine.—Fri., 2.30 p.m. Discussion: Health problems in Germany. Opener, B. J. Kennedy. Followed by Col. Horsburgh and H. A. Raeburn.

Section of Paediatrics.—Fri., 5 p.m. Paper by Prof. Deboi Kala-azar in infancy.

POSTGRADUATE NEWS

A Course of Lectures and Demonstrations will be held at London Chest Hospital on Fridays at 5 p.m. during the Winter Session from Nov. 1 to Dec. 13, and from Jan. 10 to March inclusive. The Course is free to all graduates. Applications should be made to the Dean, London Chest Hospital, Victoria Park, E.2

The Fellowship of Postgraduate Medicine announces the following courses. (1) Week-end course in rheumatism, all day Saturday and Sunday, Oct. 26 and 27, at Rheumatic Unit, St. Stephen's Hospital, Fulham Road, S.W.; (2) course of six lectures on the clinical aspects of psychiatry, on Tuesdays and Wednesdays (afternoons), at Westminster End Hospital for Nervous Diseases, from Nov. 5 to 20.

WEEKLY POSTGRADUATE DIARY

BLACKPOOL: VICTORIA HOSPITAL.—Thurs., 8 p.m. Dr. Bain: Aetiology and Treatment of Appendicitis.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, W.C.—Thurs., 5 p.m. Dr. W. J. O'Donovan: Psychomatic Dermatoses. Thurs., 5 p.m. Dr. G. Duckworth: Virus Diseases of the Skin.

APPOINTMENTS

LONDON COUNTY COUNCIL.—The following appointment has been made in mental health services of the Council at the hospital indicated in parentheses: Medical Superintendent: J. H. Watkin, M.D. (Leavesden).

O'DONNELL, J. H., F.R.C.S., D.L.O., Honorary Assistant Surgeon to the Ear, Nose, and Throat Department, Leicester Royal Infirmary.

PILKINGTON, FRANCIS, M.B., M.R.C.P., D.P.M., Medical Superintendent, City of Plymouth Mental Hospital.

ST. GEORGE'S HOSPITAL, S.W.—Director of Pathological Services, T. Cranle M.D. Assistant Orthopaedic Surgeon, R. H. Young, F.R.C.S. Director Physiotherapy Department, D. C. Shields, B.M., B.Ch. Surgeon-in-Charge Proctology Department, R. Marnham, M.Chlr., F.R.C.S. Ophthalmic Surgeon, J. H. Duggan, M.D. F.R.C.S. Assistant Obstetric and Gynaecological Surgeon, A. H. Charles, F.R.C.S. Assistant Psychiatrist, Sir Paul Mallin, Bt., B.M., B.Ch. Psychiatrist to Children's Department, Emanuel Mill M.R.C.P.

WOOD, E. A., M.D., M.R.C.P., Honorary Consulting Physician, Bea Hospital.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or 18 Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

GRAY.—On Oct. 7, 1946, at the Queen Elizabeth Hospital, Birmingham, to Mr. (née Stanton), M.B., Ch.B., wife of S. C. Gray, B.Sc., Ph.D., a son.

JOSEPH.—On Oct. 4, 1946 at Grosvenor House Nursing Home, Stockport, Enie (née Reubens), wife of Capt. Leslie Joseph, R.A.M.C., a daughter Susan Irene.

MOSELI.—On Oct. 5, 1946, at Carlisle, to Margaret Mary (née Carlyle), wife of Dr. A. Mosell, a daughter—Magdalen.

PLAYFAIR.—On Oct. 3, 1946, at Whitby to Margaretta, wife of Dr. Alexan S. Playfair, a son—Rodney William Sedgwick, brother to David.

PRIEST.—On Oct. 3, 1946, in London, to the wife of Dr. W. M. Priest, a son. REILLY.—On Oct. 9, 1946, at St. Mary's Hospital, W.2, to Joy (née Pea wife of Dr. M. C. T. Reilly, a daughter—Susan Margery.

SCADDING.—On Oct. 12, 1946, at Hammersmith Hospital, to Mabel, wife of Dr. J. G. Scadding, a daughter.

SKINNER.—On Sept. 25, 1946, to Doris (née Wright), wife of Dr. George Skinner, a daughter—Rosalind Doris.

THOMAS.—On Oct. 11, 1946, to Joyce (née Parker Gray), wife of Dr. S. Thomas, M.B.E., a daughter.

MARRIAGES

KONSTAM—RITCHIE.—On Oct. 12, 1946, at Alford, Aberdeenshire, Peter Konstam, F.R.C.S. (Licent.), R.A.M.C., to Sheila T. Ritchie, M.B., Ch.B.

O'CALLAGHAN—LEE.—On Oct. 9, 1946, in Manchester, Dr. W. O'Callaghan Suzanne Lee.

TEMPLEMAN—WILLIAMSON.—On Sept. 7, 1946, at St. Nicholas Cathedral, Newcastle, Geoffrey Hugh Templeman, M.B.E., M.B., of Leeds, to Mrs. A. Williamson (née Thompson), P.M.R.A.F.N.S.

DEATH

WILLIAMS.—On Sept. 29, 1946, at Bars House, Chester, Owen Elias Williams, M.R.C.S., L.R.C.P., aged 58.

LONDON SATURDAY OCTOBER 26 1946

THE BLOOD GROUP Rh*

BY

D. F. CAPPELL, M.D., F.R.S.Ed.

(From the Department of Pathology of the University and Western Infirmary, Glasgow)

PART I

A REVIEW OF THE ANTIGENIC STRUCTURE AND SEROLOGICAL REACTIONS OF THE Rh SUBTYPES

The discovery of the Rh factor illustrates very strikingly how pure scientific research may yield unforeseen results of great practical importance. Physicians who frequently practised blood transfusion had long been aware that, in spite of the most careful matching of the donor's blood by the methods then in use, some patients receiving repeated transfusions became progressively more difficult to transfuse owing to the occurrence of severe reactions. It was also known that such intra-group transfusion reactions occasionally occurred at the first transfusion, but only where the patient was pregnant or had been recently delivered. The finding of "irregular" iso-agglutinins in the blood of such a case had also been recorded (Levine and Stetson, 1939). The term "irregular" implied that these agglutinins did not conform to the scheme of the four blood groups, A, B, AB, O. But these observations remained isolated and uncoordinated until the discovery of the Rh factor by Landsteiner and Wiener in 1940.

These workers observed that the injection of blood from rhesus monkeys into rabbits or guinea-pigs led to the development of antibodies which reacted not only with the red blood cells of those monkeys but also with the cells of 85% of the white population; such persons were termed Rh-positive and the remaining 15% Rh-negative. It is interesting to note that the cells of some primate monkeys—e.g., chimpanzees—are uniformly Rh-negative (Wiener and Wade, 1945). Almost immediately Wiener and Peters (1940) applied the discovery of the Rh factor in man to the identification of the irregular iso-agglutinins found in three sufferers from incompatible intra-group transfusion reactions.† It was shown that all three recipients were Rh-negative, while the transfused blood was Rh-positive; accordingly they explained the intra-group incompatibility by the hypothesis that the Rh factor of the transfused blood had acted as an antigen and had brought about iso-immunization of the Rh-negative recipients. Levine and his co-workers (1941) then demonstrated that the liability to severe intra-group transfusion reactions in the puerperium, usually associated with some foetal abnormality such as hydrops or erythroblastosis, was due to iso-immunization of Rh-negative women by pregnancy with a Rh-positive foetus, and they suggested that not only the maternal transfusion reaction but also the foetal disease was brought about by the action of Rh antibodies. These fundamental observations were quickly confirmed by workers in this country (Boorman, Dodd, and Mollison, 1942; Race, Taylor, Cappell, and McFarlane, 1943), and the various disorders—hydrops foetalis, icterus gravis, and congenital anaemia—were included under the heading "haemolytic disease of the newborn." The significance of iso-immunization of Rh-negative mothers was shown by statistical studies:

thus about 90% of the mothers of infants with haemolytic disease were found to be Rh-negative, while all the infants were Rh-positive.

Wartime difficulties made it impossible for most workers in Great Britain to use immune sera prepared against the cells of rhesus monkeys, but sera from Rh-negative persons who had suffered intra-group transfusion reactions and sera from the mothers of erythroblastotic babies were found to be suitable for the classification of human bloods into the Rh-positive and Rh-negative types. Family studies have shown that the Rh factor is inherited as a simple Mendelian dominant† determined by an allelomorph pair of genes—Rh and rh—but it must be noted that the Rh-negative quality of blood (rh) does not imply merely the absence of the Rh-positive quality (Rh), for it will be shown later that both Rh and rh are responsible for the presence of antigens in the red cells each of which can be detected in specific fashion by its appropriate antiserum. The Rh-rh genes are situated upon a different pair of chromosomes from those for the ABO and MN groups. When an individual possesses two similar genes for a character he is said to be homozygous; when dissimilar genes are present he is heterozygous for that character. There are thus three genetic classes of persons—the homozygous Rh-positive (RhRh), the heterozygous Rh-positive (Rhrh) and the homozygous Rh-negative (rhrh). Further, it will be shown below that Rh and rh are not simple entities, but represent gene-complexes, each of which is composed of three closely linked genes, and some at least of the gene loci are the seat of multiple allelomorphism.

The Discovery of Irregular Agglutinins acting on the Rh-negative Gene Product (rh)

In 1941 Levine, studying the serum from the Rh-positive mother of an erythroblastotic baby, detected a weak agglutinin giving about 30% of positive reactions, which he named anti-Hr because it reacted with all Rh-negative bloods. This was the first instance of an "irregular" agglutinin acting against the Rh-negative component (rh). Further development on these lines by the American workers seems to have been hindered by their possessing at this time only a weak serum which missed many bloods. Details concerning such sera were not published until further and more powerful examples had been found by Waller and Levine (1944) and by Wiener, Davidsohn, and Potter (1945). Meanwhile, independently, a powerful irregular agglutinin was detected by Race and Taylor (1943) in the serum of an Rh-positive mother whose second and third children suffered from haemolytic disease. This serum (then named St after the patient's surname) was proved by a large-scale investigation to react with 80% of all bloods, including all Rh-negative

* A B.M.A. lecture delivered before the Ayrshire Division on Feb. 24, 1946.

† Moureau (1941) made similar observations independently, but his work was obscured by the war.

† It is, of course, recognized that this is not true Mendelian dominance, and that with appropriate reagents both Rh and rh can be detected.

bloods. It was therefore important to know whether this serum would detect the Rh-negative factor where it was associated with a Rh-positive factor—e.g., in the heterozygous state—and this it was found to do. In the first place, certain heterozygotes could be identified on genetic grounds—viz., the Rh-positive children of a Rh-negative parent or the Rh-positive parent of a Rh-negative child—and all of these were found to react positively with the St serum. It was also observed that the reactions with heterozygote bloods were weaker than those with homozygous Rh-negative cells and gave a lower titre or end-point. Consequently it was possible to deduce from the results of titration whether a given blood contained one or two Rh-negative factors reacting with the St serum. This has been termed the "single dose" and "double dose" effect, and explains why Levine's original anti-Hr serum gave such a low proportion of positive results (about 30%); clearly it detected only the "double dose" cells—i.e., the homozygous Rh-negatives (15%) and the type now known as Rh₂ (15%). (Later it was shown that the 20% which reacted negatively lacked the Rh-negative (rh) gene complex—i.e., they were mainly the homozygous Rh₁Rh₁ group—see below.) It is now clear that the anti-Hr sera of Levine and of Wiener are similar to the St serum of Race and Taylor and, accordingly, that Levine's hypothetical Hr factor is merely that part of the Rh-negative (rh) gene-complex which is specifically detected by such sera. Levine and Wiener independently demonstrated that the Hr property behaves, when anti-Hr serum is used to detect its presence positively, as a simple Mendelian dominant, but they have been reluctant to include this property in the Rh scheme of genotypes. To postulate an independent pair of allelic genes for the inheritance of Hr is not sufficient to explain its complex relationships with the Rh genotypes; for a powerful anti-Hr serum like St reacts with approximately 80% of bloods, including both the Rh-positive type and the Rh-negative. Not only must the Hr genes be situated upon the same chromosome pair as the Rh genes but in fact they form an integral part of the Rh gene-complex, as is shown below.

Other Irregular Agglutinins

The intensive study of sera from cases of transfusion reaction and from mothers of infants with haemolytic disease soon revealed the occurrence of other sera possessing very different specificities. In England two sera (identified by the initials K.J.) from Rh-positive mothers of affected infants were found almost simultaneously which reacted with 30% of all bloods, including a very few found to be Rh-negative with the standard 85% sera (Race, Taylor, Boorman, and Dodd, 1943); and shortly afterwards we obtained from a Rh-negative mother who had given birth to a macerated foetus a serum which agglutinated about 70% of all bloods, including about 1% of bloods negative with standard anti-Rh serum (85%) but failing to agglutinate about 15% of bloods positive with the 85% serum (Race, Taylor, Cappell, and McFarlane, 1944). Thus British workers had obtained four separate types of sera containing irregular agglutinins—referred to hereafter as "standard anti-Rh," "80%," "70%" (revised anti-Rh' of Wiener, 1943) (revised anti-Rh" of Wiener) sera. It was also observed that some sera had the properties of two of the four—viz., the standard anti-Rh along with either the 70% or the 30% agglutinin in addition. In America, Wiener (1941) had already found a serum giving only 70% of positives (mainly among Rh-positive bloods), and had named it anti-Rh₂ to distinguish it from the standard serum giving 85% positives. Later Wiener and Sonn obtained a serum that contained two agglutinins of unequal strength both of which acted on certain bloods, and by dilution they were able practically to eliminate the action of the weaker antibody and thus obtain a serum giving only 30% of positive reactions; this they named anti-Rh₁. Wiener had also studied sera containing the 85% agglutinin (standard anti-Rh₁) in good strength together with either (a) the 70% agglutinin or (b) the 30% agglutinin. After some vacillation these double agglutinin sera were finally called respectively anti-Rh₁ and anti-Rh₂ (Wiener, 1944a). It soon became clear that Wiener's 85%, 70%, and 30% sera were in fact the same three single types of agglutinin as were used by British workers, but Wiener did not at that time have the advantage of using a powerful serum acting on Rh₂ and Rh-negative (rh) elements (St=Hr).

By means of his sera Wiener (1944b) was able to subdivide Rh-positive bloods (i.e., those agglutinated by the 85% serum) into three subtypes, which he named Rh₁, Rh₂, and Rh, and also Rh-negative bloods into three subtypes—Rh', Rh'', and rh. Further, he recognized that Rh₁ was closely related in its reactions to Rh', and Rh₂ to Rh''. Race, Taylor, Cappell, and McFarlane (1944) had independently reached similar conclusions, and so, in view of the close concordance of our results with Wiener's, we accepted his terminology, with the minor modification of using Rh₁ for his Rh type. By the additional use of the powerful St serum we were able to detect most of the heterozygotes and thus to identify the genotypes of approximately 80% of persons. In addition, the St serum enabled us to discover a seventh variety of Rh (now called Rh₃) and later to predict the probable existence of an eighth very rare form (Rh₄). Recently a fifth type of single agglutinin serum has been found by Mourant (1945) in a male patient who had received repeated blood transfusions. This serum, like St, reacts with all Rh-negative bloods and with heterozygotes possessing the Rh-negative gene-complex, but it differs from St in failing to react with a proportion of the subtype Rh₂. This evidence points to the probability that the patient himself, and also others whose cells are not agglutinated by his serum, are homozygous Rh₂Rh₂.

Since the Rh factor is genetically determined, it follows that each individual possesses two factors (either or both of which may be a Rh type or rh). One is inherited from each parent, and the overlapping of their reactions makes it impossible in some cases to determine the genotype exactly. Some Rh types are common and others rare, and it is therefore customary to assign each person's genotype to the most common group having the given serological reactions, unless a study of the segregation of the genes in other members of the family enables a more exact allocation to be made. The terminology applied to the individual Rh subtypes and their behaviour with the four single agglutinin anti-Rh sera are set out in Table I: for comparison their reactions with guinea-pigs' anti-rhesus serum are given.

TABLE I.—Human Single Agglutinin Sera

Rh Subtypes	Guinea-pig Anti-rhesus Serum	85% (Anti-Rh ₁)	80% (St: Anti-Hr)	30% (Anti-Rh')	70% (Anti-Rh'')

*Reactions in brackets predicted.

Early Views on Rh₁ and Rh₂ as Additive Types

From the results with 85%, 70%, and 30% sera it would be an attractive supposition that the various Rh types are built up by the summation of two or more of the subtypes—e.g., Rh₁ might be regarded as Rh₁+Rh', and Rh₂ as Rh₂+Rh''; while Rh₃ could be regarded as Rh₁+R'+R''. Wiener (1944a) made this suggestion and proposed that the descriptive terms Rh₁ and Rh₂ should be used. This hypothesis had already been considered by Race, Taylor, and myself, and had been abandoned because the information yielded by St serum ruled out such a simple additive solution. Rh₁ is clearly St-negative, as is Rh'; but Rh₂ is quite certainly St-positive—a fact later confirmed by Wiener, Davidsohn, and Potter (1945) when they had the opportunity of studying the reactions of a powerful Hr (=St) serum on the American negro population, in whom the Rh₂ type is very frequent.

Although Wiener's analysis of the Rh genotypes was at first incomplete owing to lack of a powerful anti-Hr serum, and a serum of Mourant's type, his attempted synthesis of the complexities of the Rh subtypes (Wiener, 1944a) led him to alter the terminology which he had applied originally (Wiener, 1943) to the anti-Rh sera, and so to reverse the designations anti-Rh₁ to anti-Rh', and anti-Rh₂ to anti-Rh''. I had already (1943) made this suggestion independently to Fisher and thereby influenced significantly the development of his analysis and synthesis of the Rh structure.

Fisher's Views on the Rh Structure

The various Rh subtypes cannot be satisfactorily explained by postulating a whole series of allelomorphs at a single locus on the chromosome. The common Rh types, Rh₁ and Rh₂, are not usually attributable to the presence of Rh, on one chromosome and Rh' or Rh'' respectively on the other member of the pair. If Rh₁ were usually equal to genotype Rh₁Rh' and Rh₂ equal to Rh₁Rh'' the offspring of parents of these types would be expected to show separation of the genes, which as a rule they do not: nor is it sufficient to suppose that Rh₁=Rh₁+Rh' at two adjacent loci on the same chromosome: Rh₁ reacts positively with St serum, whereas Rh' and Rh₂ are negative with this reagent. Fisher (Race, 1944) devised a scheme which appeared to cover all the facts then known, but which also made four predictions, two of which have since then been verified—viz., the recognition of a further type of serum (Mourant's anti-e serum) and the identification of an additional type, Rh₃.

Fisher suggested that in each individual the Rh phenotype is determined by three closely linked pairs of allelomorphous genes, which he distinguished by the letters Cc, Dd, and Ee, and he supposed that the gene indicated by each of these six letters determined the presence of a distinctive antigen in the red cells. The triple gene-complexes thus give rise to eight theoretical Rh types by reason of the combination of elementary antigens with which they endow the cells. Seven of these combinations have been recognized by analysis of their reactions with the four antisera, while the eighth has not yet been found segregated in such a way that its individual reactions could be determined. The Rh locus is thus visualized as a strip of chromosome occupied by three closely linked genes. It is attractive to suppose that the rarer subtypes may have arisen by crossing-over during the formation of the gametes. Such a view might explain the great rarity of the R_y type, which would require for its formation crossing-over in persons of rare genotype, or possibly double crossing-over between the three closely linked genes. Fisher and Race (1946) have shown that in Great Britain the frequencies of the rare types R₄, R_z, R', and R'' support such a hypothesis, but proof will be obtained only by statistical analysis of genotype studies in races of widely different Rh constitution.

When Fisher's scheme was first propounded, antisera corresponding to four of the six postulated elementary antigens were known, and it was suggested that sera with specificities corresponding to the other two components would probably be found. This prediction was partially fulfilled by Mourant's discovery of an irregular iso-agglutinin which acted upon all cells containing the antigenic products of the gene-complexes Rh₁, Rh₂, Rh', and rh; while it failed to react with cells of type R₂R₃, R₂R', and R_z. This agglutinin has therefore the specificities predicted for anti-e. It is noteworthy that, like the original St serum (anti-c), Mourant's serum gives weak or strong reactions accordingly as the cells contain one or two "e" components. The discovery of a serum with the predicted specificities is strong support for the view that Fisher's scheme is essentially correct.

According to Fisher's scheme the Cc loci may be occupied by CC, Cc, or cc, the C gene product being detected by anti-Rh' serum (anti-C), while the c gene product is detected by St serum (anti-c). The anti-Rh sera of Levine and of Wiener detect the rh gene product because they, like St serum, act upon component c, as is shown by their positive reaction also with all Rh₁ cells. Race, McFarlane, and Cappell (1945) pointed out that the data given by Waller and Levine (1944) suggested that they were using two distinct kinds of anti-Hr serum, one of which corresponded with the British St serum, while the other, stated to give negative reactions with R,R₁ cells, appeared to be anti-d. Levine (1945), however, acknowledged that a mistake had crept into the data in his paper with Waller and that the reaction with R,R₁ cells should have read *positive* (not *negative* as originally stated). All the American anti-Hr sera therefore seem to have the same specificity and correspond exactly to the British St serum—i.e., anti-c. Anti-d serum still awaits recognition.*

* I am informed by Dr. Race that a serum containing anti-d agglutinin has been found by Diamond and Boyd, but details are not yet available.

Levine (1945) and Wiener (1945d) recognize that Hr is antithetical to Rh' and suggest that the relationship is like that of M and N. Wiener (1945d, Table 12), while not admitting their existence, proposes that the terms Hr', Hr₂, and Hr'' be used if the extension of knowledge requires that Hr be subdivided, the term Hr' being there applied to antigen which was originally called Hr. It seems unnecessary to employ two sets of symbols for the same thing, and in my opinion the term "Hr factor" should now be abandoned as no longer serving any useful purpose. The continued use of this symbol suggests that the Hr factor exists independently of the Rh factor, whereas the position is that Wiener's hypothetical three kinds of Hr factor are merely the three elementary antigens of the Rh-negative gene product, designated by Fisher c, d, and e. Wiener's scheme would mean the employment of two sets of symbols whose interrelationships would not be apparent or else the use of a very cumbersome terminology. Thus type Rh₁ could be represented as Rh₁' or as Hr'', while, by analogy, type rh would be Hr'. Fisher's C D E c d e terminology is neater and gives a greater revelation of the constitution of the Rh type.

Extension of Fisher's Scheme

Recent observations (Callender, Race, and Paykoç, 1945) show that in reality Fisher's hypothesis is an oversimplification, since the category of Rh types has had to be further extended (Callender and Race, 1946; in press).

During the investigation of a series of hitherto unrecognized antibodies in the serum of a young woman who had received repeated transfusions it was proved that one of the new antibodies (anti-Willis) reacted with a second allelomorph at the Cc locus, and this has been tentatively named C_w. Further work has shown that almost 50% of anti-Rh' sera (i.e., anti-C) react with both C and C_w (e.g., the original anti-Rh' serum of Race, Taylor, Cappell, and McFarlane, 1944), whereas the others react only with C. The only pure anti-C_w serum so far recorded is that of Callender, Race, and Paykoç (1945). Since the C component occurs in all Rh₁ and Rh' cells, these types can be subdivided into those possessing C and those with C_w; and the list of Rh genotypes is thus further extended. Race, Mourant, and Callender (1946) estimate that about 2% of persons are of the C_w type; therefore Rh₁Rh₁ individuals may possess two C genes or two C_w genes or one of each, the latter being of genotype C_wDe/CDc.

As is to be expected, anti-Rh₁ sera containing the two agglutinins anti-D and anti-C are also divisible into two types—those whose anti-C component is pure anti-C, and those in which it reacts with both C and C_w. Since C_w is relatively rare it is not clear why anti-C_w should be so often associated with anti-C; and it remains to be proved whether anti-C_w is produced only as a result of iso-immunization by C_w or whether it is produced in a non-specific way as a sort of coagglutinin by the allele C.

It is likely that these antigenic differences are concerned in some of the minor discrepancies which have been observed in the behaviour of different human antisera, and that such differences are responsible for some at least of Wiener's "intermediate" Rh genes. Further work may reveal the significance of occasional discrepancies in the reaction of anti-Rh sera now thought to be identical, and there may be multiple alleles at both the D and E loci as well as at the C locus. Clear proof of this, however, is at present lacking owing to difficulty in obtaining repeated samples of blood from the required cases, but a number of suggestive observations have been made, particularly with regard to the Ee locus.†

Nomenclature of the Anti-Rh Sera

As has been pointed out, much confusion exists about the terminology applied to the various anti-Rh sera—a state of affairs which is not simplified by the fact that some writers in this country have continued to use Wiener's older terminology while others have adopted his newer nomenclature. Stratton (1943) refers to the 70% single agglutinin serum as anti-Rh₁, and calls the double agglutinin serum (87%) anti-Rh', according to the terminology which Wiener (1944a) and I (1944) discarded because it fails to designate the antisera in accordance

† Stratton (1946) has since reported another allele at the Dd locus.

with the antigens with which they react. Fisher (Race, 1944) proposed to name the antisera by the Greek letters corresponding to the elementary antigens of his hypothesis, but this method is troublesome to many workers who are not familiar with the Greek characters. As I originally proposed (Cappell, 1944), the simplest terminology is to call the various sera anti-C, anti-D, anti-E, etc., according to the elementary antigens of the Rh complex with which they react, and this system has the further merit that it is easily adaptable as knowledge advances. It has been approved and adopted by Coombs, Mourant, and Race (1945a, 1945b) and by Race, Mourant, and Callender (1946), and the latter writers have already extended it, as required by the finding of the new allelomorph at the Cc locus.

Murray (1944a, 1944b) proposed to give each of the sera a number and to apply the numbers subscript to the letters Rh in order to indicate the antigenic structure of the type under consideration. Thus: anti-Rh' (anti-C)=serum 1; anti-Rh₀ (anti-D)=serum 2; anti-Rh₁ (anti-C+D)=serum 1 2; anti-Rh" (anti-E)=serum 3; anti-Rh₂ (anti-D+E)=serum 2 3; St serum (anti-c=anti-Hr)=serum 4.

These proposals have not found general acceptance and do not appear to offer any advantage over the terminology proposed above. While new types of antisera could of course be designated by additional numbers, their relationships to those previously recognized could not be so easily displayed as in the above system—e.g., the modification of dividing anti-C into anti-C and anti-C_w.

The alternative nomenclatures of the sera are given in Table II.

antibodies of both anti-D and anti-C type. It is now realized also that the few who appear to have only anti-C agglutinins (70% type) have in fact also been immunized against D. When a Rh-negative person (rhrh) becomes immunized against Rh₁ blood (cDE), however, the antibodies are usually of the anti-D type alone; although sera containing both anti-D and anti-E do occasionally occur, they are rare. It should be emphasized that the D antigen is the only really common and important cause of iso-immunization either in intra-group transfusion reactions or in pregnancy; accordingly, those who lack it may become immunized against it in spite of the presence of other Rh components, C or E, in their genetic constitution. I have previously recorded (1944) the iso-immunization of a mother of type Rh'rh by children of type Rh₁rh; and similar cases have been reported by Simmons and Kelsall (1945) and by Wiener (1945b).

"Incomplete" or Blocking Antibodies

Most workers have been struck by the lack of correspondence between the severity of haemolytic disease in the foetus and the titre of anti-Rh agglutinins in the maternal blood. In some of the most severe cases with repeated obstetric disasters the mother's serum yields only a weak or doubtful agglutination with known Rh-positive cells. This apparent discrepancy has been explained by the observations of Race (1944) and of Wiener (1944c) that, in addition to agglutinating antibodies, maternal sera may contain other antibodies which unite with the receptors of antigen D in the red cells and prevent agglutination by anti-D agglutinating serum. Such interfering sub-

Practical Consequences of the Subtypes

Table I shows that among the eight subtypes of Rh four react positively with the guinea-pig immune anti-Rh serum and that only one of the human iso-immune sera gives the same reactions—viz., the 85% serum (anti-Rh₀). Many workers have included within the classification of Rh-positive all human which react not only with 85% serum but also with 70% 30% sera, but in my opinion this is confusing, and indeed rous. It would be much better to restrict the term "Rh₀" to those cells which react positively with 85% serum i.e., those which contain antigen D. As I have pointed out already (Cappell, 1945), the inclusion of the subtypes R' and R" among Rh-positives constitutes a formidable danger for such individuals, since owing to their lacking antigen D they will develop anti-D just as readily as do Rh-negative persons. If they are reckoned as Rh positive they are liable to be given a transfusion of a true Rh-positive blood, which is incompatible, and this may lead to tragic results if there happens to be anti-D in their serum. On the other hand, although the subtypes R' and R" are both fairly rare (about 1%) it would be wise to eliminate them from the panel of Rh-negative bloods supplied for transfusion, lest they be administered to immunized Rh-negative persons in whose sera there are antibodies of the corresponding type. This danger is much greater with Rh' blood (Cde/cde) because about one-half of the women who become iso-immunized by the Rh₁ gene-complex (CDe) develop

stances have been termed "incomplete" or "blocking" antibodies: they seem to correspond to the old term "agglutinoids." The other Rh antigen receptors—e.g., C or E—are not affected, and the "blocked" cells are thus susceptible to agglutination by sera which act specifically on their unblocked receptors; for example, blocked Rh₁ cells behave like Rh' cells and are agglutinated by anti-C serum; while blocked Rh₂ cells behave like Rh" cells and are agglutinated by anti-E serum.

Coombs, Mourant, and Race (1945a, 1945b) later showed that the union of the blocking antibodies with Rh-positive cells could be demonstrated by washing treated cells free from serum and then subjecting them to the action of anti-human-globulin serum, when prompt agglutination took place. The anti-globulin serum reinforces the action of the maternal antibody presumably by combining with the natural antibody-globulin adsorbed on the surface of the red cells. By this means a very weak antibody may be detected even when present in an amount insufficient by itself to give a distinct reaction. Coombs, Mourant, and Race (1946) refer to this as the *indirect* test, as compared with the *direct* test when the anti-human-globulin serum is added directly to washed cells in order to detect *in vivo* sensitization (see later).

Diamond and Abelson (1945) have pointed out that many of these difficulties can be removed by avoiding the use of saline for diluting the red-cell serum mixtures to be tested. If full-strength maternal serum is mixed with whole blood or

with a cell suspension prepared by dilution in their own serum (Wiener, 1945d) or in a 30% solution of serum albumin. either human or bovine (Diamond and Denton, 1945), rapid agglutination of Rh-positive cells is brought about even when blocking antibodies are present in such amount as to inhibit completely agglutination by the ordinary method. Diamond and Ahelson state that the tests performed on an open slide with albumin solution as a diluent are more rapid and accurate than by any other method, over 99% of sera from Rh-negative mothers of babies affected with haemolytic disease giving positive evidence of Rh antibodies. Albumin solutions of not less than 20% concentration are free from troublesome rouleaux formation, but not all samples of concentrated albumin give equally satisfactory results (Race, Stanbury, personal communication). Rouleaux formation is, however, very troublesome when human serum or plasma is used as the diluent for the cell-serum mixtures, both in the slide test and when performed in tubes as described by Wiener (1945d) under the name of "the conglutination test." When the maternal serum contains only a very weak antibody the results of this test may be equivocal and difficult to distinguish from rouleaux formation, and it is in just such cases that especial difficulty in the interpretation of the other standard tests is encountered. When serum containing only blocking antibodies is incubated with appropriate red cells in saline dilutions the absence of agglutination is attributed by Wiener to the dissociation of a hypothetical protein complex, which he has called "conglutinin," on which the linkage of blocking antibody and red-cell antigen is said to depend. "Conglutinin," in Wiener's sense, is a heat-stable protein, and does not seem to bear any relationship to the complement-like substance to which the name was originally applied (Muir and Browning, 1906). Wiener regards this discovery as the solution of most of the remaining mysteries of the mode of action of Rh antibodies, and has attempted to explain the rapid onset of symptoms after birth as due to the sudden development of "conglutinin" in the postnatal plasma. When the mother's serum is rich in blocking antibodies, however, the foetus often fails to reach full term and is commonly stillborn prematurely, often in a macerated condition with severe erythroblastosis. Miscarriage of a hydropic foetus may occur as early as the fifth month, and it is therefore impossible to accept the view that the interaction of maternal antibodies and foetal cells requires the intermediary action of a hypothetical protein appearing only at or near term.

It is important to note that the open slide test cannot be used alone as a means of analysing the nature of the antibodies present in a serum, because it fails to distinguish between the effects of agglutinating and blocking antibodies. Accordingly, an anti-C serum from an Rh-negative person will by this technique give positive reactions not only with R_1 (CDe) and R' (Cde) cells but with R_2 (cDe) and R_3 (cDE) cells, owing to its content of blocking anti-D, on which its specificity usually depends. For genotype studies and for the analysis of the constituent antibodies the standard test-tube method must be employed, using appropriate Rh types of cells in saline dilutions.

Boorman, Dodd, and Morgan (1945) state that the anti-Rh titre of the maternal serum may be estimated by the tube method, AB serum or plasma being used as the diluent; the results show a much higher titre than in the original saline dilution methods of Wiener (1941) and of Taylor (1943), but among human sera this augmentation of titre is observed only with *iso-immune* sera—e.g., *immune* anti-A and anti-B or anti-Rh—but not with the natural *iso-agglutinins* of human sera. This method may therefore serve to distinguish the natural *iso-agglutinins* from those of immune origin. The adverse effect of saline dilution on anti-Rh sera probably explains why in so many cases of haemolytic disease the maternal serum reacts strongly when mixed with an equal volume of 2% cell suspension but fails to react when diluted 1 in 2 or more. For the actual serum concentration of the mixture is then reduced to 1 in 4 or less. A truer index of the amount of anti-Rh present is obtained by carrying out the titration in serum as Boorman, Dodd, and Morgan (1945) suggest.

"Blocking" antibodies have usually the same specificity as anti-Rh₀ serum—i.e., they act upon antigen D—but they appear to have a greater avidity than the anti-D agglutinins, so that in a mixture they are able to unite with the D receptors first

and thus prevent agglutination. Examples of blocking antibodies with other specificities have been reported by Callender and Paykoç (1945) with the specificity of anti-c (St=anti-Hr), and by Diamond and Abelson (1945) of types anti-Rh₀ (=D), anti-Rh' (=C), and anti-Rh'' (=E).

In some cases of haemolytic disease the cells of the newborn Rh-positive child may be so saturated with blocking antibody that they fail to react with anti-Rh₀ (anti-D serum), and may thus appear to be Rh-negative: they still react, however, with anti-Rh' (anti-C) serum if of Rh₀ type, or with anti-Rh'' (anti-E) serum if of type Rh₁. If recovery occurs the true genotype will be detectable when the child is several months old, after the effects of the maternal antibodies have disappeared. (See Cases 7 and 8.)

Agglutinating antibodies, even when abundant in the maternal blood, can rarely be demonstrated in the foetal serum, but Baar (1945) has shown that blocking antibodies are often present, and can be detected by their capacity to block the "D" receptors of suitable red cells. In view of the alleged greater avidity of "blocking" antibodies, their persistence in the free state in the foetal serum is surprising. Baar has not claimed that in all such cases the red cell receptors of the foetus are fully saturated with blocking antibodies, so that they appear to be Rh-negative, as in Cases 7 and 8 of this series, but this phenomenon was present in some (personal communication).

By means of the rabbit anti-human-globulin serum Coombs, Mourant, and Race (1946) have shown that in all cases of haemolytic disease tested by this method the foetal erythrocytes are found to be sensitized *in vivo* and when washed free from plasma are immediately agglutinated by the anti-human-globulin serum, presumably owing to the presence of absorbed antibody-globulin on the red cell membrane. They refer to this as the *direct* test, and have shown that the cells of an affected foetus which appeared to be Rh-negative (Rh₀rh) were highly sensitized owing to the blocking of the D receptors; after recovery the infant's cells were found to be Rh-positive and of genotype Rh₀rh. Had the direct Coombs test been available when we encountered Case 7 (below) it would have enabled us to detect sensitization of the apparently Rh-negative foetal cells, and would thus have furnished additional proof that this child belonged to genotype Rh₀rh (cDe/cde), like some of the sibs.

Blocking antibodies may appear in the maternal serum instead of agglutinating antibodies, but in some cases they develop later; thus irregular *iso-agglutinins* may be detected in the second trimester of pregnancy, but may be absent at term; nevertheless the foetus will be severely affected. In other cases anti-Rh agglutinins may be present in fair amount during the first one or two pregnancies in which the foetus is affected, but in subsequent pregnancies may be replaced by blocking antibodies. Thus estimation of the anti-Rh titre in pregnancy is a warning only if due attention is paid to the presence of blocking antibodies as well as those of agglutinating type.

It is now recognized that the development of blocking antibodies is a bad prognostic sign and that it is usually followed by the most severe form of foetal disease—e.g., hydrops foetalis.

[Part II, with list of references, will appear next week]

In an address at the annual meeting of the Mental Hospitals Association held in the London Guildhall, Dr. Thomas Beaton, physician-superintendent of St. James Hospital, Portsmouth, said that the adjustment of mental health services to the National Health Service would in many ways be easy as compared with general medicine and surgery. Apart from a few registered hospitals and similar institutions, the mental hospitals service, he said, was already organized nationally. Though there had been local management and development in the different areas, yet under the supervision of the Board of Control, the co-operation of such bodies as the Royal Medico-Psychological Association, the Mental Hospitals Association, and the Union of Mental Hospital and Institutional Workers had brought about a standardization on a national basis far in advance of anything in existence in general medicine and surgery, in fact the new National Health Service could learn much from the experience of the administration of mental health.

THE RECEPTIVITY OF CERVICAL MUCUS TO SPERMATOZOA

BY

MARY BARTON, M.B., B.S.

First Assistant, Fertility Clinic, Royal Free Hospital

AND

B. P. WIESNER, D.Sc.

Consulting Biologist, Royal Northern Hospital

In infecund couples the post-coital (Sims) test often shows that the spermatozoa do not penetrate the cervical canal, or, having penetrated, do not survive therein. Such defective fecundation may be due to seminal deficiency or to abnormal cervical conditions, or both (cf. Miller and Kurzrok, 1932; Lane-Roberts *et al.*, 1939; Green-Armytage, 1943; Siegler, 1944; Barton and Wiesner, 1944, 1945).

Experience has shown that cervical faults are not always apparent. We have seen many cases where spermatozoa of undoubted fecundity (donor's semen) did not penetrate or did not survive in cervical mucus which by all accepted signs (profuse, cell-poor, transparent secretion) presented the fecund appearance associated with the ovulatory phase. It was no longer possible, therefore, in the investigation of a sterile woman, to assume that the cervical mucus was receptive unless the post-coital test was positive—i.e., showed motile sperms in the cervix. In cases of impaired invasion it became necessary to assess the receptivity of the cervical mucus before apportioning responsibility between husband and wife. We therefore attempted to devise a method for testing directly the receptivity of the mucus and the invasive power of the spermatozoa.

Biological Basis of the Invasion Test in Women

During the ovulatory phase a cascade of clear mucus descends from the gaping external os into the vagina. After intercourse the surface of this cascade is in intimate contact with the seminal pool; but the two colloids—semen and cervical mucus—do not mix: they maintain their separate identities. The relative immiscibility of semen and cervical mucus is so pronounced that a drop of one can be centrifuged past a portion of the other. In accordance with the general behaviour of immiscible colloids or liquids, an interface is formed where semen and mucus are in contact with each other. The interface between two such colloids is endowed with properties, such as tension, corresponding with those of surfaces in general. It may be likened to an invisible membrane, and the passage of small particles across such an interface may require an appreciable amount of energy. Suitable *in vitro* preparations, in which fecund semen is brought into contact with healthy cervical mucus, reveal the significance of this interface; for most spermatozoa, on approaching the interface, are retarded or prevented from penetrating. On the other hand, many normal (virile) spermatozoa pass through the interface and survive in the cervical mucus for hours or days. Generally such contact preparations can be used as models of the individual conditions prevailing at the cervical entrance after intercourse or insemination.

Technique in Female Invasion Test

A perfectly clean and grease-free cover-slip is ringed with fine, leaving four narrow gaps. The slip is placed on white paper or a porcelain slab, ringed side up. The cervix is exposed during the presumptive ovulatory phase by a dry unlubricated speculum under good illumination. The protruding cervical mucus cascade is now removed by gentle swabbing with dry cotton-wool, without pressure upon the external os. A small portion of the cascade then still adjacent to the external os is used for the routine test. It is best removed by inserting the tip of a long forceps, opening the blades to a distance of about 3 mm. and closing them again. Thereby the tip of the blades is charged with the small portion of mucus required for the test. When the blades are gently separated above a clean grease-free slide the curious fibrosity (thread-forming capacity) of ovulatory mucus results in the formation of a strand, which is deposited on the slide. The slide is immediately inverted

and pressed lightly against the ringed cover-slip. Thus a capillary chamber, charged with a film of cervical mucus 2–5 mm. wide and about 50 μ deep, is obtained. The chamber must now be charged with semen of established fecundity proved by a recent conception. We use fresh specimens (aged 1 to 6 hours) supplied for, and employed in, A.I.D. (artificial insemination with donated semen). A platinum loop is charged with semen and immediately brought into contact with one of the gaps in the ring. The semen flows by capillary action underneath the cover-slip. By repeating this process the space between the mucus and the edge of the slip is filled. The air escapes through the gaps in the vaseline ring, thus ensuring contact between mucus and semen, without the formation of air bubbles or interstices. The gaps are now sealed with melted vaseline, which must not be hot lest the spermatozoa be damaged. The sealed slide may be kept at room temperature, and is examined on sealing and thereafter at intervals of not more than two hours each. Examination is preferably carried out with a binocular microscope, fitted with a mechanical stage and graduated fine adjustment, so that selected fields and planes can be identified in successive inspections. For quantitative determinations, such as are required for specific research problems, and to acquire familiarity with normal standards, a counting ring has been devised. It is made from a circular cover-slip on which a circle 3 mm. in diameter is drawn with glass ink. This slip is then placed on the diaphragm of the eye-piece; on viewing the slide a circle is thus marked out. The number of spermatozoa leaving or entering the circle per minute is counted. This count directly relates to the density of motile spermatozoa present, and if repeated at intervals yields a measure of invasion and survival. Other specific appliances, such as constant temperature stages, incubators, etc., are not necessary in clinical work; and for routine purposes nothing more than really clean slides, a platinum loop, a microscope, and some patience is required.

Results: Normal Mucus

In a number of cases cervical mucus was removed just before an insemination which resulted in conception; observations in these cases, and in other instances of undoubted fecundity, may serve as standards to be described first. In these cases the sealed preparation has a striking and characteristic appearance. Even macroscopic inspection shows clearly the sharply defined boundary line between the water-clear mucus and the opaque semen. This boundary, far from being obliterated by diffusion of semen into the mucus, grows more pronounced on standing. Microscopically, it is again this boundary between semen and mucus which dominates the picture. At this interface the spermatozoa tend to congregate in dense masses; only a small proportion of highly active sperms pass into the cervical mucus, some almost instantaneously, so that even a few seconds after the slide has been charged sperms are found within the mucus. The subsequent fate of these sperms varies greatly. Many swim about at high speed and, since collisions are less frequent than in densely populated semen, their path is less devious; but it appears to be random, and many sperms pass back into the semen. Other spermatozoa that have also passed through the interface continue to "whip" their tails but fail to show any forward movement. These "oscillatory" sperms may be found anywhere within the mucus, but are most numerous in the field adjacent to the boundary. Yet other sperms, strong enough to break through the interfacial tension, soon lose all motility. Thus a gradient develops; the total density of sperms decreases, but the proportion of motile ones increases, with distance from the interface (see Fig. 1). For the first few hours after the slide has been set up the invasion of the mucus continues. A larger number of sperms invade from than return to the semen, and thus the density of sperms within the mucus increases gradually. After varying periods (2 to 5 hours) a point of culmination is reached. At this stage the seminal fluid contains comparatively few motile spermatozoa, since it has been impoverished by continuous emigration of the most active ones. At the interface the seminal fluid is bounded by a dense felt of spermatozoa, too weak to penetrate the interface, and forming, as they assemble, a growing obstacle to the more active ones on either side of the boundary. On the cervical side a belt of oscillatory or immotile sperms is seen near the interface, the more distant mucus being uniformly

invaded' by motile sperms. This condition characterizes the 'positive' invasion test.

The spermatozoa may continue to live on either side of the interface for 12 to 48 hours at room temperature in such slides; they never survive for 4 to 5 days as they do in the living cervix. The actual period of survival depends on a variety of factors of no present clinical interest. Death of the sperms is often preceded by angulation of the head.

Observations on invasion slides bear upon certain problems of the physiology of fecundation: for instance, there is no evidence that the cervical mucus "attracts" the spermatozoa; the gradually increasing density of the spermatozoa is adequately explained by chance movements—in fact, the interface may be likened to a biological membrane, and the spermatozoa to particles endowed with kinetic energy but moving at random. Though the assembly of sperms at the interface might suggest positive attraction by the mucus, it is more likely that the felt consists of weaklings unable to extricate themselves from the conditions in the boundary phase; for similar congregations can be seen at interfaces between air bubbles and semen, in artificial emulsions of semen, etc. Inanimate particles may congregate in a similar manner (Rideal, 1930).

Sources of Error

It was thought possible that the use of pure semen might be inadvisable, for in human fecundation *in vivo* a pool forms from the semi-liquid contents of the vagina and the ejaculate, and fecundation takes place from this pool; but by using portions of fresh seminal pools in invasion tests the results were not different from those observed with semen itself. More important are errors arising from misinterpretations. Owing to variations in the wetting of the glass slide the cervical mucus may form a film with an irregular outline and narrow indentations, and the seminal fluid is liable to penetrate these crevices (Fig. 2). The resulting intrusion suggests a spearhead of sperms—a veritable "phalanx" or "caravan" penetrating the mucus. Miller and Kurzrok suggested that these intrusions are produced by the mucolytic action of semen and represent the initial stages of sperm-invasion. But careful observation and staining of the semen with carmine show that the phalanges never transgress the boundaries of the semen (revealed by the dye), that no diffusion takes place, and that the sperms *invade individually all along the interface*. In fact, invasion from the phalanges is retarded, probably because of the increased tension in the crevices, which is shown by the alignment of sperms parallel to the closely approximated interfaces between which they are caught.

Results: Abnormal Mucus

In many cases of undoubted female infecundity—e.g., in some women who fail to conceive after repeated A.I.D.—the invasion test is "negative." In such cases the characteristic interface is formed and persists as usual; but the fate of the spermatozoa varies greatly. Neglecting minor deviations from the norm, six fairly definite types of mucus may be distinguished. These are:

1. Spermatozoa pass readily through the interface and penetrate the whole depth of the mucous film. However, they lose motility within 10 to 60 minutes, though some oscillate for longer periods.
2. Spermatozoa pass readily through the interface, but, having invaded to a shallow depth (less than 0.2 mm.), they lose motility, though oscillation may continue for some hours. This type of mucus characteristically shows a reasonably dense invasion limited to the boundary region.
3. Spermatozoa pass through the interface, but lose motility and rapidly cease even to oscillate in the boundary region.
4. Spermatozoa fail to penetrate the mucus; they congregate at the interface, forming the typical felt. Movement along the semen side of the interface may continue for many hours.
5. In rare cases the mucus not only does not admit spermatozoa but appears to affect the boundary region of the semen: for the spermatozoa die soon after their arrival at the interface.
6. In some infecund women the cervix is comparatively "dry"; it yields only small quantities of rapidly drying mucus unsuitable for the test.

These types are, of course, not sharply distinct from each other; thus some specimens of mucus may be virtually non-invadable (type 4), though isolated sperms may penetrate (Fig. 3).

Allowing for such minor variations, the types are not difficult to distinguish after some practice.

Three factors seem to determine the suitability of cervical mucus for fecundation: first, the capacity to allow true (forward) motility of spermatozoa; secondly, the capacity to sustain sperm life, as shown by oscillation and/or forward motility for extended periods; thirdly, the invadability of the mucus. These factors may of course reflect variations involving few or many different physico-chemical properties of the mucus.

Clinical Interpretations of Results

The invasion test was carried out in numerous instances prior to A.I.D., the latter being followed by a Sims test. This series of observations made it possible to relate the results of the test to conditions *in vivo*. It showed that a positive invasion test almost invariably corresponds to a satisfactory Sims test, and that, conversely, the latter reveals inadequate cervical invasion in cases where the invasion test shows defective mucus. Clinical experience thus suggests the interpretation summarized in the accompanying Table, which takes into account both cases of A.I.D. and post-coital tests proper.

Table Summarizing Results

Properties of Mucus <i>in vitro</i>			Sims Test*	Fecundity
Invadability	Sustaining Capacity	Motility Factor		
Present	Present	Present	Deep invasion with good survival of sperms	Present
"	"	Impaired	Many oscillatory sperms in cervix, but few, if any, motile ones	Impaired
"	Impaired	—	Immotile sperms in cervix; often no invasion of isthmus	Absent
Impaired	—	—	Cervix not invaded	"

* Sustaining capacity relates to the capacity of the mucus to maintain the life though not necessarily the forward motility of sperms.

The term "Sims test" applies equally to the post-coital examination of the cervix and to the examination after insemination.

Receptivity of Cervical Mucus in Relation to Appearance and Other Properties

The normal cyclical changes of cervical mucus are well known and have been studied by objective methods (e.g., measurement of recoil; changes in volume and water content: cf. Clift, 1945; Viergiver and Pommerenke, 1946). Hence the determination of physical signs, such as the thread-forming capacity of the ovulatory mucus, might suggest itself in place of the invasion test. As already indicated, our experience has shown that the correspondence between manifest physical signs and biological characteristics is inconstant. Clear elastic mucus ("glair filante") has often given negative results in the invasion test. Thus in cases of manifest chronic cervicitis the mucus may temporarily clear during the ovulatory phase but remain biologically defective. The receptivity of the cervical mucus depends evidently on intimate structure and possibly on chemical factors which are not wholly reflected by the comparatively gross characteristics revealed to the eye or measured by present physical methods.

Frequency of Cervical Dysfunction

In 13 out of 21 women aged less than 35 years who failed to conceive after A.I.D. repeated for three months or longer, cervical invasion was impaired even though other known infecundity factors had been ruled out by the usual tests. Again, taking 50 consecutive cases investigated for sterility in which the Sims test was negative, unsatisfactory invasion tests were obtained in 14 cases. While it is impossible to estimate precisely, at this stage, the frequency of cervical dysfunction, it appears to be common even in the absence of endocervicitis (cf. also Palmer and Palmer, 1945).

Investigation and Therapy

Where the invasion test has given a negative result investigation of the possible causes must be instituted. According to our experience, briefly reviewed below, this task requires that three basic facts concerning the biology of the cervix should be borne in mind. First, that impaired cervical function reflects only, in many cases, general debility with or without specific

disturbances (such as chronic duodenal ulcer, hypochromic anaemia, chronic infective sinusitis, pyelitis). Infection, if present, may have attained a chronic subclinical state yet affect cervical function; this applies particularly to infections of the urinary tract. In many women the cervical secretion is so susceptible to adverse systemic factors that seemingly insignificant ailments must be given due consideration in the investigation. Secondly, adequate cervical secretion depends on oestrogenic secretion (cf. Schroeder, 1928; Wollner, 1936; Barton and Wiesner, 1945). This may be deficient; but in many women with impaired cervical function no general signs of oestrogenic deficiency are present (e.g., hypoplasia); in such cases the deficiency may be caused by a raised cervical threshold to oestrogens, resulting in a decreased rate of mucous flow. Thirdly, the cervix itself may be the seat of an infective pro-

impairment involves a wide field of clinical procedure and access to the appropriate expert opinion.

Specific Therapeutic Measures

1. The administration of oestrone has been found useful in nearly all cases of defective invasion whether other measures were required or not. It was usually given in the form of crystalline suspensions (2 to 4 injections of 1.5 mg. each, during the first half of the cycle). No contraindications to this procedure have been found, though it may delay ovulation by a few days. The increased flow of cervical mucus evoked by oestrone appears to assist any concomitant measures; in some cases no other treatment is required. In the presence of uncomplicated erosions the local administration of oestrone, applied in pessary form, often results in full epithelization and

FIG. 1.—Invasion of receptive ovulatory mucus by spermatozoa (fecund semen). Photomicrograph of unstained live specimen. The interface crosses the field above the arrow on the margin. Note decrease in density of invaders with distance from interface. Mag. $\times 320$; instantaneous exposure. Specimen 12 hours old.

s. In many cases of cervical infection the classical features of inflammation are absent, though routine methods may demonstrate the presence of pathogenic organisms.*

Clinical experience indicates that the impairment of oestrogenic secretion or of cervical reaction to oestrogens may be caused by general factors or infective processes. In other respects, too, the various factors controlling cervical function, and thereby fecundity, are interlinked. In view of the importance of all these factors the proper investigation of cervical

improved cervical function. The pessaries are applied every other evening throughout the cycle and the patient is instructed to douche with warm water on the following morning. With the usual pessaries no effect upon the temperature cycle has been observed.

2. In view of the established efficacy of sulphonamide therapy in cervicitis of gonococcal origin a series of cases of cervicitis of non-gonococcal origin were treated similarly. Sulphonamides were administered orally whether or not other measures (such as cautery or antiseptic applications) were instituted. After initial experiences a number of cases were treated solely with sulphonamides, given orally. The results were to us startling. In numerous instances in which a purulent cervical mucus plug had persisted for years or had recurred after cautery or other measures the cervical mucus assumed normal

* Material for cultures should be taken with the platinum loop and planted immediately upon blood agar. Both aerobic and anaerobic methods should be employed. Incubation should if necessary be prolonged for 48 hours, since the initial growth of organisms obtained from the endocervix or the cervical surface may be inhibited.

appearance, permitted sperm invasion and survival, and pregnancy resulted.

Vaginal cervical cultures have demonstrated a specific pathogenic organism (e.g., *B. coli*) the choice of sulphonamide may be decided. In many cases with a purulent plug in which the mucus had to be presumed sulphadiazine was employed, and in the present case it was recorded that comparatively small doses often suffice. The patient (3 g. daily for five days, no dose being taken after midnight; repeat after a 5-days break. Six pints of blood were transfused daily while taking the tablets, but no alkaline adjustment or change in diet). With this procedure no nausea or other complications were recorded, nor was the normal routine of the patient disturbed. The success of mild sulphonamide therapy seems to us to justify its employment before recourse is had to intensive treatment or other specific measures such as autogenous vaccines, penicillin, etc.

French authors (Palmer and Palmer, 1945) record similar observations. They not only state that chronic endocervicitis is, directly or indirectly, the most common cause of female sterility but also that sulphonamide therapy is successful in about 80% of these cases, leaving a residue of only 20% needing surgical attention.

It may be added that in any woman of child-bearing age in whom surgical measures are contemplated the need for conserving the mucous matrix should be borne in mind. In our experience the milder measures, such as sulphonamide packs, glycerin drains, diathermy, etc., should be tried before any measure involving loss of tissue (e.g., conization). We have seen patients in whom infective processes were effectively dealt with by radical measures at the cost of permanent impairment of secretory function and fecundity.

Invasioo Test in the Male

The technique for testing mucus of doubtful receptivity may be used in the examination of semen of unknown invasive potency. In the present communication only a brief review of the method will be given.

Technique.—Fresh semen obtained by masturbation or taken from a fresh vaginal pool is used; condom specimens are unsuitable. The semen is allowed to liquefy and thus become homogeneous before use. A slide containing fully receptive

mucus is used, and is charged with the semen to be tested. The receptivity of the mucus is established by a control-slide in which it is exposed to fecund semen. Little difficulty was encountered in obtaining suitable mucus; for many female patients attend for their own purposes during the ovulatory phase and consent to supply a specimen of mucus. Several slides containing mucus may be set up and stored in the moist chamber (e.g., a Petri dish) for several hours before use. In all other respects the technique follows the description given previously.

Results.—Nearly two hundred specimens of semen were tested against receptive mucus. From many of these specimens sperms invaded the mucus, with good survival and persistent motility after invasion. These "normal" findings demand no further description.

Several types of impaired invasion and/or viability were noted, however. In the simplest cases the number of invaders was small, both absolutely and in relation to the density of the spermatozoa in the semen. Such deficient invasion is often associated with low viability *in vitro*. In other instances invaders tended to lose forward motility within 60 minutes after penetration. In most of these cases invasion remained

FIG. 2.—Formation of phalanx in negative test (fecund semen). The spermatozoa have penetrated into an interstice between mucus and cover-slip where the latter was not wetted by the former. These deceptive formations do not represent invasion. Mag. $\times 400$. Specimen 12 hours old.

FIG. 3.—Impaired invasion of seemingly normal mucus by spermatozoa (fecund semen). Isolated spermatozoa penetrate the mucus to a shallow depth only. Note "telling" of spermatozoa at the interface. Mag. $\times 400$. Specimen 12 hours old.

shallow. Still more pronounced was the deficiency of semen which provided invaders that became completely immotile almost immediately after invasion. Some specimens contained only isolated sperms capable of invasion or none at all. Lastly, in some specimens viability of the spermatozoa is so low that most of them lose motility soon after emission; and in these cases the usual assembly of sperms at the interface is absent. Apart from non-invasive semen the various types are not sharply differentiated, though by every standard they show greater or lesser impairment of normal behaviour.

The relationship between cytological characteristics of the semen and the invasive potency of the sperms varies widely. In some cases of oligozoospermia invasive potency was higher than in some densely populated specimens; in fact, some of the latter provided no invaders. Generally speaking, the cytological assay of semen does not yield sufficient information concerning the invasive potency of the spermatozoa, on which fecundity depends. On the other hand, high invasive potency does not always balance low density of spermatozoa (oligozoospermia). Our experience suggests the necessity for combining invasion tests with the routine assay of semen.

The treatment of deficient invasive potency is a subject outside the scope of the present communication. It has been referred to by Walker (1945).

Summary

Semen and cervical mucus are virtually immiscible. Fecundation depends on the ability of the sperms to penetrate the interface between mucus and semen. The mode of invasion is described.

This process can be studied individually in special contact preparations, the receptivity of the mucus being assessed by exposing fecund semen, while the semen is assayed against normal ovum.

In many sterile women the mucus does not admit of useful spermatozoa, and these findings are closely correlated with the results of Sims (post-coital) tests.

The non-surgical treatment of cervical dysfunction is discussed, with special reference to sulphonamides.

The authors wish to acknowledge the co-operation of Mr. R. Matson (Royal Surrey County Hospital), who carried out the bacteriological examinations in numerous cases. Details of the bacteriological and other observations will be published in due course.

ACUTE OSTEOMYELITIS OF LUMBAR SPINE IN AN ADULT

BY

HARRY FREEMAN, F.R.C.S.

Surgical Registrar, National Temperance Hospital, London

The following case may be of interest on account of the rarity with which this disease occurs in adults, and because of its close resemblance to tuberculosis of the region involved.

Case Report

The patient, a man aged 43, was first seen in the outpatient department of this hospital on Feb. 8, 1946. He looked very ill, and complained of a painful swelling behind the left hip, the pain being more severe when sitting and at night. He had noticed the swelling three weeks previously, and it had increased in size; his temperature was 101° F. (38.3° C.), he had a dry cough, and night sweats disturbed him considerably. There was no history of trauma.

The swelling was situated a little behind and below the great trochanter to the gluteus maximus muscle (Fig. 1); it was diffuse, and gave the impression that it was connected with the trochanteric bursa of the gluteus maximus. There was deep fluctuation.

Hip movements were free in all directions but caused pain in the buttock. A little irregularity in outline and stiffness in the lower lumbar spine were present, and tenderness on deep pressure in the region of the first and second lumbar vertebrae could be elicited. The patient had lost much weight.

He was admitted to the ward, but a general examination did not reveal any abnormality in the chest or elsewhere, and, in view of the insidious onset and tenderness over the spine, a diagnosis of Pott's disease seemed the correct answer to this problem. X-ray films of the spine showed rarefaction of the upper anterior aspect

of the second lumbar vertebra with possible involvement of the first (Fig. 2). The blood picture showed a severe secondary anaemia with haemoglobin 52%, red blood corpuscles 2,630,000, white blood corpuscles 18,000, of which 87% were polymorphs; the blood sedimentation rate was 67 mm. in one hour. This picture was entirely contrary to expectations, strongly suggesting a pyogenic rather than a tuberculous infection, and on aspiration of the abscess a dirty yellow pus was evacuated which provided a copious growth of *Staphylococcus aureus*. Six days after admission the whole left leg became swollen, and another tender area was discovered on the antero-lateral aspect of the thigh a little below the level of the great trochanter. Under general anaesthesia the original abscess was laid open by a 4-in. (10 cm.) incision, and over a pint (568 ml.)

of pus under considerable pressure was evacuated; exploration with the finger revealed that the abscess was connected with the femoral sheath, seemed to come from the direction of the sacro-iliac foramen. On exploration of the lower part of the wound another abscess cavity was entered, and this must have accounted for the swelling on the antero-lateral part of the thigh. Fifteen ounces (425 ml.) of pus were evacuated from this region.

It would appear that the pus had tracked from its origin in the lumbar spine into the pelvis, along the sacro-iliac foramen, passing through the gluteal region, and then along tissue planes to the front of the thigh, where pressure on the femoral vein resulted in generalized swelling of the limb.

The depths of the abscess cavities were well insufflated with sulphathiazole powder mixed with 100,000 units of penicillin, and a drainage-tube was inserted down to but not through the sacro-iliac foramen. The wound was partly closed with interrupted sutures, dressed, and the patient was returned to bed. A transfusion of two pints (1.14 l.) of blood was given and penicillin in 30,000-unit doses intramuscularly continued four-hourly. The patient was extremely ill, and his condition gave rise to much anxiety; but on the third day after operation the temperature became normal and the pulse improved both in rate and in volume. Penicillin was

FIG. 1.—Showing the position of the swelling.

continued for a further three days following the drop in temperature. A plaster bed was prepared, in which he was comfortably nursed; his general condition showed steady improvement and pain had almost disappeared. The wound was completely healed five weeks after operation. His haemoglobin had now risen to 70%, with red cells at 4,020,000. The spine was again x-rayed, and recalcification as well as some new bone formation was evident; the presence of a small sequestrum was also reported.

The patient was discharged to a convalescent home nine weeks after admission to the hospital, fit, and entirely free from pain; although not yet allowed to walk, he was able to sit quite com-

FIG. 2.—Showing destruction of bone and rarefaction of the upper anterior part of the second lumbar vertebra.

fortably and seemed very anxious to "get going." He was seen again on May 17, after his return from the convalescent home, and he could move about and walk quite freely without discomfort or pain. A further x-ray film on May 31 showed a little more new bone formation.

Comment

The interesting features about this case are the insidious onset, the age of the patient, and the strong resemblance clinically to tuberculous disease of the bone and the development of a very large collection of pus in the presence of a comparatively small area of bone necrosis, as shown by x-ray films.

I would like to thank Mr. D. Denham Pinnock, senior surgeon to the hospital, for the facilities he gave me for dealing with this case, and for his wise counsel throughout; and Dr. Moore Patterson for his great interest and help, and for permission to reproduce the skiagram, which was taken in his department. Lastly, I must not forget the care and devotion shown by Sister Watts, whose nursing largely subscribed to the recovery of this patient.

The Council of British Societies for Relief Abroad (75, Victoria Street, London, S.W.1) states that since the autumn of 1945 members of British voluntary societies have been doing welfare work on behalf of German people living in the larger cities of the British Zone and among the refugees coming in from the East. These workers are grouped in teams numbering about 12 people, men and women with varied training. They represent the British Red Cross and Order of St. John, the Quakers (Friends Relief Service and Friends Ambulance Unit), the Salvation Army, the Girl Guides, the Save the Children Fund, the Catholic Committee for Relief Abroad, and the International Voluntary Service for Peace. Many of these organizations have members serving not only in Germany but also in other countries where there is severe distress—in France, Poland, Austria, Italy, Yugoslavia, and Greece.

NICOTINAMIDE DEFICIENCY AFTER ORAL ADMINISTRATION OF PENICILLIN

BY

P. ELLINGER, Dr.phil., Dr.med., F.R.I.C.

Lister Institute, London

AND

F. MACKENZIE SHATTOCK, M.B., B.S., D.P.M.

Three Counties Hospital, Arlesey, Beds

Diminished urinary output of nicotinamide methochloride in human beings after oral administration of succinyl sulphathiazole or sulphaguanidine has been described by Ellinger, Coulson, and Benesch (1944) and by Ellinger, Benesch, and Kay (1945); and nicotinamide deficiency symptoms have been noted in a case of Flexner dysentery after oral administration of succinyl sulphathiazole by Hardwick (1946). One of us (F.M.S.) has had the opportunity of observing the occurrence of "black tongue" after oral administration of sulphadiazine in one case and of penicillin in another. These cases were reported at the quarterly meeting of the Royal Medico-Psychological Society on Feb. 14, 1946. Quite recently Bedford (1946) reported two cases of "black tongue" after oral application of penicillin, mentioning that he had heard of another. We were able to examine further the patient who had developed "black tongue" after oral administration of penicillin, and it may be of interest to report findings in this case.

The patient was a woman aged 55 employed on administrative duties. She enjoyed good health, but during the war years she had suffered from three mild attacks of nicotinamide deficiency, characterized by lassitude, pellagroid skin changes, erythematous rashes on forearms, legs, and neck, thickening of the skin followed by pigmentation, mild disturbances of deep sensation of the legs with clumsy gait and difficulty in balancing on rough ground, and by abdominal pain and distension. All three attacks were quickly relieved by taking 200 mg. of nicotinic acid daily for four to five days, after which 50-100 mg was taken for a few more days. She had been free from attacks for two years and attributed this to an improved diet—more protein and less carbohydrate.

In October, 1945, she had a mild attack of pharyngitis for which she was given 15 penicillin tablets (Boots) of 500 units each in five days; these were placed on the dorsum of the tongue and allowed to dissolve. They were supplemented by oral administration of penicillin drops containing 500 units per ml. in saline solution pipetted on to the tongue at frequent intervals over five days. At the end of this time the tongue showed a dark slaty colour, which was discovered accidentally on examining the throat. The patient now complained of lassitude, of inability to concentrate on mental work, and of subjective sensory changes in both legs: the legs felt "woolly" and as if they did not belong to her and had to be "placed." The skin of the forearms and back of the hands was dry, coarse, and inelastic.

Penicillin was discontinued and nicotinic acid 200 mg. three times a day was taken for three days: subjective symptoms were relieved and the appearance of the tongue was improved, but brown furring persisted for another two days; the skin of the forearms became normal a few days later.

Effects of Oral Penicillin

The patient was willing to undergo further investigation, so it was decided to observe the effect of oral penicillin on her daily urinary nicotinamide methochloride output, examined by the method of Coulson, Ellinger, and Holden (1944), and to relate this to any clinical changes that might occur. The examination was carried out between Feb. 20 and March 12, 1946.

The daily nicotinamide methochloride output estimated for four days before penicillin administration was 2.40, 2.40, 2.46, 2.01 mg., and on the fifth day the response (actual elimination minus predosing mean elimination) to the ingestion of 100 mg. nicotinic acid was 6.38 mg., equal to 4.55% of ingested nicotinic acid. Penicillin administration was started on March 2, 1946: 34 tablets (Boots) of 500 units each were applied during six days, one at a time, to the left side of the tongue and allowed to dissolve in this position. The urinary output of nicotinamide methochloride fell on the fourth and fifth days of penicillin administration to 1.24 and 1.02 mg. respectively, and

the first symptoms of nicotinamide deficiency occurred. When penicillin was discontinued on the seventh day the nicotinamide methochloride output rose immediately to 2.66 and 2.42 mg. per day, and to 6.46 mg. after ingestion of 100 mg. nicotinic acid, which means a response of 4.08 mg., equivalent to 2.92% of nicotinic acid ingested.

After 11 tablets (thirty hours) the tongue presented the following aspects: a few light-brown patches were seen on the dorsum

Fig. 1

Fig. 2

Fig. 3

Figs 1 to 3. Showing appearance of tongue during the second course of penicillin, reproduced from water-colour paintings made from mirror images: Fig. 1 on third day; Fig. 2 on sixth (last) day of penicillin administration; Fig. 3 on fourth day after discontinuing penicillin. L=left, R=right, side of tongue.

mainly to the left of the midline. These patches could not be removed by washing or scraping the mucous membrane. After the 18th tablet (third day) the dorsum was of a blue-grey cyanotic colour with patchy brown areas (*vide* Fig. 1). After 34 tablets (sixth day) the colour of the dorsum had darkened and the brown areas were now very striking, particularly on the left side (*vide* Fig. 2). They did not extend to the posterior

third. In some places discoloration was punctate and individual papillae brown-topped. The tip, which was denuded of papillae, and the margins were pink. Small venules of a decyanotic colour could be seen coursing over the pink later margins. The tongue was bulky and the fissures were deep than usual.

On the fifth and sixth days of penicillin administration malaise and lassitude were experienced. Mental work deteriorated owing to the difficulty felt in concentrating and in recalling the names of objects and concepts not in constant and familiar use. Recall of the forgotten item had to be aided by a laborious process of association. Subjective sensory change were experienced, and when walking over a rough surface visual aid and a wider base were necessary to maintain equilibrium. The soles of the feet felt "woolly," so that inequalities in the ground could not be easily negotiated. There were also several attacks of epigastric pain, distension without diarrhoea, and urgency of micturition. Slight ataxia was the only neurological sign elicited. On the fifth day an erythematous rash and irritation of the skin of the dorsum of the feet were noted. These symptoms persisted for three days after penicillin was discontinued, while the colour of the tongue faded and a yellow-white fur which could not be scraped off spread over its surface (*vide* Fig. 3). On the ninth day 100 mg. of nicotinic acid given orally caused rapid relief of subjective symptoms, and the tongue appeared normal by the eleventh day.

After discontinuing penicillin the urinary nicotinamide methochloride elimination rose to a higher level than that existing before the experiment (average between March 13 and 21, 4.7 mg./day).

Owing to a misunderstanding urine samples had not been collected during the first days of penicillin dosing; it was therefore decided to carry out another experiment with 24-hour samples of urine, using for the saturation tests parenteral nicotinamide instead of oral nicotinic acid. After three preliminary days (March 29-31, 1946), during which the urinary nicotinamide methochloride eliminations were 4.35, 4.69, and 4.09 mg./day, 100 mg. nicotinamide was given. The response was 19.8 mg. nicotinamide methochloride, equivalent to 13.9% of the administered nicotinamide.

When 100,000 units of penicillin (Glaxo, almost pure) in aqueous solution were ingested by mouth in equal doses from April 3 to 8 inclusive, the urinary nicotinamide methochloride output decreased to 3.12, 2.98, 2.55, 2.27, and 2.55 mg./day respectively. On April 8, 100 mg. nicotinamide was given parenterally; the response (21.1 mg., equal to 14.8%) was similar to that obtained before this course of penicillin was started. After discontinuing penicillin the nicotinamide methochloride elimination fell below the pre-penicillin level, and on April 12-18 (excluding April 17) it was 3.45, 2.18, 1.82, 2.24, 2.63, 2.32 mg./day respectively. On the fourth day of penicillin administration a slight erythematous rash of the face and forearms and mild epigastric pain were noted. Mental dullness and difficulty in concentration were experienced, but the symptoms were much less definite than on earlier occasions. On the fifth day there were awkwardness in walking owing to a "woolly" feeling of the soles, some restlessness, and difficulty in recalling names. The tongue was red, felt bulky and uncomfortable, but showed no obvious change from the normal. On the sixth day there was a light-brown fur on the dorsum of the tongue and the tip was red and denuded of papillae; the skin of the forearms and of the backs of the hands and feet was somewhat dry and inelastic. After 100 mg. nicotinamide intramuscularly all subjective symptoms were rapidly relieved; but the skin of the forearms remained dry, inelastic, and wrinkled for another four days, while the fur on the tongue cleared rapidly.

Discussion

Darkening of the tongue was observed after local treatment of the oral cavity with penicillin in an otherwise healthy person who had previously shown signs of nicotinamide deficiency on several occasions. In a second person a similar appearance of the tongue was noted after oral administration of 20 g. of sulphadiazine for the relief of an infection of the upper respiratory tract. The darkening of the tongue in the latter case was

first observed two days after a three-day course of sulphathiazine had ended. The only other signs noted were dryness and itchiness of the skin. The condition was rapidly relieved by nicotinic acid in both cases. Recently three more cases of darkened tongue were reported by Bedford (1946), and the aetiology of two of these cases was discussed. "Black tongue," which is the sign of canine nicotinamide deficiency, has not, so far as we are aware, been previously described as occurring in human nicotinamide deficiency. In this condition other changes in the appearance of the tongue prevail. In none of the volunteers examined by Ellinger *et al.* (1944, 1945) was black tongue observed after oral administration of succinyl sulphathiazole or sulphaguanidine. The fact that in our case and the three mentioned by Bedford penicillin was in contact with the tongue for a considerable time makes it probable that the changes observed are partly due to a local effect of the drug on the tongue. In the case here described in detail, however, additional signs common in human nicotinamide deficiencies also developed after the oral intake of penicillin. The earlier spontaneous attacks of nicotinamide deficiency and the low response to nicotinic acid before the second course of penicillin, indicated a low nicotinamide status when compared with the normal output and response as described by Ellinger and Coulson (1944), Ruffin, Cayer, and Perlzweig (1944), Coulson, Ellinger, and Smart (1945), and Ellinger, Benesch, and Hardwick (1945). The nicotinamide methochloride output was decreased by the second course of penicillin to a deficiency level, and severe deficiency symptoms were experienced. After discontinuing penicillin the nicotinamide rose to a higher level than before the course. This may have been due to a change of the intestinal flora caused by penicillin. It is now well established that up to two-thirds of orally administered penicillin can reach the colon unaltered (McDermott, Bunn, Benoit, DuBois, and Reynolds, 1946), and the decrease of nicotinamide methochloride output after penicillin is in full agreement with the findings of Ellinger *et al.* (1944, 1945) after the intake of succinyl sulphathiazole or sulphaguanidine.

At the beginning of the third course of penicillin the nicotinamide level was far above the deficiency level, and general deficiency symptoms developed more slowly and were less severe, while the nicotinamide methochloride elimination was similarly depressed but did not fall as low as during the second course owing to the higher initial level. The darkening of the tongue, which had been very marked on the first two occasions when the contact of penicillin with the oral cavity was protracted, was far less noticeable on the third occasion when the contact was only brief.

From the biochemical investigation of the case it is evident that penicillin orally administered can produce a nicotinamide deficiency, as Ellinger *et al.* (1944, 1945) have shown for succinyl sulphathiazole or sulphaguanidine. The degree of the decrease of nicotinamide methochloride output caused by these drugs varies within wide individual limits.

Whether a nicotinamide deficiency develops or not depends on the relative contribution of the bacterial flora to the nicotinamide requirements of the person concerned and on the nicotinamide status of that person: this is evident from the varying reactions of our patient to the three courses of penicillin. The local effect causing the darkening of the tongue has still to be investigated; the appearance of the tongue did not suggest that this darkening was due to a bacterial film but rather to a pigmentation of the papillae. The nicotinamide status of patients treated orally with penicillin should therefore be watched, and if necessary nicotinamide should be given parenterally.

Summary

A case of nicotinamide deficiency after oral intake of penicillin has been described which was characterized in addition to the known nicotinamide deficiency symptoms by darkening of the tongue similar to that observed in another patient after intake of sulphathiazine. In both cases symptoms disappeared after discontinuance of the drugs and administration of nicotinic acid.

We wish to record our thanks to Dr. N. McDiarmid, medical superintendent of Three Counties Hospital, for permission to

publish these cases; to Dr. T. F. Macrae, of Glaxo Laboratories, Ltd., for a generous gift of penicillin; and to the Ella Sachs Plotz Foundation, Boston, for a grant for technical assistance to one of us (P. E.). Our thanks are due to Miss J. Vaughan Morgan for technical assistance.

WORK OF THE GOVERNMENT LYMPH ESTABLISHMENT

JULY, 1898, TO JUNE, 1946

BY

H. S. FREMLIN, M.R.C.S., L.R.C.P., D.P.H.

Formerly Bacteriologist to the Lymph Department of the Ministry of Health

The total number of doses of calf lymph issued from the Government Lymph Establishment between January, 1899, and June, 1946, was 43,804,088, and the number of calves used was 25,350. It is interesting to note that of the total doses issued 21,893,781 went to civilians and 21,910,307 to the Forces.

We began our work at the British Institute of Preventive Medicine at Chelsea, later known as the Lister Institute of Preventive Medicine. Previously vaccination was carried out chiefly from human lymph. The vaccinator inoculated it from arm to arm in children; the cases were examined a week later and the child that produced the best vesicles was selected for the vaccination of the next group of children. Any excess of this good lymph was collected either in capillary tubes or on small ivory or bone slips pointed at the end on which the lymph was removed. These were then put round the rim of a plate to dry; when dry they were kept in a box or paper holder for use when required.

At that time Dr. Cory, assisted by Dr. Stott and Mr. Savory, had an establishment known as the Animal Vaccine Station at Lamb's Conduit Street, where calf lymph was used for those who preferred it. One calf was vaccinated every week and yielded sufficient lymph for direct vaccination and for collection in tubes. These tubes were sent to the Local Government Board and were examined by Mr. Farn, I think for the presence of blood; and if blood was found they were rejected. The advantage of calf lymph was that such diseases as syphilis were avoided. Nevertheless, whether the lymph was obtained from children or calves, bacteria were introduced with the vaccine and might set up inflammation, at times with serious consequences.

In Germany and in France it was found that vaccine could be diluted with six times its weight of 50% glycerin in sterile water and still be equally active—this, of course, allowing of a great saving of lymph. The Local Government Board sent Drs. Copeman and Blaxall to make inquiries on the spot, and they reported favourably on this method. Dr. Copeman investigated the effect of the glycerin on the bacteria contained in the vaccine, and found that though the lymph showed numerous bacteria before the glycerin was added they had almost disappeared within a month without any loss of potency on the part of the lymph itself. The dilution of 1 in 7 of the lymph added greatly to the amount available for use, and this was important when hundreds of thousands of cases were vaccinated every year. It took a long time to collect lymph direct from a vesicle in its pure state, and this would have made it impossible to provide the number of tubes required—about 2,000 a day and possibly twice as many—during a smallpox epidemic.

For calf inoculation a good quality of lymph was essential. When we started work at Chelsea we used calf lymph at first,

but as ours failed we obtained supplies from both Germany and France. That from Cologne was the best. Our stock of lymph was kept at 50° F. (10° C.) and it was potent for six weeks at this temperature. In this connexion, thanks to the courtesy of the Director of the Lister Institute, I had the opportunity of keeping glycerinated lymph for some hours in liquid air at 300° F. (185° C.) below zero. This destroyed neither the vaccine nor the accompanying bacteria. With regard to the stock lymph used for calf vaccination, we found that rabbit lymph gave good results on calves and so we were able to obtain suitable material.

When we began our work there were four of us on the staff—Dr. Blaxall and myself, a secretary, and a boy to assist us. After about two years an epidemic of smallpox broke out and we required a great increase of staff, not only for calf vaccination and bacteriological investigation, but also for clerical work and dispatch of tubes, and there was much additional work for laboratory assistants.

New Establishment at Hendon

In 1907 the Government Lymph Establishment at Hendon was ready for us. Here we had a large two-storey building for laboratory and clerical work, the clerical department being on the ground floor, the laboratories on the floor above. Near by was a large room for vaccinating calves. Four calf stables, each capable of holding twenty animals, and having lofts for storage, were in the same area, together with a small animal house. The electricity and hot water were supplied from a large building with a staff of engineers. In addition, two senior officials of the establishment lived on the premises. Here we had a permanent staff of thirty, as we had on the premises all the men who attended the calves as well as those who assisted in their vaccination and in the collection of the lymph pulp.

Owing to the poor keeping qualities of calf lymph, which quickly loses potency at normal temperatures, production in the early days was governed by the demand, since it had to be issued as soon as it could be passed through the necessary laboratory tests. This meant that no reserve could be kept to meet sudden demands occasioned by outbreaks of smallpox. Experiments in cool storage were made at first with ice (or ice chests), in which the lymph would keep fresh for about six weeks. Then, in 1902, a cool chamber was hired and lymph was stored experimentally at 22° F. (-5.5° C.). By 1904 these experiments had proved so promising that inquiries were made as to the best refrigeration plant available for the projected new establishment at Hendon. Plans for this building were already in hand. The plant was installed and ready for use when the establishment was opened in 1907. From July 3, 1907, all lymphs were placed in the refrigerator, working below 0° C., as soon as they were collected. Further experiments were made, and it was established beyond dispute that lymph kept continuously below freezing point, would retain its potency for two years or more. Cold storage of vaccine lymph has since become universal.

The introduction of this method of storing lymph made it possible for a reserve to be kept, and material equivalent to over a million doses in various stages of preparation was normally held in reserve to meet sudden demands. The value of this reserve was amply demonstrated at the outbreak of the 1914-18 war, when very large supplies of lymph were needed immediately for the Forces. Between 1914 and 1918 over 600,000 doses were issued. An even better demonstration afforded during the 1939-45 conflict, when not only our Forces but those of our Allies stationed in this country had to be supplied. In addition we supplied 750,000 doses to Scotland during the 1942 outbreak of smallpox there, as well as dealing with minor outbreaks in England. Altogether, from September, 1939, to May, 1945, over 15,000,000 doses were issued. At one time during the war our reserve stood at over 5,000,000 doses.

Next to the importance of the discovery of vaccine lymph itself, the introduction of refrigeration must certainly rank second. With its advent an adequate reserve can be kept for emergencies, and production can be spread evenly over a period instead of going up and down with a fluctuating demand. The maintenance of a reserve is very important, as between the

necessity for an increase in production and the material being available for distribution there must always be a time-lag at least a month. This delay is unavoidable. Extra animals have first to be procured, and then kept at least five days quarantine before they are vaccinated. A further few days elapse before the material can be collected, and, after that, there must be allowed for the laboratory tests, tubing, etc.

It is certainly safe to say that without refrigeration the enormous demands of the last war could not have been met and all orders supplied, as they were, on the day of receipt. In conclusion, I wish to mention the work of the secretary Mr. P. W. Sutton, who dealt with the number of calves and tubes required each year, and carried out this exacting work from 1899 to the present time. He has kindly contributed the section above dealing with cold storage.

Medical Memoranda

Novel Method of Digital Traction

In a recent case of multiple compound fractures of the phalanges I hesitated to use the ordinary pulp pin because the pulp of the finger-tips was lacerated and because I did not want to prejudice an already doubtful circulation. At Dr. T. S. Cochrane's suggestion, therefore, I adopted the following method, which I have not seen described and which proved completely satisfactory.

Under general anaesthesia a small hole (about 1/16 (1.6 mm.) in diameter) was bored manually through the central part of the finger-nail by means of a suitable dental drill.

handle. A medium-sized curved cutting needle, threaded with silk thread, was passed proximally between the nail and its bed to emerge through the hole. Sufficient traction was applied to maintain the fracture in the corrected position, and the ends of the silk were tied and fixed to the usual "banjo" splint, as shown in the accompanying photograph. This kept the fracture in satisfactory position for four weeks, without any pain or discomfort to the patient. The expected fraying of the silk against the edge of the nail hole did not occur.

I should like to express my thanks to Dr. Oliver Walker for the excellent photograph.

KENNETH M. MACLEOD, M.D.,
Deputy Medical Superintendent and Surgeon

Dartford County Hospital.

Reviews

RADIOTHERAPY IN MALIGNANT DISEASE

The Results of Radium and X-ray Therapy in Malignant Disease. Second Statistical Report from the Holt Radium Institute, Manchester. 1934-38. Compiled by Ralston Paterson, Margaret Tod, and Marion Russell. (Pp. 145. 7s. 6d. plus 5d. postage.) Edinburgh: E. and S. Livingstone. 1946.

This is an epic account of work done in the Holt Radium Institute before the war. It is a statistical volume showing results in an easily appreciated form, and, so far as the writer of this review can judge, the statistical work has been faithfully carried out and the figures give an undistorted impression of the results. The results are all analysed at least 5 years after treatment, and it is evident that the follow-up organization has been sufficiently good to permit of the loss of a negligible proportion of the patients treated, in spite of the difficulties caused by the war.

In the general survey at the beginning of the report three essentials of cancer work are listed. The first of these is education of patient and doctor, and the report is itself meant to educate both. For this purpose it is divided into three parts. The first is designed to show the organization and results obtained in a manner which can be assimilated by the intelligent layman. Since 1942 there has gradually developed an organization for seeing and treating patients, centred on Manchester and covering a region from Westmorland to Staffordshire, and an increase of from 1,313 to 4,530 patients seen per annum has occurred. A great increase is shown in the proportion of x-ray to radium treatment carried out during the war. The results of the treatment are striking in a disease popularly supposed to be incurable; 40% of about 6,400 patients were alive 5 years after treatment. Tables are given in this part of the report concerning the various sites affected by cancer, and in all of these the importance of early treatment is made obvious.

The second part of the report is concerned with relating results to method of treatment. Certain methods appear to give better results than others. Some of the advantages satisfy tests of statistical significance, but to enable those interested to make up their minds whether the advantages are real or apparent more facts must be given regarding the way in which the treatment is decided. Any such figures as these can only support one method of treatment against another if there has been random selection of cases. Part III of the report shows that a very small proportion of survivors die of cancer after 5 years.

This is the best report of its kind ever seen by the reviewer, and it is to be hoped that other centres will be afforded the necessary facilities to give a similar account of their work.

VOLUNTARY HEALTH WORK IN THE U.S.A.

Voluntary Health Agencies: An Interpretive Study. By Selskar M. Gunn and Philip S. Platt. (Pp. 382. \$3.00.) New York: Ronald Press Company.

In 1941 the National Health Council, assisted by the Rockefeller Foundation, launched a three-year study of voluntary health agencies of the United States. An influential advisory committee was appointed and the results of the survey were sent to forty leaders in the field of health and welfare, who held a two-day conference in New York to discuss them. The study now published is one of the most complete of its kind ever prepared; yet it is remarkable what is left out. Hospitals are not included. All institutions for the custodial care of the sick, dispensaries, clinics, out-patient departments, are ruled out; so are associations formed for supplying group medical service, medical insurance organizations, health services in industrial undertakings. Even professional bodies, such as the American Medical Association, much of whose activity is devoted to serving and protecting the health of the people, are touched upon only incidentally.

What, then, does the survey include? Organizations concerned with health education, community health planning, the combating of certain diseases, and the advancement of research and legislation relating to health. There are 20,000 such voluntary health agencies in the United States. At least 300,000 rather exceptional men and women are giving freely of their

time to the direction of these enterprises, and probably a million others are helping in a less official way. They collect ten million pounds a year from a warm-hearted public. The agencies are the expression of public spirit, pride in a healthy community, a highly developed civic sense. Most of them began with an individual sensitive to a public need who organized a group in his locality, and many expanded into a State or national organization. Thus in Philadelphia in the latter part of the nineteenth century a movement against tuberculosis was started; in New York, the combating of venereal disease; in Connecticut, the promotion of mental hygiene; in many cities, the care of mothers and infants. All these movements presently became national, and so later on did those for cancer control, for the prevention of blindness, for the assistance of the hard of hearing, for public health nursing. One of the most extraordinary developments in recent years has been an organized attack upon infantile paralysis, including research into cause, prevention, and cure. Nothing like this movement, which owes a great deal to the name of Roosevelt, has ever swept over the American scene. It has administrative branches in 36 States, and its separate agencies number 2,600, exceeded only by the tuberculosis associations, national, State, and local, which number 3,000, and the 3,700 chapters of the American Red Cross. On the other hand, for some reason, the most recent national organization, concerned with diabetes, has failed to touch the public imagination. One voluntary agency with national status is the birth control movement, which since 1942 has been the Planned Parenthood Federation of America, Inc. Its battle is not yet won. In Massachusetts doctors are not allowed to prescribe contraceptives, and in Connecticut their use is forbidden.

Many of these voluntary movements when they reach a certain level of public acceptance are taken over by public health departments. The combating of infant mortality is now a Government concern, whereas 35 years ago, in 26 out of 28 of the largest cities of the Union, voluntary agencies were carrying the entire responsibility. In all this absorption there is nothing for resentment. After all, the voluntary movement betokens the interest of a relatively few awakened people; the Government organization means the potential awakening of the whole community. Voluntary effort is, of course, more roving, more experimental, and its value in that respect has to be weighed against the assured support and patronage and (perhaps) more efficient management by the State. Some voluntary agencies have shown a praiseworthy resilience in the face of encroachment. One instance is the House of the Good Samaritan at Boston. It began as a tuberculosis hospital. Then its service was taken over by the State, whereupon it specialized in cancer. The cancer service in turn became a State service, and now the institution is concentrating on cardiac cases and carrying out notable research on rheumatic fever.

In spite of this flow of voluntary service and contribution, those responsible for the survey are by no means satisfied. The agencies are spread unevenly. They offend the natural taste of the administrator for uniformity. They sprang up spontaneously and independently. The wind blew where it listed. The seed was scattered indifferently on all manner of soil. No central direction or planning was attempted. There is duplication here and gap there. Some segments of the health problem are over-served and others not served at all. There is every kind of confusion and waste. The time has come, say the authors of this study, when the voluntary health agencies must reorganize for the task that lies ahead. Their funds must be used more wisely and economically. There must be more team play, more centralized organization and direction. It is, of course, a great gain to efficiency if, instead of competitive appeals, there can be a nation-wide campaign for the proper distribution of health agencies over the entire country, but it may not be altogether good philanthropy. There may be more to be said for the sporadic local effort than these authors realize. If the taking over of voluntary work by the State dries up the springs of private generosity, so does, to some extent, centralized planning in the voluntary field itself. A citizen subscribes to a movement in his own small town for the after-care and relief of crippled children; he does so because the movement serves his neighbours' children and gratifies his local pride, but if in a redistribution this local movement is judged redundant and replaced by something bigger and better fifty miles away he

may not feel the same interest in it. It is well to leave some ends rough-hewn. The authors say that the voluntary health movement has "its fullest flowering in the United States." They can overdo the trimness of the garden.

AFTER-EFFECTS OF TRAUMA OF THE UPPER LIMB

The Traumatic Deformities and Disabilities of the Upper Extremity. By Arthur Steindler, M.D., F.A.C.S., in collaboration with John Louis Marxer, M.D. (Pp. 515; 1048 illustrations. \$10.00 prepaid.) Springfield: Charles C. Thomas. 1946.

Dr. Steindler's well-known eclecticism and catholicism are splendidly displayed in this work. He has set out to discuss not the relatively clear-cut problems of acute trauma but rather the after-effects—the complications of injury. Though "deformity" is a prominent feature, it is rather the disturbances of function that may follow the unsuccessful treatment of injury with which he is more concerned. The author rightly emphasizes how varied may be the disabilities produced by the self-same anatomical lesion and conversely how an identical deformity or disability may result from such very different primary traumatic lesions. In the arm there are particular reasons for stressing function because of its complexity anatomically and physiologically and of its importance to man as a worker.

The mere correction of a malunited radius is of less importance to Steindler than the establishment of a proper physiological usefulness in the limb as a whole. It is, however, not to be supposed that he is only concerned with instruction in the treatment of neglected injuries. While recognizing that the control of infection, the proper alignment of damaged parts, the proper placement of joints with adequate rest to restore biological equilibrium, will prevent future disability, Steindler recognizes that even with perfect primary treatment certain disabilities will still remain.

The work is a mine of information presented largely in the form of case reports. There is a pleasing absence of dogmatism—the cases speak for themselves. Yet we could wish that Dr. Steindler did more often give definite opinion from his vast experience and tell us more about the errors which so often must have been present in the primary treatment before these cases came to him. In a presentation which is patently honest it is inevitable that occasionally it should seem discursive and even incomplete. Nevertheless this is a most valuable study, which all practising orthopaedic surgeons should possess.

If we have one criticism it is with the publisher, who, on the back of the title page, gives stern warning against reproduction of its contents "in any form whatsoever without permission except by a reviewer who wishes to quote extremely brief passages." This is indeed strange in a medical work by a man of such universal sympathy, who has given much to mankind both in originality as well as in what he himself has selected from the writings and practice of other workers the world over.

SOME VICTORIAN MEMORIES

Tooting Corner. By Eric Bligh. (Pp. 336. 15s.) London: Secker and Warburg. 1945.

"The great Victorian age . . .", so Mr. Bligh refers to it; and if its contemporaries were more confident of its greatness than we are, at least we cannot deny that they were accustomed living in the grand manner. "Characters" were as abundant as our gnarled yet shapely English trees, and preached, demed, prayed, bred, built, expressed themselves with a decency and vigour that shame our supposedly uninhibited "century of the common man." *Tooting Corner* teems with such people. The author's father dominates these reminiscences with his forceful personality and masterful appearance; indeed, like so many of the more famous men of his time he seems to have borne a striking resemblance to Landseer's lions. No age is better suited than the Victorian to reminiscence; like a Pre-Raphaelite tapestry the total picture is confusing, overcrowded, whereas the corner revealed in one man's memory is both delightful and indicative of the whole.

Most of Mr. Bligh's ancestors were Dissenters, and his accounts of their chapels, thick black clothes, odour of yellow soap, extemporary and interminable prayers poured forth among pitch-pine walls and imitation morocco bindings, are

recorded with an amused detachment that is likely to be shared by most of his readers. His father, who was a doctor, graduated at Edinburgh, spent several years in Demerara tending natives and preaching to them as persuasively as an ignorant of their language would permit, and finally settled at Tooting, then a country town—where patients seem to have been even more reluctant than usual to pay their doctors' bills. He often, thankless, underpaid work was his lot; a laconic entry in his diary runs: "Miss C. confined, child dead. Mrs. C. lay in bed all day and drinking gin."

Of himself the author says little (the tale ends with his schooldays); but he had the misfortune to be afflicted with a stammer throughout his youth, and the attempts of various doctors to cure it make instructive reading. Perhaps the depths of barbarity were reached by the specialist (described as comparatively eminent authority on stammering) who performed circumcision to loose the wretched lad's tongue. He was finally cured in his later years by psychotherapeutic suggestion.

This is an excellent book for holiday or bed-table. An account of themselves is always educative to doctors; and many anecdotes, digressions, and comments on the life it ended so abruptly in 1914 are stimulating to read.

Notes on Books

Living Together Again, by PHOEBE D. BENDIT and Dr. LAURE J. BENDIT (Gramol Publications, Ltd., 60, Broadway, Chesham Bucks), is a most opportune book, and being priced at only 2s. is within the reach of all whom it concerns. This is important to those who perhaps find it most difficult to resume satisfactory family relationships after long separation are those whose economic situation with the consequent difficulties of finding suitable homes and conditions of life, makes it impossible to find money or time for study of much literature dealing with their peculiar problems. The same reason the advice and explanations given them must be simple, easily assimilated, and amply illustrated by examples. "The human casebook." The authors have succeeded admirably in their task, and those who are experiencing the inevitable difficulties of readjustment will find their own difficulties illustrated by numerous stories of the Johns and Janes, the Williams and M. which are so well told. It is easy to say that patience, tolerance and understanding are all that is wanted, but it is necessary for people to see just how they themselves are to exercise these virtues. Also they must realize that many of their present difficulties do not only from the present circumstances but from old tendencies, habits of mind which have existed in themselves and their parents even perhaps since childhood. The present state of affairs is indeed new, but here, as in everything else, *plus ça change, plus la même chose*. Doctors are constantly being called upon to aid these newly united families in their difficulties, and they would do well to study this little book themselves and tell their patients read it.

Public Baths and Health in England, 16th-18th Century published at Baltimore by the Johns Hopkins Press (\$1.50). Dr. C. MULLETT, the diligent author of this essay on the English balneo of some two centuries, quotes from a bibliography of 238 papers on the subject. Continental wars and international unrest during the sixteenth to eighteenth centuries caused English watering places a boom, especially among fashionable and wealthy folk. A ritual of bathing emerged. Laymen and physicians alike debated the merits of hot and cold baths and their curative qualities. Although in the 1620s Dr. Tobias Venner railed against the number of unlearned empirics and quacks of all kinds who extolled their baths, gracing the medical profession by their "mountbancery," there was little or no attempt at scientific analysis of the waters and their medicinal effects. This essay gives a good description of attempts to establish the whole system of balneology.

The fourth edition of Prof. ALBERT KUNTZ's excellent *Text of Neuro-Anatomy* (Baillière, Tindall and Cox; 32s. 6d.) follows the pattern of earlier editions. Each chapter is clear and ends with a summary and an adequate bibliography. There is a diagram on most pages and everything has been done to present the anatomy of the nervous system in a straightforward way. It is not difficult to divorce structure from function, and although Prof. Kuntz has been concerned with anatomy he has presented it in such a way that the purpose of the form is always evident. The subject is related to the physiology and to the understanding of clinical signs, and in the 26 chapters, besides many with such usual titles as "The Pons" or "Long Conduction Pathways," there are others on "Nervous Integration," "The Functions of the Cerebral Hemispheres," and "Laboratory Study." It would be difficult to conceive a more comprehensive book of its size for the senior student.

LONDON

SATURDAY OCTOBER 26 1946

THE CAPITATION FEE

Insurance practitioners were last month¹ asked to consider a recommendation by the I.A.C. to the Panel Conference that they should place their resignations from the Insurance Service in the hands of the I.A.C. to be used at its discretion

"unless the Minister is willing fully to apply the Spens Report to the current capitation fee, with effect at least from January 1, 1946, or, failing agreement, to refer to the Spens Committee or a representative section of that Committee, or other agreed independent body, the question of the interpretation of the Spens Committee Report in relation to the current capitation fee, both parties agreeing in advance to accept the findings."

The I.A.C. had already in July² criticized the Minister of Health's offer of 12s. 6d. as "gravely inadequate." At the invitation of the Minister, representatives of the Committee met officials of the Ministry on October 10. Sir William Douglas, the Secretary of the Ministry, attended a meeting of the I.A.C. on October 17 and on the next day sent a letter to the Secretary of the B.M.A. (printed in this week's *Supplement*) in which he stated that the Minister was "willing fully to apply the Spens Report to the current capitation fee with effect from January 1, 1946, the increase of 2s. being regarded as a payment on account." The Minister invites the I.A.C. to enter discussions on the Report forthwith "with special reference to the current capitation fee." It is promised that the discussions will be conducted "expeditiously." The I.A.C. decided to recommend the Panel Conference at its meeting on October 24 to accept the Minister's proposal. We go to press before the Conference meets and therefore in ignorance of the Conference's decision. While waiting for this we may note that the Chairman of Council hails this concession of the Minister as a victory for the insurance practitioners of this country. It does indeed show that when the medical profession takes a firm stand on an unambiguous point of principle and fact it can compel consideration of its case. Without prejudging the outcome of the Panel Conference on Thursday it may be helpful to review the events preceding the retreat of the Minister from a position which he seemed at one time to hold tenaciously.

In 1939 the capitation fee was 9s., but insurance practitioners were seriously dissatisfied with much of the evidence which led a Court of Inquiry to fix the fee at this level. In 1942 the figure was increased to 9s. 9d. to meet increased expenses and the situation created by the inclusion in the N.H.I. scheme of non-manual workers with an income of up to £420 a year. Another 9d. in December,

1943, brought the capitation fee to 10s. 6d. It may be recalled that in 1920 and 1921 the capitation figure was 11s. The Insurance Acts Committee did not cease in the early days of the war to voice the complaints of insurance practitioners about the inadequacy of the payment for their work, and in response Mr. Ernest Brown, then Minister of Health, promised that when the war was over the whole question would be investigated "from the ground up." In May, 1944, the Ministry of Health proposed the appointment of the Spens Committee, and the Secretary of the Ministry stated in a letter to the British Medical Association that the results of the proposed inquiry into the remuneration of general practitioners "would be equally valuable and usable no matter what forms of public medical practice may continue or may come into being, under the present law or under any future legislation." In a further letter in July of the same year, the Secretary of the Ministry said that the findings of the proposed Committee would apply "irrespective of the institution of any National Health Service and would directly bear upon existing conditions in the present National Health Insurance scheme." Believing in these assurances the profession agreed to co-operate in setting up the Spens Committee, whose Report was issued in May this year and approved by the profession. The I.A.C. thereupon asked the Minister to apply the findings of the Spens Committee to "existing conditions in the present National Health Insurance scheme." But the Minister refused to do this without at the same time relating the findings of the Spens Committee to the proposed new Health Service. This was in flat contradiction to unambiguous statements previously issued by his Department, and the Insurance Acts Committee therefore refused to negotiate on the basis suggested by the Minister. The Minister, it may be noted, accepted the recommendations of the Spens Committee but would not apply them forthwith to the current capitation fee. But the I.A.C. stood firm, and by his action last week the Minister has acknowledged the error of his ways.

The Spens Committee concluded that in the majority of cases the net income of a general practitioner in 1939 was inadequate to the extent of £200 a year. The only way in which the practitioner in 1939 could have adjusted his income to the level considered to be a meet reward for the work done would have been through an increase in private fees. It is clear that the doctors themselves kept private fees to a level considered to be a fair remuneration for the work they did. Therefore the cause of the inadequacy of income declared by the Spens Committee is the low capitation fee, and the deficit agreed on can be made good only through an adjustment of the capitation fee. In arriving at what the increase should be, consideration must also be taken of the new class of insured persons, the increase in practice expenses, and the altered value of money. The Spens Committee based its recommendations in terms of the 1939 value of money. There is a prevalent misconception that it recommended a capitation fee of 15s. in the N.H.I. scheme. This is not the case. The Spens Committee estimated the outside cost of its proposals for the future to be "15s. a head to provide for the remuneration of general practitioners on the assumption that the number of persons covered by a publicly organized service is

¹ *British Medical Journal*, 1946, 2, 395.

² *British Medical Journal Suppl.*, 1946, 2, 31.

45,000,000" (paragraph 19 of the Spens Report). Again we would emphasize that this figure was arrived at in terms of the 1939 value of money. If, therefore, the Panel Conference has decided that the I.A.C. should negotiate with the Minister on a revision of the capitation fee in terms of the Report of the Spens Committee, it will no doubt insist upon a correct interpretation of the Committee's recommendations.

INFERTILITY

About 10% of marriages in this country are childless—and that without the wishes of the partners concerned. In many others fertility is so low that only one or two children are produced in the course of many years. Some 40,000 to 45,000 of what will ultimately prove to be fruitless marriages take place in England and Wales each year. The figure for the United States of America is about 150,000.¹ Infertility is not necessarily on the increase, but it is more freely admitted. It is so common as to constitute a problem of national importance, although the medical practitioner sees it more often as a problem facing individuals and knows only too well the anxiety, unhappiness, and bitterness that childlessness can cause.

The investigation and treatment of infertility has, in recent years, received considerable attention, and in many centres special clinics are devoted to it. It is no longer enough to dilate the cervix for hypothetical stenosis and to carry out curettage for non-existent "endometritis." Complicated and time-consuming tests of all kinds are often necessary before the cause can be determined and a decision made about treatment. The published proceedings of a conference on the diagnosis of sterility, held in New York in January, 1945,¹ provide a comprehensive and critical review of most of the present-day methods of study of these cases. The subjects of the papers vary from the essentially practical, such as history-taking and tubal patency tests, to the more academic, such as the cause and significance of haemospermia, and include the controversial, such as testicular biopsy. The value of the book is enhanced by verbatim reports of the comments of the many authorities who took part in the discussions after each paper. Both these and the main speakers do not hesitate to report negative findings, and their factual statements and cautious interpretations should act as a corrective to those whose enthusiasm for some special investigation or line of treatment is not always matched by a scientific outlook and due sense of proportion. The paper on the endometrial cycle by Hertig is remarkable for its fine photographs of the different phases, of a 7½-day human ovum previously reported, and also a new 4-day-old human ovum which was found lying free in the uterine cavity.

There is now general agreement that 40 to 60% of the male partners of infertile unions can be shown by semen analysis to have impaired fertility of varying degrees, and this has been emphasized recently in this *Journal* by Jeffcoate.² American workers mostly give the higher figure, and workers in this country the lower, the difference being explained by the fact that the former demand

a higher standard for "normal" seminal values. As long ago as 1904³ Haggart wrote: "... one-third to one-half of all childless marriages are due to the male. . . ." This statement, which passed unheeded or was not accepted for so long, can now be regarded as not exaggerating male responsibility to any extent, and Simmons⁴ is probably right when he says: "Detailed semen study is the most important single clinical detail in the investigation of infertile marriage."

The history of the study of infertility is marked by cycles in each of which the emphasis has been placed on a different causal factor, real or imaginary, sometimes accompanied by a new method of investigation. Salpingography was first attempted independently by Cary⁵ and Rubin⁶ in 1910 and 1915, and tubal insufflation introduced by Rubin⁶ in 1920, have, on the whole, both stood the test of time and experience. Others have not, however; for instance, estimation of the vaginal pH, despite the fact that precoital douches of sodium bicarbonate solution appear to facilitate conception in some cases, has fallen into disuse since it was realized that the vagina never achieves a degree of acidity which is incompatible with fertility. The recognition of the occurrence of anovular menstruation was followed by a phase in which the place of infrequent ovulation as a cause of infertility was probably overstated, although Israel¹ still rates it as high as 15%. Its importance in any case difficult to assess, because menstruation with ovulation, even if demonstrated, may be only a temporary or intermittent phenomenon. Nevertheless some test of the occurrence of ovulation is necessary in the investigation of an infertile woman when no other obvious cause is found, and moreover, from the standpoint of treatment it is important for a woman to know when she is ovulating. The value of daily temperature records in this respect borne out by the experience of Tomkins.¹ A recent trend is to place emphasis on the penetrability of cervical mucus by spermatozoa (see article by Mary Barton and Wiesner at page 606), and the postcoital test, usually associated with the name of Sims or Huhner, has been revived and extended. An "in vitro" modification, usually called Kurzrok-Miller lytic test, is to study the behaviour of spermatozoa brought in contact with cervical mucus on a microscope slide. This has the advantage of making it possible by controlled experiments to say whether it is the mucus or the spermatozoa which are at fault in a case where penetration does not take place. In contrast to the views of some of the enthusiasts for tests of this type, Williams¹ concludes that they are of little practical value and that when there is cervical opposition to the entrance of spermatozoa, then a pathological condition of the cervix, recognizable by ordinary clinical examination, is present.

The study of infertility has naturally involved a study of fertility and has undoubtedly resulted in a considerable increase in knowledge regarding the physiology of both male and female genital systems. Unfortunately, however, more accurate diagnosis has not been attended by much improvement in the results of treatment. Of all cases—and these presumably include those in which all that is required

s instruction in the physiology of reproduction or the removal of some simple bar to coitus—Cary,¹ one of the pioneers in the field, estimates that only one-third can be cured. "Cure," however, is a word not easily applied to his condition. The occurrence of a pregnancy after some form of treatment does not necessarily imply any relationship between the two. Indeed all gynaecologists have had frequent experience of cases where a woman admitted for treatment of sterility has proved to be already pregnant. And what is the criterion of a cure of infertility? A single pregnancy, though gratifying to all concerned, cannot be taken to mean that the fertility of either partner is raised permanently or even temporarily. It may be only a chance occurrence after which the partners of the marriage continue to suffer from infertility, though they do not always complain of it, being satisfied to some extent by the one child.

While there is no doubt that cervical dilatation, treatment of cervicitis, tubal insufflation, correction of retroversion, precoital douches of various kinds, etc., have in some cases a therapeutic value, the treatment of infertility is on the whole unsatisfactory. Above all is this true when fertility is so grossly impaired as to constitute, for all practical purposes, sterility; when there is complete obstruction in either the male or female genital tract, or when the production of spermatozoa or ova is totally suppressed. Operative measures for the relief of occlusion of the Fallopian tube, vas, or epididymis are not often successful. However, these lesions are nearly always caused by gonorrhoea, tuberculosis, puerperal infection (especially post-abortion) or pelvic peritonitis secondary to appendicitis, and it is not unreasonable to hope that in the future they will be prevented. If they are, then the total number of cases of infertility and sterility will be reduced by one-third. Also prophylaxis may well have something to offer in those cases when spermatogenesis or ovogenesis is at fault, for there is evidence to show that these are sometimes caused not only by mumps but other acute infections and by general ill-health and endocrine disturbances in childhood and adolescence.

RESEARCH IN CHRONIC RHEUMATISM

As long ago as 1922 the Ministry of Health conducted a sample survey among insured workers to determine the incidence, and cost, of the group of complaints commonly called rheumatism. It was found that this group was responsible in England and Wales for one-sixth of the industrial invalidity, for a yearly expenditure on sickness benefit of £2,000,000, and for an annual loss of 3,000,000 weeks of working time. More recently it has been estimated that approximately one-third of the payments by approved societies under the National Health Insurance scheme are made in respect of conditions labelled "chronic rheumatism." While its severity ranges from slight inconvenience to dire crippling, the prevalence of the disease in adult and early adult life—during the productive and reproductive years—presents an enormous and costly burden, with serious effects on society as a whole, on industry, on the home, and on family life.

The Medical Advisory Committee to the Ministry of Health recommended in 1945 that a number of diagnostic and research centres should be established for the study of chronic rheumatism and for the improvement of existing facilities for

diagnosis and treatment. Improved methods of diagnosis and treatment, though they may lead to the alleviation of much suffering, will not in themselves bring about any diminution in the incidence of the disease. This can result only from fundamental research into the causation and nature of the disease process. For this reason it was proposed that the special centres should be located in university medical schools and teaching hospitals, where resources are available for a combined attack on the disease in all its forms.

A rheumatism centre of the kind contemplated by the Ministry is to be established at the University of Manchester, with the assistance of a grant from the Nuffield Foundation of £100,000 spread over ten years. In broad outline it is proposed to establish a diagnostic and research centre at the teaching hospital—the Manchester Royal Infirmary—to deal with short-stay in-patients and out-patients who will be referred to this clinic from peripheral clinics in the region. For long-stay in-patients there will also be a clinic at a base hospital near the centre, provided by the Manchester Public Health Committee, and a second base hospital in the country—the Devonshire Royal Hospital at Buxton. At the base hospitals lengthy investigations will be carried out and problems of rehabilitation and resettlement will be studied. This scheme will ensure ready access to a very large number of cases of the disease, especially in its early stages; this is a pre-requisite for any successful attack upon its causation, diagnosis, and treatment. At the centre the work will cover two main fields: the clinical, sociological, and industrial aspects of the disease, and the fundamental study of the disease process by pathological, bacteriological, and biochemical methods. The clinical work will be under the direction of a physician who will have the full co-operation of the departments of orthopaedics and physiotherapy of the Manchester Royal Infirmary as well as of the University Dental School. The social aspects of the disease, and its industrial implications, will be studied in co-operation with the University Department of Industrial Health. The basis of all fundamental research into the causes of diseases of the bones and joints is the study of bone and joint pathology; this study will be under the direction of a whole-time pathologist who is an expert in this field.

An important element in the organization of the health services of the area will be the diffusion throughout the area of the expert knowledge gained at the university centre and the bringing of the physicians and surgeons of the peripheral area into closer relation with the medical school. An ultimately wider diffusion will be achieved through the medical school, since its undergraduates will grow up with a better general knowledge of the subject.

PRESSURE DRESSINGS FOR BURNS

On theoretical grounds it is possible to advise conclusively that the application of a pressure dressing to a burn will limit the extravasation of plasma into the burnt area and will consequently prevent part of that diminution of blood volume which is largely responsible for the shock that follows burning. Moreover, pressure dressings have been employed by plastic surgeons for years to increase the likelihood of a skin graft's "taking." The advantage of applying a pressure dressing to a burnt area has now been measured experimentally by Cameron and others¹ in goats, and by Glenn, Gilbert, and Drinker² in dogs.

Already in 1945 Cameron and his fellow-workers³ had shown that prompt application of pressure bandages to

¹ *J. Path. Bact.*, 1946, 53, 1.

² *J. clin. Invest.*, 1943, 22, 609.

³ *J. Path. Bact.*, 1945, 57, 37.

the severely burnt limbs of goats retarded the loss of plasma from blood vessels, diminished haemoconcentration or prevented its occurrence, and favourably influenced the clinical condition of the animals. The same team of workers have now shown by carefully controlled experiments on the lower limbs of goats that the healing of a compressed burn is greatly accelerated and that the increase in the rapidity of healing is independent of sepsis or asepsis. The pressure is applied by the application of quick-setting Gypsona plaster bandages closely wrapped round the burnt limb to leave a considerable overlap beyond the burn margin; a layer of dry sterile gauze separates the plaster from the skin. The control goats received no plaster application but were dressed by sterile gauze kept in position by elastoplast. The animals in both series had their dressings changed frequently and were fully loaded with sulphathiazole. The mean healing times for the two groups were 39.5 ± 1.8 days for the pressure-treated goats, and 63 ± 5.7 days for the controls. This reduction is significant.

The time of application of pressure is of some importance. If it is delayed for more than four hours after the burn is sustained healing is not accelerated, so in clinical practice the pressure should be applied if possible within this period. The duration of maintenance of pressure is equally important. There appears to be a critical phase which lasts for several days after burning and during which removal of the plaster case occasions severe oedema of the burnt area and delay in healing; the pressure should therefore be maintained for some nine days. After nine days it seems of little moment whether it is continued until the sixteenth or the thirtieth day.

On purely theoretical grounds Bingham and Logie independently employed plaster immobilization for burnt extremities sustained in a forward area in Libya in 1942, and there was a clinical impression then, statistically unsupported, that healing was accelerated, the patient's comfort improved, and the general condition ameliorated by this simple measure. However, there is argument now for the widespread application of plaster-of-Paris pressure to burns recently sustained.

DUST REDUCTION IN MINES

Among the most important measures for the prevention of pneumoconiosis in miners are the use of water for dust reduction and improvements in ventilation. Water can aid in the reduction of dust in three ways: (1) by suppressing dust already in the air; (2) by allaying dust and thus preventing its dissemination; and (3) by preventing the formation of dust. The influence of increased ventilation on dust concentrations is obvious: if dust production remains constant an increase in the volume of air passing reduces the concentration of the dust; and if increased ventilation is combined with the appropriate use of water still greater reductions in dust concentrations can be achieved.

During recent years much work has been done in Great Britain on the use of mist projectors in suppressing dust, especially at loading points and after blasting. For the effective removal of dust by this method it is essential that the water be discharged into the air in the form of a finely atomized spray; a coarse spray is relatively ineffective. Dust concentrations in the air of mine roadways are much reduced by the periodic application of water to the roads. For several years past wet drilling has been recognized as an important factor in the reduction of dust formation in rock drilling; and it has been shown in Great Britain and the United States that in coal mines and metalliferous mines substantial reductions in dustiness can be brought about by spraying hewn or blasted rock and coal before

they are loaded. During the last few years, in the anthracite mines of South Wales, the infusion of water into the coal face before blasting has done much to reduce the concentration of dust at that point.

In two recent papers Tebbens and Tabershaw¹ have given further evidence of the effects of the use of water and increased ventilation on the dustiness of mine air. The data were obtained from two surveys of concentrations of air-borne dusts in a group of haematite mines. At the time of the first survey water was available for use in drilling, but owing to prejudice against it most of the drilling was done dry; and only limited amounts of water were used in dumping ore. In the interval between the two surveys the widespread use of water for dust control was introduced. Drillers were educated and persuaded to use water; in ore-handling operations water was used to wet the broken rock, and the main haulage-ways and headings were regularly damped.

These measures proved very effective. They reduced the dust exposure of drillers by about five-sixths, and substantially reduced the exposure of other workers. The dustiest operations in these mines are those connected with loading "muck," and although on this work the use of water reduced the dust concentrations by more than one-half further reduction was necessary to render the work reasonably free from the risk of silicosis. The desired result was obtained by providing increased ventilation. In the stopes where this work was carried on the average dust concentration was 153 million particles per cu. ft. (28,300 c.c.m.) when the quantity of air passing was below 1,000 cu. ft. per min., but when the air supply was raised to 8,000 cu. ft. per min. the average dust concentration was reduced to 25 million particles per cu. ft., which was regarded as the maximum safe concentration for rock containing 15-20% pure silica.

The Association of Anaesthetists of Great Britain and Ireland are next week celebrating the centenary of the first administration of ether in Great Britain. On Wednesday, Oct. 30, the Princess Royal will at the Royal College of Surgeons of England unveil a plaque commemorating four pioneers in anaesthesia. This will be followed by a reception by the President and Council of the College. On Oct. 31 the John Snow Medal will be presented to Lieut.-Col. H. W. Featherstone, Major L. G. Morrison, and Squad-Ldr. E. A. Pask, and in the evening there will be a dinner in the Great Hall of Lincoln's Inn by kind permission of the Masters of the Bench. On Oct. 29 to Nov. 1 there will be an exhibition of anaesthetic apparatus, including Mr. A. Charles King's museum, in the Council Room of the College of Surgeons.

At a special meeting of the Liverpool Medical Institution held on Oct. 19 with the President, Dr. G. F. Rawdon Smith, in the chair, honorary membership of the Institution was conferred upon Dr. A. E. Barclay, F.R.C.P., Sir W. Allen Daley, M.D., F.R.C.P., Dame Louise Mellroy, M.D., F.R.C.P., Prof. Charles McNeil, M.D., F.R.C.P., Dr. Ivan W. Magill, and Sir Alfred Webb-Johnson, P.R.C.S. The six new honorary members were introduced by Dr. Robert Coope, acting as public orator.

Dr. J. C. Spence will give the Charles West Lecture on Tuesday, Nov. 19, at 5 p.m. at the Royal College of Physicians of London, Pall Mall East. Subject: "The Care of Children in Hospital."

ANAESTHESIA CENTENARY CELEBRATIONS

EXHIBITION AT WELLCOME MUSEUM

The centenary of the first surgical operation to be performed under general anaesthesia was celebrated in London on Oct. 16 by the opening of an exhibition at the Wellcome Historical Medical Museum in Euston Road. Dr. E. Ashworth Underwood, director of the Museum, presided, and Lord Moran gave an address.

Lord MORAN said that for ages people had tried to produce something which would permit of operations being done without pain, but the nineteenth century was reached before anything really happened at all. And not only was anaesthesia not being discovered, but when it was announced it seemed to hang fire, first because the drugs were not standardized, and secondly because religious scruples interfered a good deal with their use. Even in Queen Victoria's reign the scripture was read, "In sorrow shalt thou bring forth children," and it was held that there should be no interference with that divine plan. Among preparations for the anaesthetic age were Priestley's contributions to pneumatic chemistry—the study of gases—and Humphry Davy's production and use of "laughing gas." Then there was Hickman's work in the eighteen-twenties which allowed surgical anaesthesia by inhalation to be a practical proposition. But it was left to Wells and Morton to bring the thing about. Wells, apparently, did everything that was necessary, but Morton had the power, to use the modern phrase, to "put it across," and his was the name that 100 years later was associated with this development. Lord Moran added one or two general observations. Progress in medicine, he said, had never been up a smooth incline, but always by fits and starts, with long periods of stagnation and then a sudden jump forward. In spite of what he had said about anaesthesia's hanging fire, its discovery was a gift of everlasting mercy to mankind. It was really no accident, but part of the great crusade of the nineteenth century to improve and humanize the conditions under which people lived and worked and suffered. He looked with profound satisfaction upon the fact that the democracies of Britain and America had taken the chief share in this humanizing process.

The exhibition, which Lady Moran then declared open, is arranged in a most instructive fashion by means of originals, reconstructions and models, photographs and illustrative diagrams, and a wealth of books. One showcase illustrates the knowledge of narcotic and stimulating drugs in primitive times and among the Greeks and Romans; another the days of surgery without anaesthesia; and yet others the therapeutic uses of vapours and gases and ether frolics, the work on inhalation anaesthesia, the development of the anaesthetic uses of chloroform, the introduction and development of nitrous oxide anaesthesia, together with much literature on the subject, including old copies of *Punch* and the *Illustrated London News* showing the early popular reaction to anaesthesia.

Three Periods of Anaesthesia

On the same day a meeting of the History of Medicine Section of the Royal Society of Medicine was held, when Prof. CHARLES SINGER, who took the chair, spoke of anaesthesia in the pre-anaesthetic period (before 1846) and other speakers dealt with the developments in the second half of the nineteenth century and in the first half of the twentieth.

Prof. Singer said that it was an error to suppose that before 1846 operations were always performed on the fully conscious. Narcotics and analgesics were known very early; they were mentioned in Egyptian writings and in the Hippocratic collection. The narcotic drugs of antiquity were mainly of the natural order *Solanaceae*, to which belonged not only mandrake and belladonna, but also the potato, the tomato, and tobacco. The main narcotics available to the people of the Middle Ages were opium, mandrake or belladonna, chiefly the leaves, and hyoscyamus or henbane. The best literary account of the surgical use of narcotic drugs dated from the fourteenth century and was given by Boccaccio in his *Decameron*, in which there was an account of an anaesthetic proposed for the amputation of a leg. Hypnotism was first used in surgical operations by John Elliotson (1791–1862), professor in the University of London and president of the Royal Medical and Chirurgical

Society. A medical observer, Robert Kinglake, had left an account of the effect of nitrous oxide on Humphry Davy and on a number of other persons, and the speaker read some of these extracts. Kinglake afterwards experimented with ether, but did not suggest it for anaesthetic purposes.

Dr. BARBARA DUNCUM read a paper on the development of inhalation anaesthesia down to the turn of the century. She mentioned that by 1850 anaesthetic practice had assumed certain distinctive characteristics in different parts of the world. In the northern States of America ether was used; the southern States traditionally followed the example of Paris in medical matters, and in Paris chloroform was administered from a folded cloth, according to Simpson's directions. The rest of Europe also followed Parisian methods, and in Scotland, of course, Simpson's method reigned supreme. In England a very different state of affairs obtained. Mainly, no doubt, because of John Snow's strong influence, the English from the first considered the giving of an anaesthetic to be a specialist's job, whereas elsewhere it was not considered necessary to employ an expert anaesthetist and the task of administration was usually relegated to a junior house surgeon. Simple and effective as Simpson's method of chloroform anaesthesia was, the English, by the beginning of 1848, had already devised a number of more or less elaborate chloroform inhalers, and Snow was controlling the anaesthetic mixture by regulating the temperature of the vaporizing chamber by a water jacket. Snow's portable regulating chloroform inhaler served his contemporaries as a model until the introduction of Clover's chloroform apparatus in 1862. Clover, after Snow's death in 1858, had quietly become recognized as the leader in anaesthetic practice, and chiefly through him a committee of investigation of the Royal Medical and Chirurgical Society carried out experiments on ether and chloroform which resulted in a new and more flexible attitude towards anaesthetic questions in British practice, with the realization that no single agent could be expected completely to satisfy every requirement.

Dr. JOSEPH BLUMFIELD followed with a recital of the various steps in the development of anaesthetics since 1900. He mentioned the use of ethyl chloride in America, France, and Germany in the early years of this century, the use of prolonged nitrous oxide and oxygen in America about 1913, the practice of synergistic analgesia in America about 1923, and the work of Leonard Hill and Dale on the advantage of N_2O under pressure. About 1925 explosion dangers from static sparks were very much in the public mind, and precautions were taken. Dr. Blumfield also touched on the introduction of the new basal narcotics, and closed with some reflections on the more co-operative and understanding attitude of the patients to-day as compared with their ignorant fears of anaesthesia in earlier days.

First Use of Inhalation Anaesthesia in Britain

Finally Dr. E. ASHWORTH UNDERWOOD supplemented his paper in the *British Medical Journal* of Oct. 12 by giving the details of what appears to be the first instance of ether inhalation for anaesthesia in this country. His attention was called last year to a remark by Mr. J. W. McDougall, secretary and treasurer of the Dumfries and Galloway Royal Infirmary, in an address to a rotary club, that "the infirmary was the first hospital in Europe to use general anaesthetics for its major operations, and that was before [the anaesthetic effect of] chloroform was discovered." Dr. Underwood thereupon wrote to Mr. McDougall, who replied that in the late autumn of 1846 Dr. William Fraser, a native of Dumfries, who was a ship surgeon, was visiting the infirmary while on leave, when a casualty with a fractured limb was brought in. The two surgeons of the infirmary, James McLauchlan and William Scott, asked Fraser to have a look at the case. Amputation being decided upon, Fraser, who had heard of the sulphuric ether discovery (probably from Morton of Boston, whom he knew) persuaded the surgeons to try it out on the case in question. By means of an apparatus hastily improvised, constructed by the three surgeons, the injured man was enabled to inhale a quantity of sulphuric ether vapour while the operation was performed in a painless and satisfactory manner. In a *Visitors' Guide to Dumfries* (1871) Dr. Underwood also found an account of this incident, and it was added that in 1868 Sir James Y. Simpson, speaking on the subject at a conversazione at the Royal College of Surgeons of Edinburgh, had mentioned

this fact and said that after the ether had been first used at Dumfries it was next employed by Mr. Liston, the eminent surgeon of London. This meant that the operation preceded that of Liston, that is to say, that it took place before Dec. 21, 1846. Mr. McDougal said the "late autumn," which implied a date in November. From a study of the hospital records of amputations it seemed that the operation must have been performed on or before Nov. 11, 1846.

NATIONAL INSTITUTE FOR THE DEAF

The National Institute for the Deaf had to close down a certain proportion of its activities during the war, but it is now contemplating a vigorous resumption, as was shown by the enthusiasm at its annual general meeting held in London. The DUKE OF MONTROSE (President of the Institute) said that in this first full year of peace they were determined to bring the cause of the deaf into the front line. It was estimated that there were in this country a million people deaf or with subnormal hearing. It was good news that as part of the National Health Service scheme a standard aural aid was to be provided for all which would be free of charge.

The Government's Proposed Hearing-aid

Lord WALKDEN (a member of H.M. Government) said that as a result of research by the Electric Acoustics Committee of the Medical Research Council an electric hearing-aid had been produced which had been accepted by the Government and was to form part of the provision under the scheme for a National Health Service. This would certainly be available in 1948, though he could not say in which month of that year. Both the instrument itself and the subsequent servicing would be available freely for all who needed it. The deaf would be enabled to have the benefit of consultations at special clinics in suitable centres, where experts would be able to say whether they could be helped by treatment; if they could be so helped the treatment would be afforded, again free of charge, and if not, the instrument would be provided. The outstanding difficulty in providing the instrument was to obtain suitable labour—the labour of the skilled instrument maker. The minute valves of the apparatus, much finer than those used in wireless sets, were difficult to produce and to maintain, but he was sanguine that full success would be achieved by the year after next.

Mr. R. SCOTT STEVENSON, who was warmly greeted as the new chairman of the executive committee of the Institute, said that he hoped the Government did not imagine that the problem of the deaf and the deafened would be solved by the provision of a universal hearing-aid. That was by no means the case. To begin with, there were many people to whom a valve amplifier would be of no value. In some types of deafness the simple ear trumpet was more successful than far more elaborate apparatus. There were many to whom no hearing-aid of any kind would be of use, and for them lip-reading and sign language was the only method of communication. Probably the greatest single need of the deaf in this country was not a hearing-aid but the provision of more teachers. Although the education of the deaf and dumb was now a statutory obligation, it was saddening that there should be only one school in existence for their higher education, and that that single grammar school should be attended by comparatively few children and should be in financial difficulties. The provision of hearing-aids, good as it was in itself, was not the end of the matter. He went on to pay a tribute to reputable hearing-aid manufacturers who had done a good job of work in this country, and he hoped the Government would not overlook the desirability of consulting with them in the production of their aid. If the Institute had only been able to get the component parts during the war it would itself have provided, through a group of hearing-aid manufacturers, a standard aid at a cost of not more than £10. The Institute was intending to reissue its list of approved hearing-aid manufacturers, but he explained that approval was limited to their ethical practice in selling and did not cover necessarily scientific approval of the aid. It was also hoped to set up a technical laboratory under the Institute's auspices for testing and repairs. In many quarters, again, there was a tendency to lay too much stress

on the size of the aid. No doubt smallness and inconspicuousness were useful characteristics, but efficiency outweighed them and he would rather have an aid the size of a portmanteau if it worked better. He wished to make it plain that those who had the interests of the deaf at heart were far from being ungrateful to the Government—which had done more for the deaf than any previous Government—but he begged them again not to take it for granted that the provision of a valve amplifier was all that needed to be done for the deaf.

Otology in a National Health Service

Lord LEVERHULME said that the Institute was fortunate in having secured Mr. Scott Stevenson as its new chairman. It was a happy coincidence that during his service in the R.A.M.C. Mr. Stevenson was billeted with the Duke of Montrose, who interested him in the work of the National Institute. They looked forward to a period of great vigour under his leadership. Lord Leverhulme also mentioned that Lord Cecil had put down an amendment to the National Health Service Bill in the House of Lords, the purport of which was that whatever was provided for an ophthalmic service should be also provided for an otological one. Other speakers included Mr. EDWIN EVANS, M.P., and Miss MARGARET RAWLINGS. A recent broadcast on behalf of the Institute by this accomplished actress brought in more than £2,500, to which was subsequently added a gift of £500 from the Goldsmiths' Company. The Institute, whose National Headquarters are at 105, Gower Street, London, W.C.1, has devoted £1,000 of the sum received to the training of qualified welfare workers for the deaf and dumb.

MEDICINE AND THE STATE

In the course of an address given in Liverpool Cathedral on Oct. 20 Sir ALFRED WEBB-JOHNSON, President of the Royal College of Surgeons, said:

For two things our hearts may well be troubled. One is lest the great administrative machine which is to be set up in connexion with the National Health Service may dim the high ideals of our profession, or mar the close relationship which should always exist between doctor and patient. The other cause for disquiet is lest scientific discoveries be used for man's hurt and ultimate destruction, instead of being devoted solely and entirely to his benefit and improvement.

It is the tradition of our calling that the poorest and humblest has just as great a claim on our services as the highest and most affluent. The measure of their need is the measure of the help which it is our duty and privilege to render. Thus it was that Sir Frederick Treves, when his Sovereign, King Edward VII, thanked him for his life-saving attentions, was able to reply with pride: "Sir, you have had as much care and skill in your illness as the humblest of your subjects." Such is the service that it is our privilege and duty to render, but we have been only too conscious of the limits of our ability—limits imposed by lack of adequate facilities. We have known that there were serious gaps in our service, and have realized that those gaps could only be filled with the help of the State. The State is about to take a great part in British Medicine. This is not surprising, for medicine is of wholly unique importance for the very existence of social life. But "As the master builder must care for the whole building—so he that undertaketh to set it out (and use it) must seek out all things for the adorning thereof." This will be our special and immediate task.

Some Essentials of Service

We must first ensure that the conditions of service are such as to allow intellectual freedom, and to give character as much chance as cleverness. We must avoid the development of Molière's type of doctor, who thought it more honourable to fail according to rule than to succeed by innovation. We must guard against uniformity, for the highest products of the human mind are the outcome of freedom and variety rather than of uniform organization. Independence, which inspires that fearless advice, must be preserved. In fact, if any of the essential freedoms of a great profession are threatened, then in the interests of the people, there must be revision of the plan. Even when a system has been formed there may still be much to add, to alter, and to reject.

The doctor's work is primarily a personal service, and his calling exacts the utmost that man can give—full knowledge, exquisite judgment, and skill of the highest, to be put forth, not at any self-chosen moment, but daily at the need of others. But illness is essentially a personal event. It consists of the individual himself. The patient is not limited by his outer covering. His surface is not his real frontier. A man may be more interested in his environment than in his own body. His position in the community or some work to which his passion drives him may appear to be of more importance than life itself. Thus it is that the family doctor has often to be his patient's confidant and friend. Then again, as Trotter said, "the well-equipped clinician must possess the qualities of the artist, the man of science, and the humanist, but he must exercise them only in so far as they subserve the getting well of the individual patient." He must feel directly responsible to his patient, not for him—to someone else. It is a hard doctrine, but none the less true, that this essential function of the doctor—the care of the given patient—may involve the foregoing of exactly scientific diagnosis, of the artistic perfecting of an operation, or even of the interests of society at large.

Dangers of a Comprehensive Plan

Those of us whose work lies in the hospitals must be prepared for changes under a new organization. We must see to it, however, that we carry into the national hospitals the same spirit which inspired us in the great voluntary hospitals. There we learned to scan gently our brother man—judging not, asking no questions, but meeting out to all alike a hospitality worthy of the Hôtel Dieu, and deeming ourselves honoured in being allowed to act as its dispensers. We must keep the souls and individuality of our hospitals alive, for hospitals are human institutions. No rigid plan, without margin or elasticity, will suffice or succeed. Above all, the State must not try to control development too strictly, for hospitals are also scientific institutions, and the essence of science is change.

We know the dangers of a great comprehensive plan for a National Health Service. We must guard against them—and it is right and fitting that we should gather in this holy place on the occasion of the Festival of Saint Luke, the Beloved Physician, to dedicate ourselves anew to the high ideals of our calling.

Application of Scientific Discoveries

But medicine is a science as well as an art, and we are vitally concerned with the application of scientific discoveries for the benefit of mankind. In our own time inventions and developments have followed each other fast as falling leaves, and the great blessing is that the leaves from the tree of science have been largely for the healing of the people. Advances have been achieved by the method of experiment—the method which, beyond all shadow of doubt, is the most effective implement for the advancement of knowledge ever invented by man. Moreover, it satisfies man's inveterate instinct not to confide his weight to a branch until he has tested it.

The greatest discovery in modern medicine is the detection of the minute bodies which cause many diseases, and the means by which they are carried. Pasteur, Lister, and Manson are the rocks upon which the whole structure of our modern knowledge is built. They were men of humble piety and devout Christianity. So also was Ronald Ross, to whom belongs the honour of the actual detection of the mosquito as the carrier of the malaria parasite. We have but lately realized that we may be able to control or destroy these winged vectors of disease. Millions on millions of lives could be saved and the morale of native peoples raised by the prevention of malaria alone. The millions that are saved must be fed. They must be reckoned with. This will be a problem for future generations: our task and duty are clear. As Carlyle wrote: "Let a man do his work; the fruit of it is in the care of Another than he." And do we not read in the Book of Wisdom: "Glorious is the fruit of good labours"? But let us also heed these words of Carlyle: "Man, 'Symbol of eternity imprisoned into time,' it is not thy works, which are all mortal, infinitely little, and the greatest no greater than the least, but only the spirit that thou workest in, that can have worth or continuance."

That is the point—the spirit that thou workest in. Scientific discoveries are powers for evil as well as for good. Is it not time that we decided that their use for the wholesale and

indiscriminate destruction of human life should be outlawed? It is not only physical and chemical knowledge that can be misapplied. It has even been suggested that biological discoveries might be used for bacterial warfare. Is it not more in accord with our traditions and ideals to follow the example of Jenner, who when England and France were at war sent Woodville to Paris to help to control an epidemic of smallpox which was raging in the French capital? To commemorate this humanitarian action there stands at Boulogne to-day a statue to Jenner inscribed: "A Edward Jenner—La France Reconnaissante."

It may be that man is at the cross-roads. Will he proceed higher and further, or will he bring about the catastrophic ending of the whole human story? It is for man to decide his own fate.

Geographical Distribution of Disseminated Sclerosis: A Request for Information

SIR,—Disseminated sclerosis is well known to be common in some countries (e.g., Switzerland) and very rare in others (e.g., South Africa). Its incidence varies also in different parts of a country, for it is more common in North than in South Switzerland. Investigations at present being carried out indicate that disseminated sclerosis is relatively common in England, and that patients suffering from the disease number two to four per 10,000 population. There seem, however, to be certain parts of the country where it is much more common than this, and others in which it is rarely if ever seen. Information regarding its geographical distribution is being collected here for research purposes, and if any doctor can give information regarding the local incidence of disseminated sclerosis or has been impressed by its frequency or rarity in his district, we should be grateful if he would communicate with us. Areas of the country where the disease does not occur are just as important as those in which it is frequent.—I am, etc.,

Radcliffe Infirmary (Neurology), Oxford.

W. RITCHIE RUSSELL.

Errors in Regard to Goitre

SIR,—My attention has been drawn to a paper by Linnell, Keynes, and Piercy (Sept. 28, p. 449) appropriately entitled "Some Vulgar Errors in Regard to Goitre." I propose to confine myself to a criticism of paragraph IV, headed in fact correctly, "That no goitre should be considered toxic unless the basal metabolic rate is found to be above normal."

Let us deal first with the measurement of the basal metabolism. It is a relatively simple technique if it is done in the right way, but it has many pitfalls for the uninitiated. Du Bois (1936) has written an excellent monograph on the subject, and more recently (1944) I recapitulated certain essential criteria for obtaining an accurate and reproducible result on in-patients and out-patients. Using such well-known normal standards as those of Aub-Du Bois or Harris-Benedict, the range for normal people in England is 0 to minus 21. It is important not to confuse, as is so frequently done, a reading that is "within normal limits" with a reading that is "normal" for the individual. For example, I have seen a case of thyrotoxicosis with an initial basal metabolism of minus 8 which is "within normal limits," but that reading was raised above the patient's own "normal," which was in the region of minus 21 (1934).

It is wrong to say that a subject's basal metabolism can give "very different readings on two successive days." There must be something very far wrong with the technique employed if such results are obtained. Facilities rather than finance are of course very necessary pre-requisites for obtaining accurate results, and obviously these vary from clinic to clinic. At the Middlesex Hospital I have found no such difficulty in a study of over 2,000 normal healthy subjects, and in examining over 6,000 cases of thyrotoxicosis referred to the Courtauld Institute of Biochemistry, the Middlesex Hospital, from that hospital and from other similar institutions.

Next let us study the action of iodine on the basal metabolism in thyrotoxicosis. To begin with, it must be appreciated that iodine has no effect whatsoever on the basal metabolism.

of normal healthy people. But iodine has a specific action in lowering the basal metabolism in a case of active thyrotoxicosis—very rarely it may cause the basal rate to rise. Not only pure iodine itself but all its soluble compounds have a similar action if the dose exceeds 6 mg. of iodine daily, or the equivalent of approximately 1 min. (0.06 ml.) of Lugol's solution. If, therefore, the thyrotoxicosis is active, iodine will certainly alter significantly the basal rate. In the case I reported with an initial reading of minus 8, iodine reduced the basal rate to the region of minus 21. Even if the thyrotoxicosis is minimal iodine will produce such an effect. While not making any comments on alterations in the general metabolism in thyrotoxicosis (there is, however, an ample literature on impairment of calcium, carbohydrate, creatine, and iodine) it can be stated that the basal metabolism is certainly affected and is significantly altered. I had the privilege on many occasions of discussing the metabolic aspects of thyrotoxicosis with my good friend the late Mr. Cecil Joll. He, keen critic as he was, on no occasion referred to the measurement of the basal metabolism as a "poor test." On the contrary, he expressed in a letter quite the opposite view (1934).

The use of thiouracil in lowering the basal metabolism as a diagnostic test in doubtful cases of thyrotoxicosis is of course of doubtful value. Thiouracil will cause a normal basal metabolism to fall even to a myxoedematous level, acting as it does in inhibiting the formation of thyroxine at the site of its synthesis, the thyroid gland. Iodine on the other hand is the only drug that has a specific action first in affecting the raised basal rate in thyrotoxicosis, secondly in having no effect on a normal basal rate.

In summary, it may be said that measurement of the basal metabolism requires care, careful technique, the employment of controls, alcohol-checked apparatuses, patience, and an awareness that its determination presents many pitfalls to the unskilled operator. My visit to America has impressed me, among many other things, with the care and accuracy with which this determination is carried out and also with reports made on the results obtained.—I am, etc.,

London, W.1.

SIR.—I feel that in their article Dr. J. W. Linnell, Mr. Geoffrey Keynes, and Mr. J. E. Piercy (Sept. 28, p. 449) have grossly overestimated the frequency of thyrotoxicosis as a cause of auricular fibrillation when they state that "it is not yet generally appreciated that next to acute rheumatism toxic goitre is the most fruitful cause of auricular fibrillation."

In an analysis of 575 cases of auricular fibrillation published in 1932 by McEachern and Baker (*American Journal of Medical Science*) thyrotoxicosis accounted for 7.5% of cases, rheumatic heart disease for 34.4%, coronary artery disease for 31.1%, and hypertension for 16.9%; emphysema, syphilis, and miscellaneous conditions accounted for the rest. Four years earlier a series of 376 cases of auricular fibrillation was published by White and Jones, and thyrotoxicosis, as the aetiological agent, was found in 4.0% of cases, ranking fourth on the list. One has only to recollect the frequency in which one sees auricular fibrillation in obese and stolid individuals over the age of fifty to be sceptical of the importance of toxic goitre as the cause in the large majority.

Could it be that the now fashionable disregard for the B.M.R. has made a diagnosis of "early thyrotoxicosis" so frequent and often, in my opinion, so unjustifiable?—I am, etc.,

Liverpool.

C. M. MILLER.

SIR.—The article on "Some Vulgar Errors in Regard to Goitre" (Sept. 28, p. 449) is deeply interesting and worthy of very close study; and the part dealing with thyrotoxicosis suggests questions to which it would be helpful to have answers. One sentence caused me some apprehension: "We, for our part, believe with Hertzler and many other workers in different parts of the world, that by the time early

middle life is reached goitres without some evidence of associated toxicity are rare." Such goitres are in my experience much more common in women, and the signs and symptoms of mild toxicity are exactly those that may be present in women of that age who have no goitre.

Then again the less gross and less easily discernible signs and symptoms of thyrotoxicosis at any age are those which different clinical conditions may show, and in some of these the resting and, I believe, even the sleeping pulse rate may be raised. Given these signs and symptoms, should one recommend a subtotal thyroidectomy to preclude the possible onset of an auricular fibrillation?—and these are signs and symptoms the interpretation of which must be a matter of personal opinion. That auricular fibrillation may be the result of, or associated with, thyrotoxicosis is undoubted, but in my experience, which may differ from that of others, the fibrillation occurring in a case of mitral stenosis or acute rheumatism is already established, at least at the time one sees the case; and if that statement be accurate, then the position of paroxysmal auricular fibrillation in regard to thyrotoxicosis becomes interesting indeed. Again, "the fact that there may be phases of exacerbation and intermission of the symptoms does not make their discovery easier." It certainly does not, and this statement also applies to the other conditions which give precisely similar symptoms. Moreover, it has occurred that a goitre has appeared accompanied by the milder symptoms of toxicity as a result of emotional stress, and symptoms and goitre disappear, to reappear a few years later on the occasion of another emotional strain.

All these considerations increase the burden of responsibility on the doctor who has to decide what treatment is advisable in a case where the exact diagnosis must be a matter of conjecture; and the mortality even in the hands of expert surgeons is still 1%. I agree that the above types of cases provide the least operative risk; and although the operation by experienced surgeons in undoubted cases of thyrotoxicosis gives extremely satisfactory, even superlatively good, results, there are cases, also equally expertly operated on, where the immediate or final results are not so comforting to the patients or their doctor.—I am, etc.,

London, E.2.

L. J. MOIR.

Catheter and Prostate

SIR.—Mr. C. J. A. Woodside asks (Aug. 31, p. 309) what should be done for the patient suffering from acute upon chronic retention from prostatic obstruction. The answer is that morphine and the suprapubic insertion of an aseptic lumbar puncture needle attached by a sterile rubber tube led into a sterile bottle will permit comfortable and safe transport for 100 or 200 miles. This is less painful than catheterization and does no damage to the delicate urethra (June 29, p. 997). Such a needle has been left in the bladder for three days, but in the presence of pyuria this would be a dangerous procedure. If a catheter has "perforce" been passed, then an immediate prostatectomy with closure of the bladder with unusually intensive chemotherapy and sepsis should be carried out forthwith. Mr. Morton Whitby failed in his attempt to close the bladder (*Lancet*, 1934, 1, 81) because of his want of asepsis and omission of trigonectomy, which is an essential part of my operation. Perhaps my introduction of sodium citrate would have made his operation possible. In my last 700 cases there has been one postoperative clot retention necessitating opening of the bladder. The clot was removed but no bleeding point of the bladder. The clot was removed but no bleeding point found, and the bladder was then resutured. When I meet my next clot retention, having stopped the bleeding I shall again close the bladder in order to avoid sepsis. For six years I have not done a suprapubic drainage and never expect to do another.—I am, etc.,

Manchester.

WILSON H. HEY.

Amniotic Membrane for Corneal Grafting

SIR.—Blindness from trachoma in China is a very prevalent condition, and in my role of surgeon to seven Honanese hospitals I have seen a distressing number of these cases. Corneal grafting by the accepted method is out of the question in China for various reasons related to the veneration people have for deceased relatives.

Macrocytic Anaemias

'Heparglandol'-B 2c.c. Ampoules issued by Roche present a potent, injectable liver extract fortified with the following important factors of the B complex:

Aneurine (Vitamin B ₁)	3.0 mg.
Riboflavine (Vitamin B ₂)	1.2 mg.
Nicotinamide	20.0 mg.
Pyridoxine (Vitamin B ₆)	1.0 mg.
Pantothenic acid	3.0 mg.

In addition, the preparation contains the active extract of 20 gm. fresh liver, including vitamin B complex naturally present in liver.

'HEPARGLANDOL'-B

FORTIFIED LIVER EXTRACT
INJECTABLE VITAMIN B COMPLEX

Boxes of 6 and 12 Ampoules

ROCHE PRODUCTS LIMITED

Welwyn Garden City, Herts.

Scottish Depot: 665 Great Western Road, Glasgow, W.2.

New 'EPHYNAL' Vitamin E Preparations

10 mg. Tablets containing alpha-Tocopheryl Acetate.
30 mg. Ampoules containing alpha-Tocopheryl (in oil).
'Ephynal' is now obtainable in Tablets of 3 mg., 10 mg. and 20 mg. and in Ampoules, 30 mg.

Further information and samples of tablets on application.

THE MENOPAUSAL SYNDROME

MENOPAX

ANTI-PRURITIC CREAM

In this preparation the causal effect of stilboestrol is combined with potent analgesics producing prompt and prolonged local anaesthesia, thus achieving a double purpose; it stops the irritation, soothes and heals the excoriated surfaces, and provides for a more normal nutrition of the tissues by augmenting the deficient local supply of oestrogen.

Menopax Antipruritic Cream is of proven clinical value in pruritus and kraurosis vulvae, senile pruritus, vaginal ulceration, early cases of leucoplakia vulvae, etc. Pruritus ani and haemorrhoids in both sexes are equally benefited to a remarkable extent.

Amethocaine	0.5%
Benzocaine	5.0%
Diethylstilboestrol	0.1%
Camphor	2.0%
Zinc Oxide	5.0%
Terpinol	1.0%

Clinical samples and literature will be gladly sent on request.

SURREY.

MORYL
TRADE MARK BRAND

CARBACHOL

Parasympathetic Stimulant

A powerful stimulant of the parasympathetic nervous system, chemically related to acetylcholine, but more active and more stable.

Indicated more especially in post-operative intestinal stasis and urinary retention, "Moryl" is also useful in eclampsia and pre-eclamptic conditions, hypertonia, paroxysmal tachycardia, anxiety neurosis, ozaena, and glaucoma.

In ampoules, oral tablets, and special solutions for glaucoma and ozaena.

TETRONOX
TRADE MARK TABLETS BRAND

Hypnotic—Sedative

Formula: Each 9 gr. tablet contains w/w Barbitone B.P. 80.7%, Phenazone 5.5%, Phenacetin 5.5%, Hexamine 1.1%, Magnesium Peroxide 0.9%, Excipient to 100%.

Enhanced power of barbitone through careful combination with other drugs—reduced toxicity; no cumulative action or injurious effects on circulation, respiration, or gastro-intestinal tract.

The Dietary during The Age of Growth

AT no time, throughout the span of life, is the proper and orderly balance of the important food factors more readily disturbed than during the period of active growth and development.

The food supply of every child should, therefore, contain an adequate proportion of essential nutritive elements if normal progress is to be maintained. The construction of an entirely correct dietary, to suit the varying requirements of each individual, is, however, beyond the possibility of realisation in ordinary practice.

Many physicians ensure that the ordinary dietary of the young patient is safe and adequate by advocating the daily addition of "Ovaltine," which is a natural food tonic prepared from milk, eggs, and malt extract, with a cocoa flavouring. The deliciousness of "Ovaltine" makes it most acceptable to every child, while it is readily assimilable even by digestions impaired with disease.

The 'only' treatment for LUPUS VULGARIS

Oral administration of vitamin D is virtually the only treatment today for lupus vulgaris, and recently very good responses have been obtained in a series of cases with doses of 50,000 to 150,000 i.u. daily.*

High dosage of vitamin D has been given successfully in a variety of other diseases, such as rickets and arthritis, but never apparently before in lupus. Most patients will tolerate these doses very well. Toxic symptoms, when they occur are usually mild.

High-potency 'Ostelin' Capsules (100,000 i.u. each) are convenient and contain the pure crystalline vitamin D₂. They are thus free from the side products of irradiated ergosterol to which certain toxic effects are attributed.

*Proc. Roy. Soc., Med., (1945) 39, 46

CHLOROFORM

SIR JAMES YOUNG SIMPSON

OUR association with the manufacture of Chloroform dates back to 1847, when Sir James Young Simpson demonstrated its anaesthetic properties and approached Dr. Thomas Smith (Founder of our Firm) with a view to obtaining sufficient quantities to carry out his pioneer work.

Our long experience enables us to produce an anaesthetic chloroform of standard composition, UNSURPASSED FOR RELIABILITY, and answering the tests of all pharmacopoeias.

BLANDFIELD CHEMICAL WORKS • EDINBURGH

AND AT
LONDON &
GLASGOW

Although I had no special knowledge of ophthalmology, his problem had obtruded itself so strongly that I was impelled to try the grafting of amniotic membrane. Amniotic membrane, after treatment, is fairly transparent and when laid on the cocaineized eye it was found that the individual bricks could be counted on a wall at a distance of thirty feet. It was felt too that if the grafting should succeed tissue metaplasia might reasonably be expected to take place.

A totally blind beggar volunteered for the experiment. He had a chronic infection of the eyelids from trachoma, which had caused his blindness. After three days a graft of his left eye had taken soundly and his anterior chamber was filling out. He could distinguish light. Shortly afterwards he could see objects, and on the seventh day he could count fingers at two feet; on the ninth day he could eat his meals with chopsticks; on the tenth day he had two small ulcer-like areas below the pupil and could not see so well. Instillation of penicillin was tried and two days later (almost at the time of writing) he had an improvement of vision. A good result from this case can hardly be hoped for as the patient's eyelids were already grossly infected.

At the same time two further grafts were done on two people with no infection and unilateral blindness. The result of these cases is now awaited and will be reported on later. In the meantime it is evident that amniotic membrane is a suitable tissue for use in corneal grafting.—I am, etc.,

WILLIAM J. C. WELLS.

Shanghai.

Abacterial Pyuria Presenting as Urethritis

SIR,—I read Capt. A. B. Fieldsend's interesting article on the above subject (Oct. 5, p. 493) and should like to make a few suggestions:

(1) Three cases of abacterial pyuria are described without any reference to the condition of the kidneys. Surely, to most urologists, sterile urine containing pus cells is so strongly suggestive of an acid-fast infection that they will not accept any other diagnosis until this has been excluded? A tuberculous urethritis is admittedly rare, but it is described by Continental urologists as being a not infrequent accompaniment of a tuberculous infection of prostate or vesicles. (2) Inability to find the gonococcus and a negative complement-fixation test lead your correspondent to discard a diagnosis of gonorrhoea. Is this justified? My experience of gonorrhoea in this country is small, but when serving in West Africa one had to deal with gonorrhoea in numbers quite unparalleled at home. The two most striking features out there were the extreme difficulty in curing Europeans infected by African women and the difficulty in those cases of demonstrating the gonococcus unless the cases were seen right at the start, and before any treatment had been given. That they all were gonococcal and not "non-specific" was shown by the fact that smears were always taken daily, and every now and then a few gonococci would make their appearance—seldom intracellular even then. I so vividly remember an unfortunate young medical officer who came to me from up-country in despair at having failed to cure himself. I turned on all my guns, including all the usual methods except penicillin, which was not available, but had to confess defeat and passed him further "down the line." They were no more successful, and at the end of six months the poor chap was boarded home in the hopes, I suppose, that a change in climate might have some effect. (3) Finally, with regard to the third case, surely a gonococcal cystitis is not very uncommon? Certainly, where the West African is concerned, a simple urethral discharge is regarded with such little concern that it is often only a severe cystitis which drives him to seek medical attention. As he has probably already taken some black market sulphonamide tablets (sold in the market at 5s. each) the elusive gonococcus may never be captured.—I am, etc.,

Ashford, Middx.

R. T. BURKITT.

Benign Tertian Malaria in England

SIR,—The following two cases of benign tertian malaria are considered of interest as both occurred in subjects who have never been abroad. In both cases it is believed that infection occurred in Oxford.

The first, a girl of seventeen, suffered from intermittent daily pyrexia from Aug. 26 until antimalarial treatment was started on

Sept. 26, after a blood film had shown B.T. trophozoites. After an indefinite onset with general malaise, lassitude, and headache, she complained each afternoon of chills and shivering followed by heat and sweating, the whole cycle lasting several hours. Headaches were her main complaint. The highest recorded temperature was 105° F. (40.6° C.). There was a partial remission of symptoms for several days in mid-September. Agglutination tests were negative for typhoid, paratyphoid, and undulant fever, and a chest skiagram showed no abnormalities. On Sept. 3 her spleen was just palpable. Her symptoms were promptly and completely relieved by quinine. Her brother had a relapse of B.T. malaria, confirmed by positive blood films, while on leave from Burma in April last. He was treated at home for a week before being sent back to his unit. Following demobilization he has lived at home since June 3, but has had no further symptoms. The second case was a railway worker aged 47 who has left Oxford only once in the past nine years. His symptoms of fever occurred each night from about Sept. 15 until antimalarial treatment was begun on Oct. 1, following a positive blood film. At the time of onset he was convalescent from an attack of pneumonia which began on Aug. 28. In this case headaches were absent.

These two patients live within sixty yards of each other and close to a slow-flowing branch of the Thames.—We are, etc.,

Delete "Curarine"

SIR,—One must regret that both Drs. T. Cecil Gray and John Halton in their interesting description of their method of using *d*-tubocurarine chloride "as an integral part of anaesthetic procedure" (Aug. 31, p. 293), and Dr. C. Langton Hewer in a more recent reference (Oct. 12, p. 531), so quickly relapse into the misnomer "curarine" for the curare preparation which they used. The confusion which has arisen because "curarine" once meant one thing and is now in danger of meaning a number of other things, and the desirability that the term, used without prefix, should therefore be dropped, has already been the subject of a letter from Dr. Trevan of the Wellcome Research Institute (*Lancet*, Sept. 7, p. 361). The makers of the preparation which Drs. Gray and Halton were using, and whose former nomenclature they followed, have now rechristened their preparation "tubarine" in order to meet the needs of doctors who feel "*d*-tubocurarine chloride" to be too long a name for repeated use. We must expect other preparations of curares and drugs with curariform actions to appear on the market. They also will probably carry long names for accuracy and short names for convenience. They will not all have the same total pharmacological action, however, nor will they be of the same strengths. And, unless we are going both to continue confusion and make nonsense of much of the work which was done on these alkaloids in earlier days, we must avoid reducing any of these titles to plain "curarine."

For years the term "curarine" was applied to an impure alkaloid variously obtained from calabash curare and *Strychnos toxifera*. It had better now be regarded as a term of historical interest only.—I am, etc.,

Edinburgh.

RANYARD WEST.

The Referendum

SIR,—The B.M.A., it is understood, will take a referendum, as soon as the National Health Service Bill passes through the House of Lords, asking its members whether they wish negotiations opened with the Minister of Health on the terms of service in the new scheme. As we have no reason to believe that "negotiations" will achieve anything unless there is a definite threat to this Bill's very existence, it would seem obvious that there is only one course of action open to us when we make our answer. Given a Minister who shows more respect for age-old traditions of service and a more compromising attitude one would feel very differently about opposing outright a Bill which has cost so much in time and human endeavour.

If we as a profession genuinely believe that this Bill will bring about the enslavement of both the individual doctor and his patient, to the detriment of both, and that drastic changes in certain vital respects are necessary to remedy these defects, we should answer NO with all the strength and faith that is within us. Genuine negotiations can then follow, and not till then, and the results will be fruitful. Let us realize that the Minister is a man experienced in the methods of industrial

dispute, where both sides come to the conference table possessed of considerable bargaining power. Surely it is the Minister's belief or hope that the doctors are so divided that has led him to override all opposition in a way which suggests his contempt for the medical profession as a force to be contended with.

Those of us who feel that their future might be jeopardized by opposing this Bill by means of the referendum can reflect that they are merely expressing an honest opinion. In the event of a 90% vote against the Bill they will place in the hands of our leaders a weapon which will enable them to fight this battle to a satisfactory conclusion.—We are, etc.,

The Milk Ration.

SIR,—I am sure many practitioners will be grateful to Mr. A. Staveley Gough for his letter (Oct. 12, p. 551) on the milk ration. A vicious circle is now well established. As the milk ration sinks the pressure on the doctor to place ailing patients in one or another favoured category rises; none of those entitled goes a single day without his or her full extra allowance; the priority pool swells, the non-priority puddle dwindles; the decent, honest, healthy citizen feels—and is—ill-used, the doctor is riled. Surely it is time to break this circle somewhere.

I suggest that for many of the categories the allowance might be halved without undue hardship. One pint a day for ulcer patients not in bed, for post-operative conditions, and perhaps for tuberculosis, and half a pint for temporary illness, the sick child at home, "dyspepsia"—blessed word—and perhaps colitis ought to be enough. Probably not even the Minister knows precisely how the nation's milk is distributed between the different categories, but it seems a fair guess that such a halving would permit the ordinary ration to be appreciably raised and reduce a little the unceasing demand for priorities.

At the same time the Minister might declare a countervailing bounty for persons over 75 and revise that ominous category I (g) which forbids any medical man under the rank of tuberculosis officer to provide any extra milk at all for a patient with a pleural effusion.—I am, etc.,

London, N.W.3.

LINDSEY W. BATTEN.

Selection of Medical Students

SIR,—The correspondence in the *Journal* of Oct. 5 suggests that the problem of selection of medical students may call for a knowledge of techniques not possessed by the amateur selector. Although I had already realized this it none the less seemed to me important to make a detailed presentation of the case from the amateur point of view, since in fact selection of medical students in this country is carried out mostly by teachers, and professional selectors rarely have an opportunity using their skill in choosing medical students. This is not intended as an apology for the amateur nor a slight for the professional, but merely a statement of the present position. (I use the words amateur and professional in their relation to technique of selection.) Having put forward the amateur's point of view I very much welcome the criticisms of the professional, but I should like to make some comments on these.

Dr. D. R. MacCalman (p. 511) informs me that the Army psychologists in 1941 took up the problem where I left off. I actually knew that the technique of selection had been highly developed in the Services and stated so in my article, but I also stated that until the information obtained was made available the knowledge of its existence was of little immediate help. I am grateful for the hints which Dr. MacCalman gives about the general nature of the work in the Services, but I should welcome still more details of the methods used, and the suggestion made by Mr. Slater that the War Office might be invited to publish this information is an excellent one. Dr. MacCalman suggests that testing for a general capacity of "officer effectiveness" is much better than looking for individual qualities. Perhaps he could suggest how this can be applied to selection of medical students. Is there a quality of "doctor effectiveness" which can be assessed, and if so,

how can this be done? I am very interested to learn of the research which is being carried out at Aberdeen, and I hope the results will be made available as soon as possible. I am afraid I did not make quite clear my attitude towards participation of psychologists in selection of medical students. After pointing out that there was sometimes a feeling of alarm at the idea of psychologists selecting medical students I went on to give reasons why this fear was probably groundless, though I am sure it is true to say that the feeling exists. I can certainly assure Dr. MacCalman that I personally feel no alarm about this matter, as I am sure that the way to success must lie in full co-operation between the well-meaning amateur who at present has the executive responsibility for recruitment to the medical profession and the well-trained professional who has the necessary techniques.

Mr. Patrick Slater (p. 512) has questioned my conclusions about the negative value of interest in selection. I stated that an interest in medicine expressed by an applicant has little selection value, and I still hold to this opinion. The candidate's general interests are, of course, something quite different and, as Mr. Slater points out, one of the means of judging character. I cannot agree with his contention that the most economical method of selection is to choose at each stage those who have the highest probability of succeeding at the next. It implies that the basis of selection should be ability to pass the examinations of the medical curriculum, or, to push the argument further, to pass the first M.B. examination. I should very much like to know from Mr. Slater what criteria have been used at the National Institute of Industrial Psychology in giving prospective medical students advice about their suitability for a medical career. If reliable methods have been worked out they should certainly be made available. Finally I agree very fully with the view expressed in your leading article, that selection of the applicants is only the beginning of the problem and should logically be followed by guidance during the period of training, so that the talents of the individual might later be used to the fullest advantage in one of the many fields of work offered by modern medicine.—I am, etc.,

University College, London.

D. H. SMYTH.

SIR,—Mr. J. S. Wilkie, in his article on the Selection of Women Medical Students (Sept. 14, p. 367), makes a great many statements—and an even greater number of implicit assumptions—which would appear unwarranted to psychologists used to applying the scientific method to problems of vocational selection. To deal with every controversial point in the article would take up too much of your space. May I concentrate, therefore, on the more surprising points?

(1) All Mr. Wilkie's elaborate statistical calculations are concerned with the relationship between individual questions, or groups of questions, and the total test score. Little of value can be deduced from these relations unless data are given on the validity of the test as a whole—i.e., on the relationship between total test score and students' proficiency (assessed independently of the test). Mr. Wilkie deduces, for instance, that the second part of his test (sub-questions to which the answer can be given in one word) is as reliable as the first (questions to be answered by continuous passages of prose), because the two parts correlate roughly to the same extent with question No. 10, or it may be because the average correlation of questions Nos. 6-10 with the total is significantly higher than the average correlation of questions Nos. 1-5 with the total. Mr. Wilkie's reasoning on this point is not clear to the writer, but it is evident that no data are given which throw any light on the relative validity of the two parts of the test. (2) The finding of the higher correlation with the total of questions Nos. 6-10 may well be an artefact of the scoring systems. If, in general, questions Nos. 1-5 show less range of scores than questions Nos. 6-10 (Nos. 1-5 having smaller variance), then the difference between the correlations which were obtained is to be expected on purely arithmetical grounds. The data for this explanation are not given, but in view of Mr. Wilkie's description of the marking of the two sets of questions it would appear highly probable that this is in fact the case. (3) Mr. Wilkie infers that question No. 10 is a "test of intelligence" from the fact that the 118 first-year candidates do not score significantly less than the 258 second-year candidates. Apart from the fact that he adduces no evidence to prove that these two groups are

comparable (he even mentions that "it is not difficult to think of circumstances which might have had a prejudicial effect on some of the studies of the older group"), the following objections present themselves: (a) No one question can constitute "a test of intelligence." A number of questions embodying a variety of logical principles is essential. (b) The assumption that any question in which the first-year candidates do at least as well as the second-year ones is *for that reason* a measure of intelligence leads to the most absurd conclusions. On this criterion, a question as to the relative merits of two film stars or the best method of baking bread would almost certainly turn out to be a test of intelligence. (c) Mr. Wilkie tacitly admits the improbability of question No. 10 being a test of intelligence when he says that "it might also be a test of self-confidence." The same question cannot assess both intelligence and self-confidence (or any other temperament trait) unless they are identical or are always found together. Neither doctors nor psychologists would assert that the most self-confident people are in fact the most intelligent. That the former trait is "not an undesirable quality in a medical student" is irrelevant here. All that can legitimately be said on the question of the relative proficiency of first- and second-year candidates is that if the second-year do significantly *better* on some test, and *other things are equal*, then the test is probably *not* assessing intelligence. (4) Mr. Wilkie evidently believes that armchair inspection of any test question is sufficient to determine whether "whatever it tests is an ability or a group of abilities which would be desirable in a student of medicine." Apart from the fact that little agreement has been reached by the medical profession as to the qualities necessary and sufficient for medical competence (see Dr. Smyth's comprehensive inventory of human virtues, Sept. 14, p. 360), there is no short-cut method of determining what it is that a psychological test assesses, let alone what one particular question assesses. This can be done only by testing large numbers of people, following them up (whatever their test performance) and comparing their success or failure in their career with their original test scores. (5) Apart from criticism of the test questions, the system of marking was such as to render inter-question correlations meaningless. Some of the questions, such as No. 2 ("concerning methods of teaching two school subjects") were necessarily highly subjective in their marking.

The second part of the test is described as capable of being "marked with much greater ease and reliability than the first part." The first five questions have been arbitrarily "translated into numerical form" and these marks have been compared with the marks allotted on the remaining questions. This is not statistically permissible.

The writer has no quarrel with Mr. Wilkie's final conclusion—that a test designed to be objectively marked is as reliable for selection purposes as a test with the same function whose marking is subjective. She would claim, however, that it is possible to reach that conclusion only by means of tests whose consistency and validity have already been established. Finally, she would suggest that vocational selection might be treated with the respect accorded to other technical problems—i.e., long-term experiments should be planned, reliable criteria should be provided for purposes of comparison, and the co-operation of the relevant experts should be enlisted.—I am, etc.,

Psychological Laboratory, Cambridge. A. W. HEIM, M.A., Ph.D.

Legal and Medical "Insanity"

SIR,—Admitted imperfections in the McNaghten Rules are unlikely to be corrected by the type of pseudo-scientific casuistry displayed by Dr. J. A. McCluskie (Oct. 12, p. 555) when he questions the meaning of the words *right* and *wrong*. Nor is it possible to extract from his letter one single constructive proposal for the improvement of judicial procedure in the type of case under discussion. In fact, such procedure would inevitably be even more unsatisfactory than it is at present were his assumption as to the purposelessness of these fundamental terms valid. Where there is no conception of absolute values there can be no justice. The essence of the present legal view is surely that a man is either responsible or certifiable: to the lay mind this has the merits of logic, justice, and simplicity. If it is right, the first task of the psychiatrist in helping to improve upon the existing rules will be to define the place of

the psychopath in this proposition. If it is wrong, he must be prepared to suggest a better alternative. But if such distinctions have little or no meaning for him, it is hard to see how he in his turn can accept this responsibility.—I am, etc.,

London, S.E.5.

D. STAFFORD-CLARK.

Perforation of the Ileum in Enteric Fever

SIR,—Dr. G. E. Dunkerley in his article "Perforation of the Ileum in Enteric Fever" (Sept. 28, p. 454) has made an important contribution to this interesting subject, of which on two occasions during the last two years I have had experience.

Perforation in my first patient occurred on the twelfth day, without previous diarrhoea or distension, and was not diagnosed as such until eleven hours after the event, when peritonitis was established. The single perforation 1 ft. (30 cm.) from the ileo-caecal valve was closed and the pelvis drained. The post-operative course was uneventful by bloodstained pleural effusion, pelvic abscess, obstruction by bands, myocarditis, a mild heat stroke, and a ventral hernia; but the patient recovered.

The second patient suffered from severe diarrhoea and distension but had been on succinyl sulphathiazole therapy for 24 hours before perforation occurred on the thirteenth day. I saw him within a quarter of an hour of a sudden attack of right-sided abdominal pain, but perforation did not seem to be a certainty. He was lying quietly in bed; the temperature was 101° F. (38.3° C.) and pulse rate 110. The abdomen was not rigid, but there was tenderness in the right iliac fossa. Gut sounds were audible with a stethoscope. Two hours later the pulse rate had risen to 120 and the temperature to 105° F. (40.6° C.), and a rigor occurred. The abdomen was now rigid and tender all over, and gut sounds and liver dullness were absent. At operation (2½ hours after the attack of severe pain), a single perforation 1½ ft. (45 cm.) from the ileo-caecal valve was found and was sutured. Convalescence was even more stormy than in the first case. Gastric suction and continuous intravenous infusion were given almost continuously for 40 days. Complications in this case were: secondary haemorrhage from the right deep epigastric artery (which required ligaturing), obstruction of the small intestine by bands followed by herniation of a loop of jejunum through the wound (treated by resuture of the main wound and enterostomy through a separate stab incision), and later there followed symptoms of tetany, myocarditis, and finally a left-sided empyema (drained surgically by Major I. P. James); but again the patient recovered.

These two case histories support Dr. Dunkerley's thesis that perforation usually occurs earlier than in the third week and the classical signs of perforation may be absent in the early stages. The prognosis is also better than is generally supposed, because nowadays we are able to treat the associated serious derangements of the blood chemistry. The typhoid patient requires plenty of fluid and a high protein diet administered by three-hourly feeds, and often, when the action of the damaged bowel flags, timely parenteral substitution is necessary to keep the patient alive.—I am, etc.,

Leeds.

MICHAEL C. OLDFIELD.

Postgraduate Education

SIR,—I feel compelled to express my approval of every detail of Mr. John Stallworthy's well-reasoned letter (Oct. 5, p. 510). It is high time that practical clinical medicine and surgery should be granted the importance overdue to them. It is the practising physician or surgeon who applies the good results of research undertaken by his more academically minded colleagues—the professor and the research worker. In the past, however, clinical workers themselves have made most important contributions to clinical research. This is often forgotten. The Postgraduate Federation outlined by Sir Francis Fraser must of necessity foster the academic aspect to the detriment of the practical and clinical. It appears to me that a unique opportunity presents itself in London to place medical teaching on a sound basis. It has been suggested that all undergraduate teaching should be based on the University and that the three Royal Colleges should organize postgraduate education. These latter already have experience of this and I feel that by co-operation with approved hospitals they could create and organize a postgraduate teaching service second to none in the world. Teaching, both clinical and academic, would be fostered, and research encouraged—all in their rightful proportions.—I am, etc.,

London, W.1.

CHARLES D. READ.

Disseminated Sclerosis: Corrections

SIR,—I would be glad if you would correct the following errors in your report of my Presidential Address (Oct. 19, p. 587) on "The Problem of Disseminated Sclerosis," which are somewhat misleading.

(1) "Some recent work in Moscow" is contained in a paper by M. S. Margulis, V. D. Soloviev, and A. K. Shubladze, which is published in the current number of the *Journal of Neurology, Neurosurgery, and Psychiatry*. They claim isolation of a virus from two cases of acute disseminated encephalomyelitis, but no similar claim is made for disseminated sclerosis as implied in your report.

(2) In discussing the known pathways of infection in toxic-infective diseases of the nervous system, reference was made to the attention given, in the early part of this century, to the peripheral nervous system as the route of infection by the sequence of events in rabies, tetanus, and diphtheria, and not in disseminated sclerosis as suggested by your report.

(3) Reference was made to a survey of 142 cases of disseminated sclerosis; these cases were collected over a period of four years and not one year as stated.—I am, etc.,

Middlesex Hospital, W.1.

DOUGLAS MCALPINE.

BRITISH ORTHOPAEDIC ASSOCIATION

Orthopaedists assembled in London for a very full annual meeting on Oct. 18 and 19. Discussion, presidential address, papers, and films occupied the first day at the Royal Society of Medicine, dinner was at Grosvenor House, and business meeting and clinical demonstrations followed next morning at St. Thomas's Hospital.

Annual Dinner

The British Orthopaedic Association is a well-established authoritative body, and certainly added to its stature by the brilliance of its annual dinner of twenty-one tables, at which austerity fare, uniform, and lounge suits were all giving way to roast duckling and boiled shirts. The President, Mr. George Perkins, welcomed the return of the members' ladies, and toasted as official guests the Prime Minister, the Ministers of Health and of National Insurance, and a number of foreign orthopaedists. Sir Heneage Ogilvie (Vice-President, Royal College of Surgeons) proposed the health of the Association with wit and wisdom. Sir Reginald Watson-Jones (Orthopaedic Surgeon to the King) deplored the lack of spontaneous song and smiles in England to-day and laid some responsibility upon those who sought to regiment the flowers rather than place reliance upon "the unofficial English Rose." He said he did not want to be a Civil Servant and would not be a Civil Servant. Mr. Attlee pleaded for happiness derived from freedom on an ordered plan of co-operation" and instanced example of the equalitarian countries. Mr. Bevan, reminding his audience, with apt orthopaedic metaphor, of the many tied stems in "the unofficial English Rose," explained that he sought "to put the best kind of medical apparatus in the hands of the profession for them to use it freely and independently for the maximum benefit of the patients," and added: "My relations with the British Medical Association are growing more friendly week by week." (He had that day made an announcement about discussions on the capitation fee for insurance practitioners, which will be found in the *Supplement*.) The Minister of National Insurance spoke of his own debt to orthopaedists after a mining accident and declared that the best planned orthopaedic service was desirable to combat the high incidence of accidents in this vital industry.

The meeting showed that orthopaedists will carry to the post-war world a rationalized amplified service gained from their interchange of abundant wartime experiences.

The Central Council for Health Education has revised its committee structure, resulting in the constitution of two major committees dealing respectively with field work and with materials in Health Education. At the first meetings of these new committees Dr. A. B. Williamson, M.O.H. for Portsmouth, was appointed chairman of the field work committee, and Dr. H. Maurice Williams, M.O.H. for Southampton, was appointed chairman of the materials committee.

Obituary

C. S. MYERS, C.B.E., M.D., F.R.S.

We regret to announce that Dr. Charles S. Myers, the eminent psychologist and a pioneer in industrial psychology, died suddenly at his home, Winsford, near Minchhead, Somerset, on Oct. 12. His life work has had a profound influence on the selection of personnel for industry and for military service. He taught the significance of the human factor, trained a band of enthusiastic disciples in the techniques of investigation, and persuaded many large industrial firms to employ a psychological consultant.

Charles Samuel Myers was born in London on March 13, 1873, and from the City of London School entered Caius College, Cambridge, where he won first-class honours in Parts 1 and 2 of the Natural Sciences Tripos and was appointed Arnold Gerstenberg student by the University. He went on to St. Bartholomew's Hospital for his clinical course and graduated M.B., B.Ch. in 1898, in which year he travelled with the Cambridge Anthropological Expedition to Torres Straits and Sarawak. On his return he became house-physician at Bart's and proceeded M.D. in 1901 and was elected a Fellow of his College. While living at Cambridge he became Reader in Experimental Psychology and Director of the Psychological Laboratory; he also held for three years the chair of psychology at King's College, London. Myers was the first president of the British Psychological Society and edited the *British Journal of Psychology* from 1911 to 1924. Meanwhile he had taken the Cambridge degree of Sc.D. and was elected F.R.S. in 1915. He did outstanding work for a long time as Principal of the National Institute of Industrial Psychology and later became its honorary scientific adviser. He presided over the International Congress of Psychology in 1923, gave the Herbert Spencer Lecture at Oxford in 1929, the Hobhouse Memorial Lecture in London in 1932, the Joule Memorial Lecture at Manchester in 1933, and in the same year the Bradshaw Lecture before the Royal College of Physicians of London on "A Psychological Regard for Medical Education."

Myers did valuable work as consulting psychologist to the British Armies in France in the war of 1914-18 with the rank of lieutenant-col., R.A.M.C.; making a particular study of what was then termed "shell shock," and he was one of the first to join the Advisory Committee on Personnel Selection set up later by the War Office. He had also been a member of the Home Office Factory Lighting Committee and of the Industrial Health Research Board. The University of Manchester conferred on him the honorary degree of D.Sc., and the University of Calcutta its honorary LL.D. He wrote on the theoretical as well as the practical sides of his subject. Besides contributions to journals devoted to psychology, anthropology, medicine, and physiology, he published *Mind and Work* in 1920, *A Textbook of Experimental Psychology* (third edition, 1925), *Industrial Psychology in Great Britain* (second edition, 1933), and other books entitled *Business Rationalization* (1932), *A Psychologist's Point of View* (1933), *In the Realm of Mind* (1937), and with Henry J. Welch *Ten Years of Industrial Psychology*. A gifted scientist, he had remarkable prevision of the service that his branch of science could give in choosing people for the right job. The following reference to Myers's pioneer work as director of the National Institute for Industrial Psychology is quoted from a tribute in the *Manchester Guardian*: The institute grew, in fact, from his statement, while lecturing in 1919, that his Army experience had convinced him that psychology must be taken out of the laboratory and applied to the practical problems of life and work. One of his hearers, Mr. Henry Welch, a tea and rubber merchant, had himself thought of applying psychological methods to business appointments. They joined hands and started the institute.

HENRY HANNA, M.B., B.Sc.

Mr. Henry Hanna died suddenly at his residence in University Square, Belfast, on Sept. 28. A well-known figure to successive generations of medical students, he had many friends and

enjoyed a high reputation in the practice of otorhinolaryngology and ophthalmology.

Born in 1874 he was educated at the Belfast Royal Academy, Queen's College, Belfast, and St. John's College, Cambridge. He held Royal University of Ireland conferred on him the degree of B.A. in 1894 and the M.A. and B.Sc. in 1896. After, he took up the study of medicine and graduated M.B. in 1903. Then followed a time as resident medical officer at the Royal Victoria Hospital, Belfast, a period as demonstrator of anatomy in the University, and finally a course of post-graduate study in his chosen subjects at Vienna. After this he set up in specialist practice in Belfast and was appointed to the visiting staffs of the Royal Victoria Hospital and of the Belfast Infirmary, now the City Hospital. He retired from the "Royal" in 1939, in his last year holding office as chairman of staff, but throughout the war, like other consultant members of the staff, he came to the aid of the hospital to make up for loss of the services of those who had joined the Armed Forces. Some measure of his vitality and continued interest in his work is shown by the fact that he retained his active position on the staff of the City Hospital (a connexion going back for well over 15 years) until the time of his death.

In his early days he was trained as a biologist and for a time he taught botany and geology at the Royal College of Science in Dublin. These experiences, his friends recognized, did much to influence his life and to determine the nature of his subsequent interests and pursuits. He was an enthusiastic collector and in his house had many valuable pictures, pieces of porcelain, and exquisite examples of old Irish glass. Outdoors, his hobbies took him in a variety of directions, but he was perhaps most happy with the rod, and each year he spent many evenings, regularly during the summer months, by the water fishing.

Mr. Hanna took his part in public life, being a past president of the Ulster Medical Society, the Irish Ophthalmological Society, and of his own special section at the British Medical Association's meeting in Belfast in 1937. But he was reserved as a rule in large gatherings unless some matter urged on him the necessity for speaking (which he then did most effectively). Unquestionably he enjoyed more the happiness of his own fireside with his wife and children and their friends or the chance encounter with his colleagues, when they would be sure to glean some appreciation of his dry wit and shrewd ability to assess both situations and persons. At times irascible, he had a strong sense of justice, but his nature was warm at heart and deeply appreciative of the trials and sufferings of others.

News has been received from Auckland of the death on Oct. 3 after a long illness of Dr. ROBERT HALDANE MACKILL, C.B.E., who before his retirement in 1932 had been medical officer in the Government Health Department of New Zealand for 31 years. A native of Scotland, he was born in 1870, second son of Sir John Mackill, of Kemback, Fife, 10th baronet. He graduated M.B., C.M. at Edinburgh University in 1893, proceeded M.D. in 1899, and took the Cambridge D.P.H. in 1901 after service in the South African war as civil surgeon with the Natal Field Force. During the war of 1914-18 he held a commission in the R.A.M.C. and served at Alexandria with the Sanitary Branch of the Egyptian Expeditionary Force for a year, and then was appointed A.D.M.S. (San.) with the N.Z. Expeditionary Force. Dr. Mackill was created C.B.E. in 1919 for his work in the war, and had been honorary pathologist to the Auckland Hospital and M.O.H. for Auckland.

Dr. NORMAN F. ELLIOTT BURROWS, late Surg. Lieut.-Cmdr., R.N.V.R., sends the following tribute to Dr. T. WATTS EDEN: "Although many of his contemporaries and colleagues will pay their tributes to Dr. Eden, may I, as representing a very much younger vintage, say how much I deplore his death, and what a loss the medical world has sustained by his passing. I first met him at the end of 1944 when I was stationed in Devon with the Marines. He paid a courtesy call to my sick bay, and having introduced himself as Dr. Eden, I immediately asked him if he was any relation to the Eden of Eden and Holland. I shall always remember the look of pardonable pride on his face as he replied simply, 'I am Eden.' He was one of the most gentlemanly, unselfish, and mentally alert people it has been my pleasure to meet, and in these days of hurry, lack of courtesy, and materialism it is refreshing to have met and enjoyed the company of a man of his calibre.

The Services

A PRESENTATION BY ARMY CONSULTANTS

On Oct. 14 at the Royal Society of Medicine the Army medical consultants, now demobilized, presented to the Director-General A.M.S., Lieut.-Gen. Sir Alexander Hood, for the headquarters mess of the R.A.M.C. at Millbank, an album containing the portraits and records of service of members of the medical and dental professions who served as consultants and advisers with the land forces of the British Empire at home and overseas during the second world war. A sum of money was also presented to the Royal Army Medical College for the endowment of a prize.

Sir Heneage Ogilvie, who made the presentations, said that he thought it could be claimed, without undue boasting, that the British soldier in the recent war had had better medical attention than any soldier of any army had ever received before in military history, and this was largely due to the happy association and loyal co-operation which prevailed during the momentous years of war between the regular officers of the Army Medical Service and those who, from all branches of medicine, were only too eager to join for the period of the war a service of such high traditions.

Sir Alexander Hood, in accepting the gifts on behalf of the Service, said that his first acquaintance with the consultants was in 1930 in France when a very happy band were gathered together in Dieppe, and used to come up to the fastness where he and his brother officers were lodged in Arras, bringing with them not only great stores of knowledge and wisdom, but also certain provender which was extremely acceptable. His next experience of them was when he came to the War Office and got into touch with a large number of most co-operative and busy people whose services the Army was very fortunate to command. He referred to some distinctive achievements, one of them the production of the *Army Medical Bulletin* the first number of which was published early in 1941, and the last—the 51st—in June, 1945. The *Bulletin* was looked forward to by medical officers all over the world. Then there were the consultants' meetings, when sometimes as many as forty would sit round the table, the number including some from the American and Dominion Armies, and also French and Belgians and people from the E.M.S. and the Medical Research Council. Many consultants were fortunate enough to go far overseas. He thought there was not the slightest doubt that the standard of medicine and surgery in India, West Africa, and elsewhere owed a tremendous amount to the work of the consultants who were serving there with the Army. "You can look back on your achievements with great satisfaction. If sometimes the administrative machine seemed to you to suffer from considerable inertia, please remember that we did our best. We were a happy party, and it is by having happy people work with one that the best work is done. I look back on this association as covering some of my happiest days in the Army. I agree that the British soldier was better looked after in this war than any soldier has ever been, and that was due very largely to the consultants who served with us."

FL-Lieut. C. B. I. Willey, M.C., R.A.F.V.R., has been appointed M.B.E. (Military Division) in recognition of gallant and distinguished services rendered during the period of operations against the Japanese in Malaya and the Netherlands East Indies terminating in March, 1942. He has also been mentioned in dispatches in recognition of gallant and distinguished services while a prisoner of war in Japanese hands.

Acting Squad.-Ldr. R. A. Cumming, R.A.F., has been appointed O.B.E. (Military Division) in recognition of gallant and distinguished services while a prisoner of war in Japanese hands. His name also appears in a list of people mentioned in dispatches in recognition of gallant and distinguished services in Malaya, Hong Kong, and the Netherlands East Indies during the operations against the Japanese terminating in March, 1942.

The Queen of the Netherlands has conferred the decoration of Knight Officer of the Order of Orange Nassau with Swords upon Major G. F. Bramley, and Major (Temp.) H. Kennedy, M.B.E., R.A.M.C., in recognition of distinguished services in the cause of the Allies.

The following decorations have been conferred by the President of the U.S.A. in recognition of distinguished services in the cause of the Allies. *Legion of Merit, Degree of Commander*: Brig. (Temp.) H. L. G. Hughes, C.B.E., D.S.O., M.C., R.A.M.C. *Legion of Merit, Degree of Officer*: Lieut.-Col. A. N. B. Odbert, O.B.E., R.A.M.C. *Legion of Merit, Degree of Legionnaire*: Col. T. Young, O.B.E., R.A.M.C. *Silver Star Medal*: Lieut. J. D. Devitt, R.A.M.C.

surgical research, a moving spirit in surgical education, an operator, an inspiring writer, and a well-loved teacher. Sir Henry

said that Dr. Whipple had so often directed and helped him in the past that he felt particular pleasure in having him for a brief period in his charge. "We honour him, not for his many distinctions, but for the ability that earned those distinctions, not for the many important offices he holds or has held, but for the outstanding qualities of mind and character that have earned him those appointments. Dr. Whipple's name is printed large on every page of surgical advance, and where other surgeons are breaking new ground and treading fearfully, as they are to-day in the surgery of malignant diseases of the pancreas, there they see Allen Whipple before them saying: 'Here I am. This is the way I have gone, and where I have trodden you may follow safely.'"

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At the annual meeting of the College, held on Oct. 16, the following officers were elected for the ensuing year:

President, Mr. James M. Graham. *Vice-President*, Prof. R. W. Johnstone. *Secretary and Treasurer*, Mr. K. Paterson Brown. *Representative on General Medical Council*, Sir Henry Wade. *Convener of Museum Committee*, Mr. W. Quarry Wood. *Librarian*, Dr. Douglas Guthrie.

The following, having passed the requisite examinations, were admitted Fellows:

N. Alders, C. J. B. Anderson, W. G. Birks, S. K. Burcher, A. G. S. Calder, E. A. Chisholm, L. M. David, F. W. T. Davies, A. J. Freese, G. L. Gale, M. P. Goradia, J. B. M. Green, F. M. Hanna, E. L. John, W. G. Kerr, J. E. Laing, W. H. S. Liebenberg, T. Levitt, A. A. MacGibbon, J. M. McInroy, T. B. McMurray, J. M. Matheson, K. N. Mitra, R. F. O'Driscoll, G. V. Osborne, A. P. R. Pinlo, E. C. Richardson, G. K. Riddoch, L. J. Roy, A. R. Taylor, D. J. Waterson, A. Young.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

A course of lectures on "Recent Advances affecting Obstetrical and Gynaecological Practice" will be given in the College House (58, Queen Anne Street, W.) on Fridays, Nov. 1, 15, and 29, Dec. 13, and Jan. 10, at 5 p.m. Admission is free, by ticket obtainable from the secretary of the College. Applicants should state for which lectures tickets are required. Details will be published in the diary column of the *Supplement* for the appropriate weeks.

Medical Notes in Parliament

HEALTH SERVICE BILL

Committee Stage in the House of Lords

The Committee Stage of the National Health Service Bill was begun in the House of Lords on Oct. 17.

The House agreed to Clause 1 of the Bill without discussion. On Clause 2 Lord MORAN moved to leave out subsections 3 and 4 dealing with the constitution and duties of Standing Advisory Committees and to substitute the following:

(3) The Central Council may, if the Minister so approves, appoint standing advisory committees for the purpose of assisting them in such manner and subject to such conditions, if any, as they may direct, in the exercise of their functions under subsection (1) of this section in regard to all or any matters relating to particular services provided under this Act. Any such standing advisory committee may consist either wholly of members of the Central Council or partly of members of the Central Council and partly of other persons being persons of experience in the particular service or services with which the committee is concerned.

Lord MORAN said he was anxious to make the Bill of value and did not wish to be associated with wrecking amendments. He moved this amendment to strengthen the Central Health Services Council. The difference between the Bill as it stood and his amendment was that in the Bill the Minister appointed Standing Committees and they reported directly to him. In his amendment the Council appointed these Standing Committees and they reported through the Council to the Minister. There was a general feeling throughout the profession, and the Negotiating Committee was unanimous, that if the Bill passed as it stood the Standing Committees would do the work and the Central Health Services Council would be robbed of its chief function. At the present time those actively engaged in the practice of their profession played little part in administering the health services and it was hoped that this Central Council would be a means by which those engaged in active practice could take an active part not merely once or twice a year but in everything important concerning health which came before the Minister.

In the House of Commons Mr. Bevan, in trying to define what the Central Health Services Council could do, gave as an example that the Central Council could not advise the Minister on putting up a gynaecological service. Lord MORAN took that example and explained that at present there was a dispute in the profession. The British Medical Association felt that every practitioner on the *Register* should have the right to attend midwifery cases. The Royal College of Obstetricians and Gynaecologists felt that only a practitioner who had special training should be allowed to attend confinements. Both felt strongly on this point. Supposing that the dispute had to be referred to the Committee of Gynaecologists the answer would not be in doubt but would not bring conviction to the profession generally. The Central Council should adjudicate between these two sections of the profession. The Minister, when he dealt with matters concerning general practitioners, had got into the habit—the right habit—of consulting the British Medical Association. He had not yet established the equally healthy habit of consulting the bodies which represented consultants and specialists. If the Bill was to be a success Parliament must make the profession feel it was responsible for that success. With the profession behind it there was some chance that the whole scheme would work really well.

The LORD CHANCELLOR (Lord JOWITT) said the Government could not accept the amendment. He himself had to sit on a body which consisted of less than twenty members but which found that the only way to get through its business was to refer a large number of specialist questions to subcommittees with power to act. Before the Minister appointed Standing Committees he had to consult with the Central Health Services Council. The Bill provided that the Standing Committees could report direct to the Minister but should also send a copy of their report to the Central Council so that the Council could make observations on it. That was a better plan than the Council of forty-one, which was bound to be unwieldy. Suppose there was a question relating to dentistry, was it necessary that the Government should wait for the report of the forty-one members, of whom two were registered pharmacists, one a midwife, and two registered nurses?

Lord MORAN said that the amendment only asked that the Central Council should appoint its own subcommittees rather than that committees which were not really subcommittees should be appointed by someone else. In view of what the Lord Chancellor had said he withdrew the amendment.

Lord MUNSTER asked Lord Jowitt to explain the provision in Clause 2 which said that the Minister, after consultation with the Central Council, could refrain from laying the annual report of that Council before Parliament if he was satisfied that it would be contrary to the public interest.

The LORD CHANCELLOR said the report might include matters connected with war or about a promising discovery made with regard to cancer which it would be undesirable in the public interest to release too soon. Apart from rare cases of that sort he did not think that the proviso would have to operate so long as peace remained.

The House then agreed to Clause 2 and Clause 3. On the motion of the LORD CHANCELLOR a drafting amendment was made in Clause 4 (Accommodation Available on Part Payment). In the same Clause the EARL OF MUNSTER moved to insert a proviso that where there was provided in any hospital accommodation in single rooms or small wards such accommodation should not be converted into larger rooms or wards. Lord Jowitt gave an assurance that such rooms would not be converted unless this was found necessary in the interests of the services provided by the hospital as a whole or in the wider interests of the co-ordinated hospital service. Lord MUNSTER withdrew his amendment but said he still feared that on account of the shortage of hospital accommodation Mr. Bevan would be forced to remove the whole of the private accommodation in many hospitals. Clause 4 was agreed to.

Accommodation for Private Patients

On Clause 5, subsection (2) begins: "The Minister may allow any medical practitioner serving on the staff of a hospital providing hospital and specialist services to make arrangements for the treatment of his private patients either at that hospital or at any other hospital."

Lord LEWELLIN moved to omit from this passage the words "serving on the staff of a hospital providing hospital and specialist services." He said the amendment would allow a doctor to follow his patient into a hospital even though that doctor was not a specialist on the staff of that hospital and would allow a patient to continue under the same doctor. The doctor who suited a patient best was the one who knew that patient's past history and had his confidence.

Lord SALTOUS said this difficulty was found in many hospitals to-day and was often covered by the hospitals making all

medical practitioners within a certain range honorary members of their staff.

Lord HORDER said that from the medical angle he gave emphatic support to the amendment. It was greatly in the interest of the patient on personal and on medical grounds that continuity should be preserved.

Lord LISTOWEL said that, under the Bill a doctor who remained outside the public service could give institutional as well as domiciliary treatment to his patients. The patient could have an operation in a nursing home from a doctor who remained outside the service. The amendment would allow a specialist or general practitioner who chose to stay outside the public service to use for his private work hospitals provided at the public expense.

Lord CRANBORNE said the patient had made his contribution to the State scheme and the Opposition felt that when he entered the State hospital he should be limited only to the State treatment. The medical practitioner who was not a member of the State service could not under the Clause as it stood even arrange for his patient to be treated by somebody else at a State hospital. That practitioner was completely outlawed. The position was utterly unjustifiable. He could not believe that the people intended in setting up a State service that there should be this divorce between a physician and his patient. The Opposition favoured a State service but did not believe that there should be a continual whittling down of private practice so that in effect it was really useless.

Lord ADDISON said the practice of attaching medical practitioners in a district to a hospital was quite common. These men could take their patients in and no question would arise. But a hospital was an organization run by the staff and when medical practitioners outside sent their patients into the hospital they did not follow them themselves. The patients were treated by a member of the staff of the hospital and that was what the Bill proposed. The amendment proposed that for the purpose of private nursing a medical man would send his patient in, follow the patient in and thereby become a member of the staff. Hospitals could not be run on that indiscriminate basis. The practice now in existence was satisfactory.

Lord SWINTON said that if, as Lord Addison had argued, there was to be no alteration in the existing position there need be no Clause. The effect of the Clause was to give a special privilege to a particular class of doctor. Lord LLEWELLIN asked whether the words "serving on the staff" which were used in the subsection meant a full-time doctor on the staff. Lord ADDISON said they did not. Lord LLEWELLIN said he felt there might be some misunderstanding and his friends would like to reconsider the matter. He withdrew his amendment and Clause 5 as previously amended was agreed to.

Transfer of Hospitals to the Minister

Lord LISTOWEL said Clause 6 as drafted was too wide. It would transfer to the Minister property belonging to local authorities which was not part of a hospital. It would, for instance, transfer to him a site which had been bought for the purpose of building a hospital but had not been so used. He proposed an amendment to alter the wording of subsection (2) in order to afford protection to the local authorities. The House accepted the amendment.

Lord IDDESLEIGH moved to provide that on the transfer to the Minister of a voluntary hospital having associations which had it with a particular religious organization regard should be had in the general administration and in making appointments on the management committee and the staff to the preservation of that hospital's character and associations. He instanced The Retreat (the mental home provided by the Society of Friends), the Jewish Hospitals, and the numerous Roman Catholic hospitals.

The LORD CHANCELLOR said Mr. Bevan had already given an undertaking broadly on those lines. The Minister could not sacrifice medical considerations, but so far as practicable it was right that the Ministry should maintain and uphold the denominational character of these hospitals. He would look into the matter before the Report Stage and see how far he could go to meet Lord Iddesleigh.

The amendment was withdrawn and the House agreed to Clause 6.

On Clause 7 Lord MAUGHAM moved to insert at the end of subsection (4) a proviso that in the case of any endowments for which a special application or appropriation had been directed or declared by the donor, the Minister should, so far as practicable, secure that the directions of the donor should not be prejudiced.

Lord READING, Lord LLEWELLIN, Lord SALTOUN, and the DUKE OF MONTROSE supported the amendment.

The LORD CHANCELLOR said that whereas with regard to the teaching hospitals no redistribution of funds was contemplated

it was of the essence of the National Health Service Scheme that there should be a redistribution of the funds of the voluntary hospitals. The Chancellor of the Exchequer had been persuaded to agree that the endowments of voluntary hospitals should remain for teaching purposes so that the hospitals would have a cushion between themselves and the rigour of Treasury control, but there were also the municipal hospitals which had no endowments and some voluntary hospitals which were inadequately endowed. It therefore seemed right to the Government that there should be a redistribution of endowments of voluntary hospitals so that all the hospitals which were going to form part of a common service should be able to share in the proceeds. It was probable that the capital value of the endowments was about £50,000,000, but that contained part of the endowments of the teaching hospitals.

Lord LLEWELLIN said the object of the amendment was to ensure that hospitals, or parts of hospitals, given as voluntary hospitals, were continued. Lord MAUGHAM thought that the action contemplated by the Government was a breach of trust. Lord SAMUEL did not think that the purposes of ancient endowments would be satisfied if the old voluntary hospitals were continued with comforts and amenities while the municipal hospitals were bare and barren of additional comforts. What the donors desired was that the sick should be well cared for and happy.

Lord LONDONDERRY said he understood that if a hospital was well endowed and could produce an income every year the Exchequer would provide a lesser sum for the benefit of the hospital than if the circumstances were otherwise.

The LORD CHANCELLOR replied that that was not so. He said he could not weaken on this question. If money was left for the Reigate Hospital the intention of the Government was that this money should be taken, put into the pool, and distributed among other hospitals. If there were some special case such as that of a gift which involved the maintenance of a garden he would consider whether he could devise some way to meet it provided these words were confined to special cases.

The amendment was withdrawn and Lord LLEWELLIN moved to add after subsection (4) a proviso dealing with the interim period before the appointed day. Those who in the past had done good work collecting money for hospitals still wished to collect sums for such things as additional comforts but feared that if they did so the money would go into the Endowment Fund. His amendment was that in the interim period a little fund could be built up.

The LORD CHANCELLOR said he felt sympathy about the matter. It was unlikely that between the passing of the Bill and the appointed day charitably minded people would lend money to the hospitals if they knew that on the appointed day it would be taken into a fund and pooled. He would consider whether before the Report Stage he could devise some appropriate form of words to meet this important point.

The amendment was withdrawn and the Committee agreed to drafting amendments proposed by Lord LISTOWEL. Clause 6 as amended was then agreed to and Clause 8 was adopted without amendment.

The House then adjourned.

Functions of Management Committees

The Committee stage of the Bill was resumed on Oct. 21. On Clause 12 Lord LUKE moved an amendment to readjust the functions as between the regional boards and the hospital management committees. He said that the management committees or groups of hospitals should have powers from the regional boards similar to those enjoyed from the Minister by the teaching hospitals. To take the appointment of hospital staff away from the management committees would bring about a divided loyalty and would introduce the factor of removal of control. If the Minister wanted responsible people to be members of management committees he should give them suitable responsibilities.

The LORD CHANCELLOR agreed that the success of the scheme would depend almost entirely upon a very wide measure of delegation. The real issue was on the question of machinery. It would be prescribed by regulation that the management committees should do all things in regard to the day-to-day running of hospitals and incurring expense on behalf of the regional boards, but questions of major policy would be for the boards.

Lord LLEWELLIN said that this was doing it the wrong way. In the Bill as drafted the hospital management committees were left with no powers, and he wanted it to be seen in the Bill that there was a real job of work to be done by these committees. Otherwise people would not be prepared to serve on them. Viscount SIMON said it should be possible to make it plain in the actual language of the Bill—and not leave it to regulation after the Bill had been passed—that the committees were going to have a job left to them.

Vitamins in disorders of the circulation

The following are suggestions for the application of vitamin therapy in certain disorders of the circulation. Other conditions of the circulatory system were dealt with in a similar form in the last issue of this Journal.

Condition	Indications	Therapeutic Agents																		
BLOOD DISEASES. Anemias.	Iron deficiency anaemias are frequently complicated by vitamin deficiencies. The macrocytic anaemias such as Addisonian pernicious anaemia and sprue have been found in preliminary trials to respond to folic acid.	COMPLEVITE. Tablets of 2 colours to be taken in equal numbers. One of each colour thrice daily provides: <table> <tr> <td>Vitamins</td><td>Minerals</td><td></td></tr> <tr> <td>A 4,000 i.u.</td><td>Ca -</td><td>160 mg.</td></tr> <tr> <td>B₁ 0.60mg</td><td>Fe -</td><td>68 mg.</td></tr> <tr> <td>C 20.0mg</td><td>Iodine</td><td>not less than 10</td></tr> <tr> <td>D 300 i.u.</td><td>Mn.</td><td>p.p.m.</td></tr> <tr> <td></td><td>Cu</td><td></td></tr> </table> <p>It is hoped that folic acid will soon be available in this country for therapeutic trial.</p>	Vitamins	Minerals		A 4,000 i.u. THE CHOICE OF A SULPHONAMIDE

For the treatment of bacterial infections the sulphonamide preferred is one of high antibacterial activity, by means of which therapeutic blood levels can be rapidly achieved and easily maintained, with minimal toxic manifestations.

These desiderata are to be found in 'Sulphamezathine', a new sulphonamide which many authorities consider to be the drug of choice for use in pneumonia, meningitis, haemolytic streptococcal infections and *Bact. coli* infections of the urinary tract.

Highly efficient therapeutically, 'Sulphamezathine' is well tolerated and has little tendency to produce unpleasant effects such as nausea, vomiting or cyanosis. By reason of its ready solubility, renal complications are rarely encountered—a decided advantage over many sulphonamides.

Powder: Containers of 25 grammes, 100 grammes and 500 grammes.

Tablets: 0.5 gramme: Containers of 25, 100 and 500.

Ampoules: 1 gramme (in 3 c.c.): boxes of 6 and 25.
3 grammes (in 9 c.c.): boxes of 5 and 25.

Obtainable through your usual suppliers.

It is hoped
that Doctors will accept
this invitation to inspect
this *new* sanitary tampon.

Every carton of Lil-lets Sanitary Tampons states that the
unmarried woman and young girl should only use tampons
recommended to do so by her doctor. . . . You will
to examine that upon which you may be asked for
vice.

An uncompressed specimen, together with the carton of
one dozen as sold commercially will be sent on receipt of
professional card, and this will enable doctors to examine
the construction, size, finish and packing of Lil-lets.

Lil-lets are sanitary towels compressed to small tampon
shape. They are made of highly absorbent cotton, wholly
contained in fine absorbent gauze to eliminate risk of
particles becoming detached. Each is coated with a thin,
instantly soluble and innocuous film which assists easy
insertion without requiring an applicator. Receipt of your
professional card without other enclosure will be taken as
permission to send the specimens.

THE OLD MEDICAL SCHOOL, PARK ST.,
LEEDS 1. Telephone 20085

The LORD CHANCELLOR said that it would be possible to do what the amendment suggested, but quite deliberately it was not being done. It was provided that the hospital management committees might exercise on behalf of the regional hospital boards certain functions which were to be prescribed. He wanted the boards to leave a very wide discretion to the hospital management committees, and he believed that that was the best way of securing a co-ordinated system.

Viscount CRANBORNE asked that the Government should give the matter a little more thought. The LORD CHANCELLOR undertook to consider the matter further and the amendment was withdrawn.

Teaching and Research Facilities

LORD MORAN moved an amendment the main purpose of which was to ensure the setting up of medical staff committees in the hospitals. He said that in the voluntary hospitals there were such committees who kept the hospitals up to date. The matter was important because it was the very root of the efficiency of the administration of the voluntary hospitals.

LORD HORDER said he would be satisfied with an assurance that it would be within the power of the hospital management committees to encourage the setting up of medical staff committees.

The LORD CHANCELLOR said that he would desire to encourage the setting up of medical staff committees rather than providing that the hospital management committees should arrange for them to be set up. The initiative of the medical staffs on this matter would not only be welcomed but it would be regarded as lamentable if they did not take the initiative. He was reluctant, however, to put a provision in the Bill, and preferred to leave it to regulations. The amendment was, by leave, withdrawn.

LORD MORAN moved a further amendment to secure that the board of governors of every teaching hospital should provide those facilities for medical teaching and research required by the university or medical school with whom the teaching hospital was associated. He feared that in time the board of management might feel that there was extravagance and that more was being done than the comfort of the patient warranted, with a consequent weakening of teaching and research in the hospital. LORD HORDER and LORD CHERWELL supported the amendment.

The LORD CHANCELLOR said that it was fundamental that there should be facilities for teaching and research, but he thought it was going a little too far to provide whatever facilities the universities might require. He undertook to see if some suitable words could be drafted to meet the point. The amendment was withdrawn.

Legal Status of Management Committees

On Clause 13 LORD LLEWELLIN moved an amendment to provide that hospital management committees might sue or be sued, and have their own right to make contracts for the daily services of the hospital. He said that if they had to refer back to the regional boards they would become mere ciphers and there would be a complete lack of decentralization.

The LORD CHANCELLOR said that in certain of their actions the management committees could sue or be sued in the ordinary way. It was only when they were acting on behalf of the regional boards that they could not. In a co-ordinated scheme there must be a chain of authority involving the Minister at the top, the regional board, and the management committee acting on behalf of the board. It did not mean that the management committees were mere ciphers any more than estate agents were.

Viscount CRANBORNE said that the logical conclusion to draw from the Lord Chancellor's argument was that the only really responsible person was the Minister, and yet certain responsibilities were conferred on the regional boards. In that case, why not confer responsibilities on the management committees?

LORD INMAN said that he had received numerous letters from people who were leaving voluntary hospital work because they were losing their responsibilities, and he hoped that a compromise might be reached.

The amendment was carried against the Government by 59 votes to 17—Opposition majority, 42.

Appointment of Officers

On Clause 14 LORD LUKE moved an amendment which would have the effect of enabling appointments of staff to be in the hands of hospital management committees instead of in those of the regional hospital boards, as the Bill proposed.

The EARL OF LISTOWEL said that in fact the whole of the medical, nursing, and domestic staffs, except for a few specialists at the top, would be chosen, appointed, and if need be dismissed by the hospital management committees. LORD

LLEWELLIN said that it did not appear from the terms of the Bill that the Minister would be able to make regulations to that effect, since the staffs who looked after the hospitals would be officers of the regional boards.

The LORD CHANCELLOR said he could not state what the regulation would be, but the broad line was that certain matters would be within the province of the committees, including the appointment and dismissal of staff—with the exception of the senior staffs. He did not think there would be anything in the nature of an appeal to the regional hospital board in the case of a member of the staff being dismissed. Viscount CRANBORNE said that the Opposition wanted the hospital management committees to be able to appoint and dismiss staffs, and they insisted that that should be put in the Bill.

Viscount ADDISON said that amendments such as this would torpedo the possibility of a regional scheme. LORD LLEWELLIN said that they had been assured that these officers would, when the regulations came out, be officers of the regional board, but in fact they would be subject to dismissal by the management committee. It should be shown in the Bill to whom these officers really belonged. LORD INMAN said there were advantages in the Government's scheme. It would be convenient, for instance, to have accountants spread throughout a region and not attached to one hospital. Nurses, too, liked to move from one hospital to another, and did not want to be tied to one particular hospital. Viscount CRANBORNE suggested that there might be some differentiation between types of officers. As the word was used it covered both a hall-porter and a lung specialist, and whereas there would be advantages in a specialist ranging throughout an area that advantage would not apply to a porter. The amendment was negatived.

Maternity and Child Welfare

On Clause 19 LORD BALFOUR OF BURLEIGH moved an amendment to give power to the L.C.C. to delegate maternity and child welfare and ancillary services to the City and the metropolitan boroughs. He said that in the autumn of 1945 this arrangement was unanimously recommended at a meeting of the L.C.C. and no one had yet explained why they had changed their minds. Rumour had it that Lord Latham had said it should be so and it was so. In that case Lord Latham was a dictator, and this mixture of Hitlerism and bumbledom should be swept from the Bill. The MARQUESS OF ABERDEEN and LORD JESSEL supported the amendment.

The LORD CHANCELLOR said that at the time the L.C.C. passed the resolution they were going to keep their hospitals, and since they did not want too much on their plate they were prepared to delegate these services. But now that they were losing their hospitals they had the time and the ability to conduct these other services. The functions that remained with the L.C.C. were the provision of health centres, at which most of the functions of maternity and child welfare would be carried out, domiciliary midwifery, the ambulance service, and the care and after-care of the sick. The Government thought it desirable to concentrate responsibility for the health services on the local authorities in any given area in one authority. Would it be wise to place responsibility for maternity and child welfare in the hands of the metropolitan boroughs while keeping responsibility for domiciliary midwifery in the county council? Was it wise to leave provision for health centres for general medical and dental services with the L.C.C. while leaving maternity clinics and infant welfare centres with the borough councils? The amendment would increase administrative friction and difficulty, and produce a loss of efficiency and co-ordination. The amendment would be a retrograde step. By all means let the county council develop on a regional basis and take in representatives of the borough councils, but it would not be wise or sensible administration to have one body dealing with the under-fives and another with the over-fives.

* The EARL OF MUNSTER, the MARQUESS OF READING, and LORD LLEWELLIN supported the amendment, which was carried—again against the Government—by 35 votes to 15—Opposition majority, 20.

Bread and Chalk

Answering Sir ERNEST GRAHAM-LITTLE on Oct. 8, Mr. STRACHEY said the amount of creta preparata which was added to flour had been decided after consultation with the scientific and medical advisers of the Ministry of Food and after recommendations had been made by the Medical Research Council and considered by the Standing Committee on Medical and Nutritional Problems. These bodies included leading physicians. It was not proposed to add to their numbers. Mr. Strachey thought it was preferable to continue to use the accurate term "creta preparata" for the substance, conforming to the specification of the *British Pharmacopoeia*, which was added to flour. Sir E. Graham-Little suggested the use,

in circulars and Parliamentary answers, of the word "chalk." Mr. Strachey replied that chalk, as popularly understood, was a substance of variable composition which might contain as little as 85% or as much as 99% of calcium carbonate.

On Oct. 9, in a further reply to Sir E. Graham-Little, Mr. Strachey said that although the extraction rate of flour was being lowered to 85% it was inadvisable to lower the rate of addition of creta preparata below the original recommendation. Alternative sources of calcium in the diet were short at present.

Answering Sir Wm. Darling on Oct. 8, Mr. Strachey said he was anxious to reduce the flour extraction rate to 80% as soon as practicable. In national bread, bakers were allowed to use, beside national flour, water, salt, and yeast, any of the following substances: white flour, oils and fats, improvers in the nature of yeast food, any acid or acidic substances for regulating the acidity of the dough, potato and potato flour, barm.

Long-term View on Loans

On Oct. 8 Sir E. GRAHAM-LITTLE asked what provision was made for the resettlement in practice of medical practitioners whose houses were mortgaged to insurance companies at the time of their call-up to the Forces and who were faced with foreclosure by the insurance companies and found themselves, on demobilization, homeless and without means to buy another practice.

Mr. BEVAN replied that the arrangements made to assist the resettlement of medical officers discharged from the Forces did not include the provision of money for the purchase of a practice which could normally be obtained from the financial agencies with whom the medical profession were accustomed to deal. In the particular case to which Sir Ernest had drawn attention there might be hardship due to special difficulty in obtaining a loan in this way, but if the Health Service Bill was approved by Parliament the purchase of a practice would, when the Service came into force, no longer be necessary.

Surgical Boots

On Oct. 10 Mr. PRESCOTT asked whether the Minister of Pensions was aware of the delay still experienced in the repair and provision of surgical boots for disabled ex-Service-men.

Mr. PALING said production was still somewhat below demand in this small specialized industry, but through the help of the Minister of Supply his Department's principal contractors would shortly move into a modern and larger factory. When the new factory was in full operation output would meet demand.

Inter-Departmental Committee on Dentistry

Mr. BAIRD asked on Oct. 11 what action was proposed to give effect to the final report of the Inter-Departmental Committee on Dentistry.

Mr. BEVAN said the recommendations of the committee concerned measures to secure an adequate number of dentists for the population, legislation dealing with the practice of dentistry and the government of the dental profession, and matters concerning dental research. Many of the proposals were in the first place subjects for educational authorities. The Government had invited universities, dental schools, and teaching hospitals to consider the Report, and would consider introducing as soon as practicable legislation relating to those recommendations which dealt with the practice of dentistry and the government of the dental profession. The Government appreciated the importance of dental care as part of a comprehensive health service, and had already decided to provide the University Grants Committee with an additional sum of £100,000 for distribution during 1946-7 to assist dental schools in meeting increased recurrent expenditure resulting from an increased intake of dental students. They agreed that grants towards capital expenditure by dental schools for the same purpose should be made through the Medical Grants Committee. The Medical Research Council had accepted a recommendation that to assist them in their work in this field they should reconstitute their Dental Research Committee. The Council would be able to finance this work from the general grant-in-aid which they received from the Exchequer.

Pasteurization

Mr. TOM WILLIAMS, replying to Lieut.-Col. SHARP on Oct. 14, stated that where tubercle bacilli are found in a bulk sample of milk taken in a consuming area, the offending cow, if still in the herd, is usually detected very quickly, but in a small minority of cases there may be some unavoidable delay, due to the need

for biological tests. The point raised in the latter part of the Question, whether he would exercise his powers under the Food and Drugs (Adulteration) Act, 1938, and order immediate pasteurization of the milk from a particular herd, was under consideration by the Departments concerned in connexion with the revision of the Milk and Dairies Regulations.

Medical Research Council

On Oct. 15 Major VERNON asked the numbers of staff employed by the Medical Research Council and the salaries paid in the categories. Mr. HERBERT MORRISON furnished this table:

Staff Employed by M.R.C.

	Numbers	Salaries
Administrative officers ..	10	590-£750
Scientific staff, including qualified assistants ..	204	300-2,500
Other staff paid monthly ..	171	250-750
Established staff paid weekly ..	63	Under 250
Temporary staff paid weekly (mainly under age 21) ..	96	Under 250

In addition, 15 scientific officers and 8 temporary staff paid weekly are employed on a part-time basis, with salaries *pro rata* within the ranges given above.

Sweets and Teeth

Mr. PETER FREEMAN on Oct. 15 drew attention to experiments on 45 children performed by Dr. J. D. King, of the Medical Research Council, over periods of six months and two years. He said such experiments were calculated, in the opinion of medical authorities at the time, to injure the teeth of the children. He asked why children from an orphanage were chosen.

Mr. HERBERT MORRISON answered that the experiment involved giving a small extra ration of sweets to a number of children whose dental condition was under observation. The children were kept under constant supervision throughout to ensure that they suffered no ill effects from the experiment, which would have been stopped at once if there seemed to be any danger of this. In fact, as had been expected, there were no ill-effects and the children thoroughly enjoyed the experiment. It was necessary to study children in institutions owing to the need for an adequate number of subjects living under identical conditions on a known diet.

Priority Milk

Answering Sir HENRY MORRIS-JONES on Oct. 16, Dr. SUMMERSKILL dealt with milk supplies. She said she had reviewed the allocation of milk between priority and non-priority consumers after consultation with the standing committee on medical and nutritional problems. She hoped it would not be necessary to reduce the supply to non-priority adults below two pints per week during the winter. She would increase it above that figure as soon as the output rose in the spring. She was not prepared to reduce the quantities supplied to mothers and children below the present amounts, which her medical advisers recommended as essential. She could not make special arrangements in the case of the elderly or people living alone.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* an increased incidence was recorded for measles 320, scarlet fever 78, and diphtheria 34; cases of whooping-cough declined by 140.

Changes in the local returns for scarlet fever were barely appreciable except for increases in London 26, Lancashire 26, and Middlesex 20. The largest increases in notification of diphtheria were Lancashire 12 and Glamorganshire 11. A further decline in whooping-cough was general throughout the country and no large variations in incidence were reported. In Devonshire the notifications of measles fell by 107, but in all the other areas a rise occurred, notably in Lancashire 121. The largest return for dysentery was Warwickshire, Birmingham C.B. 7.

In *Scotland* infectious diseases generally were more prevalent and rises included scarlet fever 50, acute primary pneumonia 47, measles 38, and diphtheria 26. The only exception to the general trend was a fall of 9 in the notifications of cerebro-spinal fever. The incidence of this disease was at the lowest level for over a year. The increase in diphtheria was mainly contributed by the Western Area, where the number of cases

se from 57 to 86. The rise in the incidence of scarlet fever as fairly general; the largest increase was 24 in Glasgow.

In *Eire* a general increase was recorded for diphtheria 18 and measles 23. Although the notifications of diarrhoea and enteritis increased by 1 for the whole country, a fall of 9 was recorded in Dublin C.B.

Typhoid and Paratyphoid Outbreaks

Up to Oct. 21 there were 47 cases of typhoid in Armagh ever Hospital and 12 cases in other fever hospitals. The diagnosis has yet to be confirmed bacteriologically in only two of the Armagh cases. The source of the infection—which is now under control—was a milk supplier.

At Sheffield there has been a mild outbreak of paratyphoid fever involving so far 24 cases.

Quarterly Returns for Northern Ireland

During the June quarter the births were equivalent to a rate of 23.8 per 1,000, which is 1.0 above the corresponding quarter of 1945 but 0.6 below the average for the second quarters of the five years 1941-5. The infant mortality was 55 per 1,000 registered births compared with an average rate of 69 for the second quarters of the five preceding years. The deaths of only 6 women were attributed to diseases and accidents of pregnancy and childbirth, representing a rate of 0.8 per 1,000 births, which is 2.7 below the average of the corresponding quarters of 1941-5. The general death-rate was 12.1 per 1,000 and was 1.6 below the five years' average. Diarrhoea and enteritis in children under 2 was responsible for 58 deaths. There were 117 deaths due to pulmonary tuberculosis and 79 due to other forms of tuberculosis. These were 22 and 6, respectively, below the averages of the June quarters for the five preceding years.

Week Ending October 12

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,106, whooping-cough 1,362, diphtheria 269, measles 2,005, acute pneumonia 351, cerebrospinal fever 37, dysentery 44, acute poliomyelitis 22, paratyphoid 6, typhoid 3.

Ten-year Summary

The Minister of Health furnished on Oct. 16 the following table setting out the incidence of certain infectious diseases:

England and Wales

	Diphtheria		Scarlet Fever	
	Cases Notified	Deaths	Cases Notified	Deaths
1936	57,795	3,003	104,862	440
1937	61,341	2,898	95,735	305
1938	65,008	2,861	99,278	311
1939	47,343	2,133	78,101	181
1940	46,280	2,480	65,302	154
1941	50,804	2,641	59,433	133
1942	41,404	1,827	85,084	104
1943	34,662	1,371	116,034	134
1944*	23,199	934	92,671	107
1945*	18,596	722	73,687	84

	Measles		Whooping-cough		Chickenpox†
	Cases Notified	Deaths	Cases Notified	Deaths	Deaths
1936	Not notifiable	2,593	Not notifiable	1,918	23
1937	"	980	"	1,600	19
1938	"	1,524	"	1,052	18
1939	"	303	"	1,229	18
1940	409,521	857	53,607	678	10
1941	409,715	1,145	173,330	2,383	28
1942	286,341	458	66,016	799	16
1943	376,104	773	96,136	1,114	19
1944*	158,479	243	94,044	1,054	24
1945*	446,796	729	62,691	689	9

* Notifications for years 1944 and 1945 include corrections of diagnoses made at infectious disease hospitals; material for an exact comparison with the years 1936-43 is not available.

† Chickenpox is not a notifiable disease.

Tuberculosis in Vienna

New cases of tuberculosis notified in Vienna during the last six months were: 491 new cases in April, 481 in May, 586 in June, 369 in July, 382 in August, and 335 in September. The number of beds at present available for cases of tuberculosis in Vienna is 2,500.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct. 5

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county) (c) Scotland, (d) *Eire*, (e) Northern Ireland

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county) (c) The 16 principal towns in Scotland, (d) The 13 principal towns in *Eire*, (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1946					1945 (Corresponding Week)

Medical News

The 20th annual Lloyd Roberts' Lecture will be delivered in the Physiology Theatre of Manchester University by Prof. Michael Polanyi, F.R.S., on Tuesday, Nov. 19, at 4.15 p.m. Subject: "The Foundations of Academic Freedom."

The following programme has been arranged for the tenth anniversary celebrations of the founding of the Empire Rheumatism Council. Friday, Oct. 25, 7.15 p.m., Heberden Society Dinner to welcome official Swedish delegates to the celebrations, at Euston Hotel, with Dr. C. W. Buckley in the chair. Saturday, Oct. 26, 11 a.m., Prof. J. A. Höjer will deliver an address on "The Organization of Treatment and Research into Rheumatism in Sweden," at the Medical Society of London, 11, Chandos Street, Cavendish Square, W., with Lord Horder in the chair, supported by His Excellency the Swedish Minister. Monday, Oct. 28, 4 p.m., Reception at the Hall of the Society of Apothecaries, Blackfriars Lane, E.C., guests will be received by Mr. Aneurin Bevan, Minister of Health, and Lord Horder, chairman of the Council. The guests of honour are the Swedish Minister, with Prof. J. A. Höjer and Dr. B. Strandell of the Royal Swedish Health Department, and Dr. Loring T. Swaim, of the American Rheumatism Association. There will be a message from H.R.H. the Duke of Gloucester. Tuesday, Oct. 29, 1.15 p.m., Lunch, to be given by H.M. Government, at Savoy Hotel, Strand, W.C., with Mr. Aneurin Bevan in the chair; 5.30 p.m., Reception by the British Council at 74, Brook Street, W.

A series of lectures will be given at the Royal Institute of Public Health and Hygiene, 28, Portland Place, W., on Wednesdays, Oct. 30 to Dec. 18, at 3.30 p.m. The lecturers and their subjects are: Dr. W. H. Bradley, "Methods adopted in the Detection of 'The Carrier'"; Dr. Brian Russell, "Some Possibilities in the Prevention of Disorders of the Skin"; Miss Barbara M. Duncum, D.Phil., "The Popular History of Anaesthesia"; Mr. C. W. A. Kimbell, F.R.C.S., "Medical Aspects of Life in the Prisoner of War Camp"; Miss Barbara Low, B.A., "Juvenile Delinquency"; Prof. Arnold Sorsby, F.R.C.S., "Blindness in Childhood—Past Achievements and Present Problems"; Sir Allen Daley, M.D., "The Public Health Services of London during the Past Hundred Years"; Dr. C. H. C. Toussaint, "Tuberculosis—The Objective and Its Approach." Seats are reserved for Fellows, Members, and Associates of the Institute, but accommodation is provided for others who are interested in health problems. The Museum of Hygiene may be viewed before or after the lectures.

At a meeting of the London Association of the Medical Women's Federation in the Hastings Hall of B.M.A. House on Tuesday, Nov. 5, at 8.30 p.m., Lady Florey will speak on "The Chemotherapy of Infected Wounds." Coffee at 8.15 p.m. in the Members' Common Room. The next meeting will be held on Friday, Dec. 6, when Dr. W. Ritchie Russell will speak on "Rehabilitation after Head Injuries."

The third Medical Research Society lecture will be given by W. J. Kolff on "The Artificial Kidney" at the University College Hospital Medical School, Gower Street, W.C., on Thursday, Nov. 7, at 5 p.m. Those professionally interested are invited to attend.

At a meeting of the Tuberculosis Association to be held at 26, Portland Place, W., on Friday, Nov. 15, at 3.15 p.m., Dr. J. F. Brailsford will read a paper on "The Technique and Standardization of Radiographs of the Chest," and after tea Dr. G. S. Todd and Dr. David Anderson will open a discussion on "Chest Diseases and Flying."

A meeting of those interested in a proposed Association of Plastic Surgeons will be held at the Royal College of Surgeons, Lincoln's Inn Fields, on Wednesday, Nov. 20, at 5 p.m. The President of the Royal College of Surgeons welcomes the formation of such an association and suggests that it should fall into line with other similar associations already affiliated to the Royal College of Surgeons.

Aberdeen University Court has appointed Dr. Alexander H. Macklin to the new post of medical officer with charge of the students' health services. He is at present physician in charge of the electrocardiographic department of Dundee Royal Infirmary.

The Home Office announces amending Orders made by the Secretary of State which came into operation on Oct. 15, bringing certain additional substances within the scope of the Poisons List and Rules. To Part I of the Poisons List there are added dihydrodesoxymorphine, and also pethidine and its salts. To Part II is added zinc phosphide. Dihydrodesoxymorphine, pethidine and its salts, and zinc phosphide are added to the First Schedule; but "articles containing zinc phosphide and prepared for the destruction of rats and mice" are exempted from First Schedule requirements by an amendment to Rule 10.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to the EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. House, Tavistock Square, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Western, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* and, unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publisher, B.M.A. House, Tavistock Square, LONDON, W.C.1, on receipt of proof. Authors over-seas should indicate on MSS. if reprints are required, as proof are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, LONDON, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Western, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Mediseca, Western, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Androgens, for Enlarged Prostate

Q.—*Since androgens are said to activate prostatic epithelium what is the rationale of treatment of senile enlargement of the prostate with androgens?*

A.—The theoretical basis for the use of androgens for enlarged prostate is the fact that sexual potency wanes in some men in the sixth and seventh decades, and sometimes earlier. There is also some evidence, based on biological assay of androgens in the urine, that there is decreased testicular secretion in these later phases of life when the prostate gland enlarges. However, it is equally true that androgens do activate prostatic epithelium. The committee set up by the Medical Research Council before the war came to the conclusion that no objective evidence was forthcoming in favour of the value of testosterone in senile enlargement of the prostate. On the other hand, most clinicians had the impression that the symptoms of the condition were subjectively improved.

There is no definite knowledge as to the endocrine aetiology of senile enlargement of the prostate, but the theory has been advanced that a relative preponderance of oestrogens in old age due to a deficiency of testosterone, is responsible. Experimentally, oestrogens will produce fibromuscular hypertrophy of the prostatic gland. Carcinoma of the prostate is treated by oestrogens on the theory that they produce a physiological castration, and possibly have a direct favourable action on the cancer. The subject as a whole, therefore, is seen to be quite involved.

Tender Granulation Tissue

Q.—*If the skin is removed from any part of the body the underlying tissue, except the actual nerves, is at first insensitive to pain. Later, when covered with granulation tissue, the exposed tissue becomes exquisitely tender. Why?*

A.—Sensitivity in granulation tissue is of two types. The first is generalized over the whole surface and is evoked by, say, the removal of a dressing. It is an indefinite pain, and is probably due to tension transmitted through the ingrowing vessels to their deeper sources. It may therefore be sympathetic in origin. The second type consists of acutely sensitive areas which are clearly defined and usually small. These are presumably sites of nerve-budding and are often found near the edge of the defect, where it is probable that a few exposed end organs persist.

Undescended Testicles

Q.—*What advice should be given to the parents of a boy, aged 10, healthy, and with no sign of endocrine defect, in whom the testicles are not in the scrotum and cannot be detected in the inguinal canal?*

A.—If the testicles are still on their normal route of descent they will probably come down at puberty. If they have left their normal course they will not descend spontaneously and surgery will ultimately be needed. The best advice is that no action should be taken until the age of 12, or until signs of puberty are first seen if this should be earlier. The boy should then be given a course of intramuscular injections of chorionic gonadotrophin (500 international units twice weekly). If the testicles have not descended in three months on such treatment operation is advisable. Treatment will not in this case be

wasted, as it is now generally admitted that the increase in size and blood supply of the imprisoned testicles improves their chance of ultimate survival in the scrotum.

I do not know the proportion of cases in which spontaneous descent occurs at puberty, but it is certainly high. In such cases endocrine treatment may be regarded as a test of their capacity to descend. It is incorrect to state, as some do, that endocrine treatment is no more than a test and that all cases which can be cured by these means would recover spontaneously.

D.D.T. Paint

Q.—Can D.D.T. be mixed effectively with paint or distemper?

A.—D.D.T. can be incorporated in various ways in white-wash, distemper, and paint. However, where "drying" oils are present (as in paint or washable distemper) the insecticidal action of D.D.T. is much reduced, presumably because it is then much less available to poison insects. Therefore they can, without harm, remain much longer in contact with D.D.T.-paint or D.D.T.-distemper than with the residue of an ordinary spray deposit. There seems to be no advantage whatever in incorporating D.D.T. into distemper or paint, since it does not seem to be any more persistent in this form and it is certainly much less efficient.

Excessive Coffee-drinking

Q.—Can you refer me to some authoritative study of the ill effects of excessive coffee-drinking?

A.—The most authoritative discussion of coffee-drinking is published in the *Archiv für experimentelle Pathologie und Pharmakologie* (1938, 190, 118). The discussion is opened by no less an authority than Straub, and he is followed by Eichler, Stieve, Stepp, and Flury. There is a recent paper by Roth, Ivy, and Atkinson in the *Journal of the American Medical Association* (1944, 126, 814), dealing with caffeine and peptic ulcer, in which evidence is presented that 70% of ulcer patients found that coffee and tea increased their symptoms.

Making Soft Toys Aseptic

Q.—What is the best method for disinfecting unbleached wool and fur fabric used in the manufacture of soft toys? Would the application of antiseptic powder be satisfactory?

A.—The best way to treat unbleached wool, fur fabric, or toys made of these materials, in order to render them aseptic, would be to sterilize with steam, in the same way as surgical material and instruments are sterilized. The introduction of antiseptic powder would not be nearly so satisfactory. All such powders are irritant and might produce dermatitis in susceptible individuals; and it would certainly be undesirable to give children toys impregnated with materials of this kind.

High Altitudes and Duodenal Ulcer

Q.—A man in his middle fifties has had three attacks of duodenal ulceration, with two severe haematemeses. He now proposes to live on an altitude of about 8,000 ft. (2,400 m.), practically on the Equator. What effect, if any, will this have on the coagulation of the blood? Is it true that a great many people living under these conditions become "nervy" and "jumpy"? Finally, are such conditions suitable for children?

A.—Duodenal ulcer is a chronic complaint always liable to relapse unless continued care is taken. Although this patient is said to have had only "three attacks of duodenal ulceration," the fact that he has had two dangerous haematemeses suggests that the prognosis is unsatisfactory. Unless this patient can be in a position to look after himself and his diet in the best possible way further haemorrhage can be expected. He should bear in mind that in the last war he would have been considered unfit for service anywhere overseas.

Questions about the effect of altitude upon the coagulation of the blood (which will be unaltered) are of little moment compared with those about the possibilities for diet in his new surroundings. Even more important are the medical and hospital facilities provided. The patient may well become "jumpy" and "nervy" if he is living some hundreds of miles

away from the nearest hospital and blood-transfusion apparatus. Extra oxygen is not usually required below 10,000 ft. (3,000 m.), but 8,000 ft. is not far below this and considerable constitutional upsets are to be expected. These will be noticed on arrival, before the individual has become acclimatized, and again after a long stay at that height. Lethargy, jumpiness, and flatulent dyspepsia may be anticipated. Conditions at 8,000 ft. cannot be recommended for children.

Erysipeloid

Q.—What is the most satisfactory form of treatment for a very troublesome erysipeloid condition common in butchers and fishmongers, known as "fish-handlers' disease"?

A.—Erysipeloid, an infection due to *Erysipelothrix rhusiopathiae*, responds dramatically to intramuscular penicillin within a matter of 48 hours. I have seen good response to as small a dose as 100,000 units.

Treatment of Ophthalmia Neonatorum

Q.—What is the recognized modern treatment for ophthalmia neonatorum?

A.—The classical methods of treatment consisted essentially of ceaselessly washing away all the pus from the infected eye to prevent it from damaging the cornea, and waiting for spontaneous healing, which generally took some weeks. In contrast, the modern methods of treatment deal with the infection primarily. Two alternative procedures are available:

(1) *Sulphonamide Therapy.*—Employed locally the sulphonamides are useless in ophthalmia neonatorum, as they are inactivated by pus and breakdown products of the tissues; given by mouth they are highly effective. When the baby is first seen a swab of the pus is taken both for a smear preparation and for a culture. The eyes are then irrigated with bland lotion, such as half-normal saline solution at room temperature: 1% atropine sulphate drops and drops of medicinal paraffin are instilled as a routine measure, and half a tablet of sulphamezathine (0.25 g.) crushed into powder is given by mouth in a teaspoonful of water or milk. Sulphamezathine administration is continued in doses of 0.125 g. every four hours, day and night, until 48 hours after a clinical cure is obtained. Local treatment consists in three-hourly irrigation with a saline solution during the first day in cases with profuse discharge; as a rule there is no need for further irrigation on the subsequent days. After irrigation medicinal paraffin is instilled to prevent the lids sticking together. Atropine is instilled three times daily in cases with corneal haze or ulceration.

With this treatment swelling of the lids generally subsides within 12 hours after admission; purulent discharge disappears within 24 hours, so that a threatening purulent ophthalmia becomes a simple conjunctivitis giving no anxiety. The eyes are either dry or very nearly so within 72 hours. Some 40% of all affected babies show complete clinical cure within three days, and 90% within eight days. Resistant cases are only relative failures with a somewhat prolonged course which, however, does not give rise to anxiety, as there is conjunctivitis rather than purulent ophthalmia. Isolated cases of complete resistance to sulphonamides have, however, been observed. Babies tolerate oral sulphonamides well. Nothing is gained by using doses smaller than those indicated, and it is important to continue the treatment for 48 hours after clinical cure, as too early suspension may lead to a relapse.

(2) *Penicillin Therapy.*—Unlike the sulphonamides, penicillin remains effective in the presence of pus. It can therefore be used as a local agent, and has one other advantage in that cure is even more rapid and dramatic. For the present, however, treatment is rather exacting, and it is not yet as standardized as oral sulphonamide therapy.

In the use of penicillin, concentration and frequency are all important. The present routine procedure consists of the following stages: (1) A swab of the pus is taken for bacteriological examination. (2) The eye is then irrigated with half-normal saline at room temperature to wash away pus. (3) A nurse seated on a chair takes the baby on her lap, and another nurse is responsible for putting into the eye two drops of penicillin, 2,500 units per ml., every minute. (4) Pus does not tend to re-form while this treatment is in progress. Any secretion can readily be wiped off with pledgets of cotton-wool.

is to be created. In view of the fact, however, that such a Government medical officer would be required to accept liabilities such as night calls and other demands which are the common lot of the private practitioner, and from which the public health medical officer is ordinarily exempt, he should receive an allowance of £10 a month in addition to his salary.

Patients' Payments

General practitioner service—and also dentistry, optical services, drugs, and surgical appliances, and the services of recognized health personnel—should be paid for, in the commission's view, by the patient himself up to a prescribed maximum each year. It is suggested that on the first £500 of his income he should pay up to 2% per annum (with a minimum of £2) for any medical services in the category stated which he or his family may require. On the second £500 he should pay at the rate of 2½%, on the third £500 at the rate of 3%, and so on. Thus with an annual income of £200 the individual would have to spend on these medical services a sum of £4 before he became eligible for State benefit; with an income of £600 he would pay £12 10s.; with an income of £1,000 he would pay £22 10s. Above the maximum any additional cost would be met from the Government fund. It would be required that the individual should not only have incurred this expenditure, but should actually have met it. The benefit of the arrangement is that no individual would be called upon to bear an undue financial burden for sickness in any one year. The medical expenditure of the whole family would be counted towards the respective maxima so that married men with large families would receive more aid than bachelors or childless couples.

The general practitioner would, presumably, be remunerated on a fee-for-service basis, partly from the patient, and, for any amount in excess of the patient's maximum liability, from the State. The Government, in consultation with professional bodies, will lay down certain agreed rates of charge for medical and other services.

Hospitals a State Service

The financial advantages to the general practitioner will be a reduction in the amount of bad debts and in the expense of debt collection, and he may expect an increase of practice because patients would no longer be deterred by the prospect of incurring high cost. On the other hand, since the commission recommends that surgical and medical treatment in hospitals and consultant, maternity, x-ray, and laboratory services should be provided free to all by means of a full-time salaried staff, the general practitioner would find himself excluded from hospitals and maternity homes where he has been accustomed to follow his patient. The commission lays it down that patients who do not wish to accept the services of the salaried hospital consultant staff should pay the full economic rates as well as their private practitioner's fee. Two members of the commission, including Dr. Burnett, put in a demurrer here, urging that maternity homes should remain open to general practitioners. But the commission's recommendation is that cases in maternity homes should be attended by salaried obstetricians assisted by midwives, who will be responsible for normal deliveries, with consultant obstetricians and gynaecologists within call.

Apparently the practice of general practitioners of following their own cases into hospitals has raised difficulties in Southern Rhodesia, where the Government owns and runs nearly all the nineteen hospitals, and with three or four minor exceptions all the maternity homes. Entry to a Government hospital—at least in Salisbury, the capital—has come to be regarded as the right of every general practitioner, a state of affairs which is said not to obtain in the hospitals of any other Government of the Empire. As beds become vacant, the general practitioner's private cases are nursed under his orders by Government nurses, and medicines ordered are supplied from Government stocks on Government funds, and for all this the patient pays the normal fee to his private doctor, and to the Government he makes only a sub-economic payment. It is stated that practitioners attending the hospitals make control difficult, and in fact the Government hospital

becomes a private nursing home for general practitioners have no responsibility for its efficient and economical run. The commission finds that operations requiring a high degree of skill and experience are frequently performed by practitioners with little of either. Nearly half the demand on overworked out-patient nursing staff is taken up by patients who have an appointment with their private doctor in department.

The commission therefore recommends that the privilege of general access be withdrawn, and that a full-time salaried including consultants, be set up, their services to be available to the whole population. It is considered that it might be possible to appoint a sufficient number of whole-time consultants to deal with most of the medical and surgical cases which need hospital attention.

Administration

A very large part of the report is occupied with the discussion of what are called "health" promotive services—"nutrition, housing, the school medical service—as well as with preventive services, such as sanitation, water supplies, and malaria control. On the administrative side the commission recommends the setting up of a national health board to form long-term plans and generally to advise the Government on all matters of health. A board of nine is recommended including two medical members, who would probably be appointed on the nomination of the B.M.A. Branches. It is proposed that the country be divided into five regions, each with a council to advise, plan, and co-ordinate, and the regions into areas—larger than the present municipalities—with committees having both advisory and executive functions.

The salary proposed for the chief medical officer "Secretary for Health" as he would be called—would be immediately under a Minister of Health is £2,250. To him would be directors of public health and of research receiving £1,750, rising to £2,000. Medical inspectors of schools and regional medical officers would receive £1,500, rising to £1,750, senior research officers and medical officers in charge of laboratories, £1,300 to £1,500, and area medical officers—the rank and file of the service—£750, rising to £1,000 instead of their present £600, rising to £900.

Another recommendation is that medical officers should be afforded facilities by way of generous study leave for acquiring additional qualifications. There is no medical teaching in the colony, nor is there likely to be one for many years to come. It is also suggested that a panel of professional men be appointed at the High Commissioner's office in London to scrutinize the qualifications, experience, and suitability of candidates for medical employment in Southern Rhodesia.

HEARD AT HEADQUARTERS

The Civil Service

The Lord Chancellor in the Second Reading debate in the House of Lords said that even if a doctor's entire salary paid [by the State] that did not involve his becoming a Civil Servant. A good deal depends, of course, upon the meaning attached to the word "mere." The Chief Medical Officer of the Ministry is not a "mere" Civil Servant. But "Civil Service" as defined by Murray is a collective term for a non-warlike branches of the public administrative service of the State, including, among others, the educational departments which the State controls. Thus all teachers in Schools are Civil Servants, mere or otherwise. It is difficult to see how the term would be inapplicable to doctors employed in a whole-time salaried service.

The Deaf not Satisfied

The friends of the deaf, as represented by their National Institute, seem to be by no means satisfied with Lord Walsingham's statement that in 1948 everyone who needs it will receive aural aid free of charge and with free servicing. Lord Walsingham

Government Whip in the House of Lords, seemed rather to suggest that this, with treatment for those who would benefit by it, was all that the Government could be expected to do on behalf of this hitherto largely neglected class of the community. It was pointed out to him that for the deaf and dumb a valve amplifier will be of no use at all, and that for many others of the deaf the old-fashioned ear trumpet would be more suitable than an electrical aid. More important, according to friends of the deaf, is the provision of educational facilities for the deaf and dumb.

The Refraction Service

A meeting of representatives of the Ophthalmic Group Committee of the B.M.A. with sight-testing opticians has led to the appointment of a joint committee consisting of five representatives on each side, with an officer of the Ministry of Health as chairman. This is to be known as the Eye Services Committee, and its purpose is to consider the status, scope of work, and designation of opticians in the final form of the national ophthalmic service, and the criteria, if any, to be applied in the selection of opticians for appointment. Three meetings have already been held, and a fourth has been fixed for the beginning of November. At the first meeting it was provisionally agreed to recommend to the parent bodies that the scope of the work of the opticians, subject to the overriding responsibility of the ophthalmologist, should be to examine by refraction and otherwise the eyes of persons referred to them by the ophthalmologist and to report back to him. The second and third meetings were occupied with a discussion of the personal arrangements in an eye services clinic.

Mr. John Foster gave to the Ophthalmological Section of the Royal Society of Medicine the other evening an interesting account of his tour of eye service clinics in France and Switzerland. In Switzerland—that remarkable country where even the street cleaners smoke cigars—the doctors do refraction, but not, as here, because patients come to them on account of headaches. Apparently they do not have headaches in Switzerland: there people come for the improvement of their sight.

Everlasting Fees

The General Practice Committee had a heavy mass of work before it at its first meeting of the session. An agenda of 34 items seemed to include an unusual number of questions relating to fees, involving most difficult and detailed consideration. Thus there were questions of the fees payable to civilian medical practitioners called upon to examine military personnel on release from service; fees for administration of anaesthetics by practitioners employed on a "per case" basis by local authorities; fees for the treatment of unaccompanied children under the Government evacuation scheme (children who have no suitable homes to which to return); fees for Admiralty surgeons and agents; fees for life assurance examinations; fees for examination of volunteers for the Women's Land Army; fees for the examination of dependants of airmen proceeding over-seas; fees of medical officers to emergency training colleges for teachers; and finally—the constable bringing up the rear—fees for the treatment of members of the police force. The members of the committee must, as Mercutio says in *Romeo and Juliet*, "straight dream on fees."

At the T.U.C.

Very few resolutions touching on health services are on the agenda of the Trades Union Congress at Brighton. The chief is a motion by the Women Public Health Officers' Association calling attention to the widespread and serious shortage of maternity beds in hospitals and urging the Ministry of Health to recruit qualified midwives for work in maternity wards on a non-resident shift basis, to provide increased facilities for training pupil midwives, and to employ State registered and assistant nurses for nursing in maternity wards, thus enabling qualified midwives to concentrate on confinements.

The National Union of Vehicle Builders is opposed to workers' being compelled to submit themselves to medical examination by firms' doctors, when seeking employment,

without the right of appeal to an independent tribunal, and declares that in all cases of adverse medical reports the workers should be informed of the grounds upon which the report rests. The Associated Society of Locomotive Engineers and Firemen wants to instruct the General Council to press the Government to introduce an efficient industrial health service to cover all industries; and the Medical Practitioners' Union is urging that practitioners under the National Health Service adjudged to be guilty of faults incurring removal from the Service should have full right of appeal to the courts.

THE DAIN FUND

REPORT OF THE TRUSTEES

Inaugurated in 1936 to honour Dr. H. Guy Dain, of Birmingham, for his outstanding services to the medical profession, the Dain Testimonial Fund, consisting of £4,564 4s. 7d., was completed in 1939 and would have been presented to Dr. Dain at the Panel Conference that year but for the outbreak of war. The formal presentation, however, is to be made at the Panel Conference, 1946.

Dr. Dain intimated that he wished his Testimonial to be devoted to the assistance of the sons and daughters of medical practitioners in need of financial help for educational purposes. The importance of this work and of its claims upon the interest of members of the profession generally needs neither emphasis nor justification, but it tends to be forgotten amid the many claims upon the time and generosity of members of a busy profession.

The interest accruing from the investments of the Fund together with gifts received since its inception (£175 19s.) has enabled the Trustees to do valuable work. Of the eighteen applications received, assistance has been given to eight cases by grants amounting to a total of £755 13s. These grants varied from a single sum of £30 to grants of £100 per annum for a period of four years. In two further cases the Dain Fund is sharing the financial responsibility with the Royal Medical Foundation of Epsom College and the Ladies' Guild of the Royal Medical Benevolent Fund. To certain applicants it has not been possible to give assistance at all owing to other cases of greater need or through lack of funds. Each application is considered in detail, and if assistance is not possible from the Dain Fund every effort is made to obtain help from other sources. In several cases this has been possible, and the following funds have taken over the responsibility: the Medical War Relief Fund, the Medical Benevolent Society of Birmingham, the Royal Medical Benevolent Fund, and local Panel Committee Benevolent Funds.

Almost without exception applications for assistance have the same history: the early death of a practitioner leaves a widow with heavy financial commitments in the education of her children. Cases of this kind which do not come to the notice of the Trustees of the Fund are no doubt numerous, and educational charges continue to be met at the price of strain and overwork of the parent and anxiety to the student. In the cases which do come before the Trustees, personal sacrifice and the finest adjustment of domestic expenditure leave a balance which cannot be met without assistance. If this is not forthcoming, it may mean the abandonment of a career, and the career is often that of medicine. Though the Fund is dedicated to assistance in education generally, in many cases assistance is sought for the continuance of medical education, or for preparation for it, many of the children desiring to follow a family tradition of the practice of medicine. The following cases are of interest:

Case A.—A medical practitioner died in 1939 leaving two young sons. The widow appealed for assistance for both boys. The elder, however, was awarded a scholarship at a public school in 1939, the younger obtaining a similar scholarship in 1940. Assistance was requested for the younger boy during the intervening year and a grant was approved.

Case B.—A medical practitioner was wounded so severely in the 1914-18 war that eventually he had to give up work altogether. He made application to the Dain Fund for assistance towards the education of his daughter. The Trustees awarded a grant, and

the same year his daughter obtained her School Certificate. The following is an extract from this doctor's acknowledgment: "Will you very kindly convey to the Trustees of the Dain Fund my deep appreciation of their generous help in thus enabling B. to complete her school education? It is not possible to find words adequate to express one's gratitude."

Case C.—The early death at the age of 39 of a general practitioner, while he was still repaying a loan for a share in a practice, left his wife and son in extreme financial difficulties. The widow did private nursing, from which she earned about £50 per annum, to increase her very small private income. In 1941, nine years after her husband's death, she developed carcinoma and underwent a major operation. At this time an appeal was made to the Ladies' Guild of the Royal Medical Benevolent Fund for assistance in the education of her son. The fees over a period of four years were shared by the two funds. The boy did well and passed his School Certificate in 1945.

Case D.—The widow of a medical practitioner was left with a son and daughter aged three and six years at the time of their father's death. She had a very small income, but managed to complete their school education. At the time of the application her daughter was doing secretarial work and could just manage to keep herself with a little help from her mother; the boy had won a scholarship at a London medical school and was a pre-medical student evacuated to a town in the Home Counties. His mother had difficulty in finding sufficient money to cover expenses, chiefly in connexion with his board and lodging, and made an appeal for assistance. The Trustees of the Fund awarded six grants to her for these expenses during his training. He qualified M.B., B.S.(Lond.), and after holding two house appointments is now serving with the R.A.M.C.

Case E.—A general practitioner died in 1929 leaving a widow, two daughters, and one son. In 1940 the boy obtained a scholarship at a public school from the Lent Term, 1941. Application was made for assistance in the fees for his private school. A local benevolent society agreed to contribute, and a similar grant was made from the Dain Fund until he entered the public school.

Case F.—A general practitioner died suddenly leaving a widow and five children. The three elder children were self-supporting, but the two younger were dependent on their mother. A boy, the fourth child, had started his training as a dental student, and in order to enable him to continue his studies an application was made to the Fund for financial assistance. Information was obtained regarding his ability, and a grant for four years was approved in 1946, the continuation of the grant being subject to a satisfactory annual report from the dean of the dental school.

The Trustees feel that this opportunity should be taken to bring the aims and objects of the Dain Fund once more to the notice of the profession, and to recommend its claims, not only as testimony of appreciation of the efforts over many years of one of its most active members, but also as a means of assisting some of the less fortunate children of medical practitioners.

Gifts to the Fund should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

September, 1946.

MEDICAL EXAMINATIONS FOR LIFE ASSURANCE PURPOSES

The number of inquiries which have recently been received indicates that there is at the present time considerable uncertainty in the minds of practitioners about the policy of the Association on the question of the fees which should be paid for medical examinations in connexion with life assurance.

In accordance with a recommendation of the A.R.M. last July the Association is now discussing with the Life Offices Association the basis for a new agreement providing for the payment of fees substantially higher than those now paid. It is anticipated that agreement will be reached on this question very shortly. In the meantime practitioners are recommended to accept payment for such examinations at the current rates.

RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Dr. R. H. Dobbs, at 135, Harley Street, W.1; Charles Donald, F.R.C.S., at 66, Harley Street, W.1 (Langham 2878); D. L. Griffiths, F.R.C.S., at 14, St. John Street, Manchester, 3 (Blackfriars 9598). *Corrected announcement:* Dr. W. Lindsay Neustatter, at 128, Harley Street, W.1 (Welbeck 3868 and Beaconsfield 723).

Correspondence

Inefficiency of Government Schemes

SIR.—A very large number of people believe the B.M.A. to be the strongest trade union in the country. They are wrong of course, but the belief is firmly held. An even larger number hold the medical profession in high esteem. In doing so they are, up to the present, probably right. Let us be very careful that we do not jeopardize that esteem. We have all seen more than enough of strikes, go slow, more pay, less work, and so on. If we join the sorry ranks of self-first-and-the-country-nowhere merchants, we shall by our example encourage them to further excesses.

Would it not be a better and wiser policy to accept the offer of the Minister of Health, while at the same time we insert in every paper in the country announcements explaining that we consider the offer unjust, inadequate, and dishonest? At the same time, and in the same announcements, it would be well to add that the majority of the doctors in this country are very strongly opposed to taking part in any National Health Service sponsored by the shoddy, incompetent crew who rule us at present.

Our first duty is the safeguarding of the health of the community: the safeguarding of our incomes is a secondary consideration. We are amply justified in stating that we will not take part in any gamble in which the national health is at stake. That would not be a strike, but just ordinary prudence.

When we consider the mess that the present Government has made of foreign affairs, coal, housing, food, and stock breeding, it becomes obvious that any scheme emanating from them is almost certainly foredoomed to failure.—I am, etc.,

London, W.9.

JAMES GOSSIP.

"Basic Salary"

SIR.—To differentiate between "full-time salary" and "basic salary" may be good tactics for a politician, but we must at all costs avoid the trap. It should be clearly recognized that when the Minister of Health says "basic salary" he must really mean "basic contract." The contract inevitably goes with the salary, and while it is impossible to find any genuine reason for the Minister's anxiety to foist a salary upon us it is easy to see why he might desire to force us into making a basic contract with him. Given such a contract, even though it may be the source of only part of the doctor's income, the doctor becomes utterly dependent on the good will of the Minister for his ability to seek a livelihood. A capitation fee leaves the hiring and firing of doctors where it naturally belongs—with the patient. If before we can make contracts with individual patients we must first make, and keep valid, a contract with the Minister, then he is assuming legally a quite unnatural overriding power to hire and fire us. This simple and frightening fact remains true no matter how small a proportion of our incomes is offered as a "basic salary."—I am, etc.,

West Bromwich.

D. SAKLATVALA

Medical Unemployment

SIR.—It is apparent from the self-satisfied tone of "Rather Disgusted" (Sept. 21, p. 85) that he has not served with the Forces. I can assure him that it is not due to lack of initiative on the part of many demobilized doctors that they are unable to obtain work either in hospitals or in private practice. I have answered many advertisements in order to buy a practice or obtain an assistantship with a view to partnership, and in many cases have failed even to get a reply from the advertiser. Many of my colleagues who served their country in the Forces have applied for various hospital posts but have been unable to obtain them; and what is the pay when such a post is obtained?—about £100–£350 a year. (I know there are a few "super-scale" posts up to £2,000 a year, but these are very few and far between.) This is not a rosy picture for a man who may have a wife and family to keep; and who can blame him for looking forward to the day when medicine will be taken over by the State and doctors assured of at least a living wage?

My answer to "Rather Disgusted" is that he should sell his practice and house, join one of H.M. Services and on demobilization see what it is like trying to obtain a suitable post. I consider myself luckier than most as I can afford to wait a little while and to purchase a practice or a part share: but as yet I have been unable to find one.—I am, etc.,

"ONE OF THE MANY UNEMPLOYED."

SIR,—With reference to the recent correspondence from ex-Service and rejected doctors, I advertised for help a short time ago and had about thirty applicants. My offer was £500 basic salary, sleep in, 3/4 share of all increase in practice over present figure—I have been ill for a considerable time and can only do a portion of the work as yet—partnership in 12–24 months without capital payment if results justified it.

I think this is a reasonable offer, but one after another has turned it down for some reason or another. In view of the outcry of "unemployed doctors" this has given me furiously to think.—I am, etc.,

London, W.C.

"PUZZLED."

Trials of a Job-hunter

"DELTA" writes: For the past three months I have been, like many hundreds of other doctors, "job-hunting," and must have written a score of applications, enclosing testimonials, etc., in answer to advertisements in your columns. In only a small minority of cases have I been honoured by the courtesy of a reply. In the vast majority the applications—and in two cases reply-paid telegrams—have been completely ignored. If the secretarial staffs of the various hospitals, etc., to which I have written are too overworked to answer even in the negative the masses of applications they probably receive, may I suggest the advisability of their taking on some of us unemployed as additional clerks?

ADDITIONS TO B.M.A. LIBRARY

The following *Supplements* of the Scandinavian journal *Acta Radiologica* have been placed in the Library of the British Medical Association (the figures in bold type refer to the number of the *Supplement*).

The Roentgen Density of the Cystine Calculus. By Axel Renander 1941, 41.

Beiträge zur Röntgendiagnostik der Otitis Media Acuta. By Sölve Welin. 1941, 42.

Hystero-Salpingo-Pelviographie. By Sven Roland Kjellberg. 1942, 43.

Experiments with Mammalian Sarcoma Extracts in regard to Cell-free Transuission and Induced Tumour Immunity. By Carl Krebs, Oskar Thordarson, and Johannes Harbo. 1942, 44.

The Muscular Build and Movements of the Stomach and Duodenal Bulb. By Johan Torgersen. 1942, 45.

Studies on Protein Metabolism in the Cells of Epithelial Tumours By Torbjörn Caspersson and Lars Santesson. 1942, 46.

Die Urographie bei der Nierentuberkulose. By Olle Olsson. 1943, 47.

Cancer of the Lip. By Bertil Ebenius. 1943, 48.

*Studien über einige Biologische Wirkungen der Röntgen- und γ -Strahlen. Insbesondere am *Phycomyces Blakesleeanus*.* By Arne G. Forsberg. 1943, 49.

Radiotherapy in Actinomycosis. By Eivind Stokkeland. 1943, 50.

The Value of the Barium Enema in the Diagnosis and Treatment of Intussusception in Children. By Jens Munck Nordentoft 1943, 51.

The Radiosensitivity of the Bone Marrow. By Torfinn Denstad 1943, 52.

Renal Tuberculosis and Roentgenologic Examination. By Ragnar Steinert. 1943, 53.

Untersuchungen über die Röntgennahbestrahlung. By Sven Hultberg. 1943, 54.

Studien über die Kumulative Wirkung der Röntgenstrahlen bei Fraktionierung. By Magnus Strandqvist. 1944, 55.

Cerebral Angiography with Perabrodil (Carotis Angiography). By Arne Engeset. 1944, 56.

Cancer of the Breast, with Special Reference to the Results of Different Methods of Treatment. By Sture Rödén. 1944, 57.

Urethrocytography in the Male with Special Regard to Micturition. By Nils P. G. Edling. 1945, 58.

They are all in English with the exception of Nos. 42, 43, 47, 49, 54, and 55, which are in German.

Association Notices

COMMITTEES OF SPECIAL GROUPS WITHIN THE ASSOCIATION

As a result of the elections held recently within the membership of Special Groups of the British Medical Association, the following Group Committees have been appointed for the period 1946–9:

FULL-TIME NON-PROFESSORIAL MEDICAL TEACHERS LABORATORY AND RESEARCH WORKERS GROUP COMMITTEE

Dr. C. J. C. Britton, London.
Dr. W. R. M. Morton, Cambridge
Dr. A. J. Rhodes, London.
Dr. W. Susman, Manchester.
4 vacancies.

ORTHOPAEDIC GROUP COMMITTEE

Mr. B. H. Burns, London.
Mr. V. H. Ellis, London.
Mr. C. G. Irwin, Newcastle-upon-Tyne
Mr. S. T. Irwin, Belfast.
Mr. S. A. S. Malkin, Nottingham.
Mr. A. Miller, Glasgow.
Mr. G. Perkins, London.
Prof. Harry Platt, Manchester
Mr. Philip Wiles, London.

PATHOLOGISTS GROUP COMMITTEE

Prof. G. R. Cameron, London.
Prof. D. F. Cappel, Glasgow.
Dr. C. E. Dukes, London.
Dr. S. C. Dyke, Tettenhall.
Dr. R. W. Fairbrother, Manchester
Dr. J. G. Greenfield, London.
Dr. R. J. V. Pulvertaft, London.
Dr. A. F. S. Sladden, Swansea.
Sir Lionel Whitby, Cambridge.

PHYSICAL MEDICINE GROUP COMMITTEE

Dr. L. D. Bailey, Northwood.
Dr. P. Bauwens, London.
Dr. C. W. Buckley, Derby
Dr. J. B. Burt, Bath.
Dr. F. S. Cooksey, Epsom.
Dr. W. S. C. Copeman, London.
Dr. J. Cowan, Manchester.
Dr. J. W. T. Patterson, Droitwich.
Sir Morton Smart, London.
Dr. W. S. Tegner, London.

1 member to be appointed by Radiologists Group Committee
1 member to be appointed by Spa Practitioners Group Committee.

PSYCHOLOGICAL MEDICINE GROUP COMMITTEE

Dr. H. Crichton-Miller, London.
Surg.-Capt. D. Curran, London.
Lieut.-Col. H. V. Dicks, London.
Prof. D. K. Henderson, Edinburgh.
Lieut.-Col. P. K. McCowan, Dumfries.
Dr. W. G. Masefield, Eastbourne.
Lieut.-Col. A. A. W. Petrie, Sutton.
Dr. J. R. Rees, London.
Dr. W. Rees Thomas, St. Annes-on-Sea.

RADIOLOGISTS GROUP COMMITTEE

Dr. J. F. Brailsford, Birmingham.
Dr. S. Whately Davidson, Newcastle-upon-Tyne.
Mr. J. L. A. Grout, Sheffield.
Dr. M. H. Jupe, London.
Dr. A. B. Maclean, Glasgow.
Dr. R. Boulton Myles, Worthing.
Dr. Ralston Paterson, Manchester.
Dr. S. Cochrane Shanks, London.
Dr. C. G. Teall, Birmingham.

SPA PRACTITIONERS GROUP COMMITTEE

Dr. W. Edgecombe, Harrogate.
Dr. R. G. Gordon, Bath.
Dr. L. C. Hill, Bath.
Dr. A. R. Neligan, Droitwich.
Dr. L. J. Prosser, Harrogate.
Dr. W. Yeoman, Harrogate.
1 vacancy.

GROUP OF ANAESTHETISTS

A meeting of the recently formed Group of Anaesthetists within the Association will be held at B.M.A. House, Tavistock Square, W.C.1, on Friday, Nov. 1, 1946, at 2 p.m. All members of the Association who are engaged predominantly in the practice of anaesthetics are eligible for membership of the Group and both those anaesthetists who have already applied for membership, and those who now contemplate joining, are invited to attend.

The agenda will consist of (a) the election of a chairman; (b) consideration of the size of the Group Committee; and (c) a general discussion on the work of the Group.

(Sgd.) CHARLES HILL,
Secretary.

Middlemore Prize

The Middlemore Prize consists of a cheque for £50 and an illuminated certificate, and was founded in 1880 by the late Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize in the year 1947 to the author of the best essay on: "The Aetiology and Treatment of Chronic Iridocyclitis." Essays submitted in competition must reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, on or before Dec. 31, 1946. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1947.

The Katherine Bishop Harman Prize

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1947. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child-bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1947, but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine. The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, at B.M.A. House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1946.

Diary of Central Meetings

OCTOBER

30. Wed. Postgraduate Subcommittee: (Film Committee), 2 p.m.

NOVEMBER

6. Wed. Ordinary meeting of Council, 10 a.m.
8. Fri. G.M.C. Committee, 2 p.m.
19. Tues. Undergraduate Subcommittee: (Film Committee), 2 p.m.

Branch and Division Meetings to be Held

BOURNEMOUTH DIVISION.—At Burlington Hotel, Owls Road, Boscombe, Friday, Nov. 8, at 7.30 p.m. for 7.45 p.m. Annual dinner.

BRIGHTON DIVISION.—At Royal Pavilion, Brighton, Tuesday, Oct. 29, 8.30 p.m. Annual general meeting. Election of officers, etc.

Meetings of Branches and Divisions

COVENTRY DIVISION

An ordinary general meeting of the Division was held in the Coventry and Warwickshire Hospital on Oct. 8. Twenty-three members were present. A discussion on the relationship between the industrial medical officer and the general practitioner was opened by Dr. MACDONALD, who said that the joint task of the I.M.O. and the G.P. was to ensure the health and the

earning capacity of the worker. He outlined his work in an up-to-date surgery and spoke of his close relationship with the labor bureau. There was difficulty in drawing the line between treatment which could be given at a factory and that which should be given by the worker's own doctor. The worker requiring physiotherapy could be given it at work, which was a help to the man on piece work.

Others taking part in the discussion were Drs. Wright, Catto, Coghill, Turner, Clayton, and Gallagher. It was considered that the I.M.O. wished an employee to see a consultant at hospital or otherwise, the I.M.O. should consult the worker's own doctor.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Prof. A. Lipschutz: *Mon.*, 3.30 p.m., The Tumorigenic Action of Steroids and its Implication for the Problem of Cancer *Tues.*, 3.30 p.m., The Antitumorigenic Action of Steroids; *Fri.*, 3.30 p.m., The Steroid Balance and the Antitumoral Autodefence

ROYAL SOCIETY OF MEDICINE

Lloyd Roberts Lecture.—*Mon.*, 3 p.m. Field Marshal Viscount Montgomery of Alamein, G.C.B., D.S.O.: Morale—with particular reference to the British soldier. Admission will be by ticket only
Section of Odontology.—*Mon.*, 5.30 p.m. Presidential address by Prof. H. Stobie: The role of dentistry in Medicine.

Section of Otolaryngology.—*Fri.*, 10.30 a.m. (Cases at 10 a.m.) Presidential address by Mr. H. V. Forster: Otolaryngology in school-children and Child Welfare. A discussion will follow.

Section of Laryngology.—*Fri.*, 2.30 p.m. Presidential address by Mr. Norman Paterson: Reminiscences and reflections. Film by Mr. Lionel Colledge: Laryngectomy.

Section of Anaesthetics.—*Fri.*, 7.15 p.m. Meeting to celebrate the centenary of the first public administration of an anaesthetic. Reception by Sir Gordon Gordon-Taylor. 8.15 p.m. Presidential address by Dr. E. S. Rowbotham: A hundred years of anaesthesia.

BIOCHEMICAL SOCIETY AND SOCIETY FOR GENERAL MICROBIOLOGY.—At London School of Hygiene and Tropical Medicine, Keppel Street, W.C.2, *Sat.* (Nov. 2), 11.15 a.m. Joint discussion: Quantitative Biochemical Analysis by Microbiological Response.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—*Fri.*, 8.3 p.m. Prof. H. V. Dicks: Role of the Family Doctor in Mental Hygiene.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.—*Mon.* 8.30 p.m. Discussion: Symptomatology and Treatment of Intervertebral Disks. To be introduced by Mr. Norman Dott and S. Charles Symonds.

PADDOINGTON MEDICAL SOCIETY.—At St. Mary's Hospital, W., *Tues.* 9 p.m. Dr. G. B. Mitchell-Heags: Penicillin in the Treatment of Skin Diseases. Cases will be shown.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS, 58, Queen Anne Street, W.—*Fri.*, 5 p.m. Prof. J. Chassar Moir: Application of Radiology to the Diagnosis of Cephalo-pelvic Disproportion.

WEEKLY POSTGRADUATE DIARY

BLACKPOOL: VICTORIA HOSPITAL.—*Thurs.*, 8 p.m. Mr. Buckley: Genito-Urinary Infections.

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Edinburgh Royal Infirmary, *Tues.*, 5 p.m. Dr. A. C. P. Campbell: Cellular Defence.

LONDON SCHOOL OF DERMATOLOGY, 5 Lisle Street, Leicester Square, W.C.2.—*Tues.*, 5 p.m. Sir Archibald Gray: Sarcoidosis. *Thurs.* 5 p.m. Dr. J. L. Franklin: Lichen Planus and Lichenoid Eruptions.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

FITZGERALD-O'CONNOR.—On Oct. 12, 1946, at Helenshowe, Abingdon, Berk to Dr. and Mrs. G. Fitzgerald-O'Connor, a fourth child and third son, Alexander Francis.

KENNEDY.—On Oct. 3, 1946, at Redhill, to Barbara (née Singleton) and John Kennedy, D.O.M.S., a son—Richard John.

WOOLLEY.—On Oct. 18, 1946, at the Queen Mary Nursing Home, Derby, Vivien, wife of Dr. M. J. S. Woolley, of Oak Dene, Duffield Road, Derby, a daughter.

MARRIAGE

ESSON—WALSH.—On Oct. 12, 1946, at St. Andrew's Parish Church, Ashton-on-Ribble, Preston, Lancs, by Canon F. A. Addison, M.A., Mr. William E. Eson, of Singapore and Penang, to Dr. Isabel Taylor Walsh, of Redcliffe, Ashton-on-Ribble, Lancs.

DEATHS

GREENSHIELDS-DAVIS.—On Oct. 10, 1946, the result of a road accident some where in Austria, Geoffrey Richard, aged 24 years, Captain 7th Hussars (Queen's Own), third year medical student at Edinburgh University. Beloved only child of Dr. Gwendolyn G. Newth and stepson of Dr. A. A. F. Newth, senior school medical officer, Nottingham.

MURRAY.—On Oct. 13, 1946, at Scafield House, Banff, Andrew Brown Murray, M.B., C.M., beloved husband of Bertha Stevenson.

NUTTALL.—On Aug. 18, 1946, William Nuttall, M.B., Ch.B., of Thornton near Blackpool (late Little Lever, Bolton), aged 83.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 2 1946

PSYCHICAL SEIZURES*

BY

WILDER PENFIELD, M.D., F.R.S., Hon.F.R.C.S.

(From the Department of Neurology and Neurosurgery, McGill University, Montreal,
and the Montreal Neurological Institute)

The statement has been made that in certain types of abnormal behaviour the patients were experiencing "psychomotor seizures," as though the epileptic discharge were capable of creating and elaborating abnormal thought processes. From the point of view of a psychiatrist it is important to know whether this may be true. Is abnormal behaviour ever a manifestation of a continuing epileptic state? Description of the psychical manifestations of certain types of local seizures and of the abnormal post-ictal states that sometimes follow may throw some light on the answer to this question.

Ictus epilepticus, or an epileptic seizure, is a state produced by intense spontaneous neuronal activity. This activity has a tendency to spread throughout the grey matter of the brain with unbridled augmentation. For the duration of the seizure, until exhaustion sets in, ganglion cells seem to be capable of abnormally great functional discharge. Furthermore, a group of cells discharging at this high rate may produce a similar state in adjacent or in connected groups. Thus, a focal epileptic discharge may spread across grey matter like a prairie fire, or it may follow more distant neuronal pathways to other areas of grey matter.

The presence of a focus of increased ganglionic activity may be detected by electro-encephalography between attacks. The increase and the spread associated with each attack are also easily recorded electrographically, and the neuronal exhaustion that follows is indicated by electrical silence. Thus the suggestion of Hughlings Jackson that seizures begin locally receives further verification. The word ictus means seizure; and we may study by electrical methods the inter-ictal state of the focus, the ictal exaltation of metabolic activity, and the post-ictal state of fatigue (Jasper and Penfield, 1943).

The clinical type of seizure depends upon the location of the initial discharge, and the attack should be classified accordingly. For example, twitching of the right thumb signifies discharge in the grey matter of the precentral gyrus where the thumb has its representation for movement. When an epileptic sees moving lights it indicates a discharge in the visual cortex of one occipital lobe. Simple lapse of consciousness without other manifestation may mean discharge in the highest level of functional integration. Any local discharge may spread farther and the seizure become more elaborate, and it may end as a generalized convulsion (grand mal). Such major seizures are apt to look very much alike from case to case if seen in the terminal stage. But the important problem is, Where was the original discharge? That question may be answered by

describing the beginning of the attack or the character of the minor seizure. Do not believe, until proved, the statement that a certain patient's attacks begin in various ways, for it is almost never true. Different stages may be observed or remembered. A sensory aura is not a phenomenon essentially different from a seizure. It is a minor seizure if it goes no further. If it is a prelude it indicates the firing of the fuse that is about to explode a succession of nerve-cell groups.

For the purposes of this discussion it is important to emphasize that during local epileptic discharge, as well as in the subsequent period of fatigue, the involved area is paralysed so far as any useful function is concerned. The thumb which is forced into Jacksonian movement cannot be controlled by the patient unless he holds it with his other hand, which still responds normally to activity of the opposite hemisphere. During a visual seizure the patient sees only the lights that blot out vision. He is blind to all else. The petit-mal attack, or highest level seizure, "blacks out" consciousness for its duration.

Ictus epilepticus may thus produce amazingly selective paralysis. It was the realization of this fact that placed in the hands of Hughlings Jackson a master key which he used to unlock many an anatomical and physiological problem. The ictal paralysis and the post-ictal paralysis may be equally complete. The thumb is paralysed, the eye is blind, or the patient is unconscious for a little time after the explosion is over as well as during the seizure. This is the negative side of a seizure. It is often overlooked in our thinking, and many seizures actually manifest themselves only by the silence caused by this negative state. This is true in general of the complicated functions of speech and thinking. Discharge in one frontal pole produces silence and loss of consciousness. Discharge in Broca's area of the dominant hemisphere produces not speech but cessation of speaking.

Under the heading of motor or sensory seizures the following may be listed: Jacksonian motor, somato-sensory, contraversive without loss of consciousness, masticatory, auditory, vertiginous, visual, olfactory, autonomic. All of these are either sensory or motor, at least at the outset, and sometimes they may be mixed. Two types of seizure may be mentioned which are not strictly sensory, motor, or psychical: unconscious contraversive and illusion of perception.

The unconscious contraversive seizure results from discharge in one frontal pole. It begins with silence—that is, with loss of all consciousness—and it is followed by turning to the opposite side. Illusion of perception results commonly from discharge in the cortex of one temporal lobe. During a seizure of this sort the patient is still aware of his surroundings, but the interpretation of his present experience is altered. The illusion may be that things seen seem to go farther away or

* Extracts from an address, delivered May 17, 1946, at Boston, and June 14, 1946, at Oxford. The complete paper will be published with other addresses in book form to commemorate the opening of the MacLean Hospital Laboratories, Boston, Massachusetts.

to come nearer to him; or that sounds seem more distant or louder. A present experience may seem to be remembered and thus appear strangely familiar; his environment may seem suddenly strange, or the patient himself seem remote as though he were an onlooker. Such an experience arising from discharge in one or other temporal-lobe cortex suggests that there are in that region localized neuronal connexion patterns that are utilized in the interpretation of visual and auditory experience. This is one form of what was once called an intellectual aura. Hughlings Jackson referred to it as a dreamy state. But included in the dreamy states of Jackson are also the hallucinations which I have for convenience of discussion included with the psychical manifestations of seizures.

Psychical Phenomena

These attacks may end as generalized convulsions and thus may be said to become motor, but in the outset they are purely psychical phenomena.

Hallucinations.—Elaborate hallucinations, like dreams, constitute a moderately common manifestation of a seizure. The localization of ictal hallucinations is in the cortex of one temporal lobe. The experience may be entirely visual, such as a scene from the distant past. There is usually some doubling of consciousness so that the patient recognizes the significance and the unreality of the state. It may be a vivid past experience, such as that of a woman who saw herself giving birth to her child. It may repeat the formula of a familiar childhood dream, but usually it is a simple experience with no psychological significance and the elements are chiefly visual and auditory. Music as a hallucination may be a simple air or it may be a symphony. It seems to arise at the anterior pole of one temporal lobe.

A few examples may be given.

W. D. experienced an epigastric sensation which rose up to his head at the beginning of an attack. Then he heard words, usually those he had heard recently; and yet if he was at the time in conversation or listening to a lecture they were not the words of the speaker. He never thought that someone was talking to him, and he had never been fooled into believing that the radio had been turned on. He might experience the odour of iodoform at such times—suggesting spread of discharge into the uncinate gyrus.

P. R. seemed to hear the music of a symphony for a few seconds, or she would hear voices and might ask her friends to talk more loudly so that she could understand them in spite of these spurious voices. This might be followed by a feeling of warmth in the right ankle and up the right side, which seems to have been a vasomotor phenomenon. Her focus was deep in the left temporal region.

H. P. could remember an aura that referred to her childhood. She seemed to be in a park, and saw a boy there and once a girl. She thought the circumstances were always the same and always familiar. Sometimes the figure or scene came very near her, and then she felt it in her throat. She had a superficial focus in the right temporal lobe. During an operation under local anaesthesia the right hemisphere of the 14-year-old girl was exposed. Some results of electrical stimulation of the temporal cortex were as follows: at one point stimulation caused her to say that she felt as though she might have an attack. When asked what she meant, she said, "That dream, but it passed over." When another point was stimulated she said, "I am seeing somebody." A short interval was allowed and then the point was stimulated again without warning the patient. After a pause she said, "It's coming again." When asked if she saw somebody she said, "Sure, a boy." At another point she said she felt queer; and at still another, lower down, she felt as though an attack were coming on, but it did not come. Stimulation at most of the other points produced some aspect of the dream. At 22 the electrode was kept in place for a longer period. She said, "Dream is starting. There are a lot of people—in the living-room—I think one of them is my mother."

From a psychological point of view there are many interesting aspects to such phenomena. The experience is a continuous progressive one like a dream. It does not happen all at once. In some cases different stages in the dream can be produced by stimulation at different points, and these points remain constant for that particular feature. It is sufficient to point out now that an acquired neuronal connexion pattern, which is evidently related to the mechanism of memory recording, may become so strongly facilitated by the recurring passage over it of an epileptic discharge that it can be activated by electrical

stimulation at various neighbouring points. Furthermore, the patient can himself contemplate such hallucinations and describe them objectively just as he would report a memory that he might summon up.

Forced Thinking.—A feeling of compulsion to think or the occurrence of unusual thoughts may be a preliminary to an attack, although this is quite rare and the descriptions are nearly always meagre, as is shown by the following examples.

H. C. found that his attacks began with an alteration in his thinking. He said he felt himself forced to think about something at these times and that he knew this was a signal that an attack might be imminent. But he could not describe the alterations in his mental processes any further.

W. S. would find himself saying to himself that he "told somebody or other to do this or that." It was usually someone he knew at home, but not always the same person, and he did not seem to see the individual; but he knew a major seizure might be imminent. He stated that a succession of thoughts went through his mind.

J. J. said thoughts crowded into his mind. For example, there was a slice of bread on the table, and he felt it necessary to turn or move the bread. The thoughts did not lead him to do anything, but he knew there was a danger of an attack.

The origin of the attack in these cases has so far proved to be in the posterior part of one frontal lobe anterior to the motor cortex. Perhaps the experience is not properly called forced thinking, for it is remarkable that there are not in our series more complicated types of thought process which the patient can remember. None of the individuals regarded such thoughts as meaning anything—except a warning. Even during this alteration of thinking the subject felt himself to be an onlooker, perceived the significance of the state, and usually tried to turn his mind to something else.

Stereotyped Behaviour.—In a small group of patients there has occurred stereotyped behaviour during a seizure. One man M. R., clutched his own throat as though he would choke himself and resisted with great strength any effort to stop him. He then behaved in a confused manner for hours. He had a scar and an epileptogenic focus, resulting from a depressed fracture, situated in the right frontal lobe near the midline and just anterior to the motor cortex. Electrical stimulation here reproduced the state just described (Penfield and Erickson, 1941). He had amnesia for the whole seizure.

More recently in several similar cases coated electrodes were placed in the subdural and extradural space about the frontal lobes so as to record the beginning and the spread of spontaneous seizures. Without describing these cases in detail here it may be pointed out simply that stereotyped abnormal behaviour has occurred during or just after a localized seizure involving the posterior or median part of one frontal lobe near the longitudinal fissure. It has not yet been observed in association with attacks arising in other areas. How much of the behaviour is the result of release of brain areas by local ictal or post-ictal paralysis and how much is due to discharge in some neurone pattern must remain an open question.

Automatism.—Automatic behaviour as a post-ictal phenomenon has been well described by Hughlings Jackson. This state is a frequent sequel to attacks arising from different areas, but it is seen most often following short attacks localized in the region of one fissure of Sylvius. Most often the seizure manifests itself only as a masticatory attack. Thus the patient smacks his lips and swallows for a time, then he is apt to walk away or move about the house in an aimless manner. Such patients are violent only if opposed. They have amnesia for the period and come to themselves rather suddenly and without a period of sleep. It is obvious that most cortical mechanisms are intact during post-ictal automatism, but the higher neural centres which are the anatomical substratum for conscious activity are paralysed.

Ictal Automatism.—This occurs most frequently in idiopathic or cryptogenic epilepsy. The discharge is evidently taking place in the neural substratum or consciousness just referred to, the highest level of integration. This is evidently a midline area in close anatomical relation with the frontal lobes, to judge from the electro-encephalographic and other evidence that need not be recapitulated now. The attack is commonly referred to as petit mal. The patient may carry on in an automatic manner activity which he had already intended, but he is

onfused. The paralytic effect is produced by the discharge and may be continued during the post-ictal fatigue period. The automatism may therefore be considered both ictal and post-ictal.

Post-Status-Epilepticus Psychotic State.—Finally, psychotic behaviour with negativism, fixed delusions, and hallucinations continuing for days and weeks occurs in rare cases. This is he sequel to a series of seizures continuing for some time. In all patients of this type that we have observed, and in which a focal discharge could be proved, the location of the focus has been in one or other frontal lobe.

For example, N. J. had a small infiltrating tumour in the left posterior frontal area. After admission she had a series of attacks originating in the left frontal region. On the sixth day she was confused, suspicious, negativistic, and said her medicine was poison. Before the attacks Dr. Jasper found multiple spikes, also slow and sharp waves originating from the area of the tumour. But during the negativistic state that followed the seizures there was an increased abnormality of cortical rhythm from the region about this focus, but only minor abnormality from posterior and contralateral regions.

This condition seems to follow a series of seizures. It follows status epilepticus. We have assumed that this is not the result of post-ictal paralysis nor of ictal discharge. Instead, it seems to be associated with an alteration in the normal function of the cortex, chiefly in one area of the brain, and is of interest because of the apparent localization of the abnormality.

Conclusion

In general, automatism may occur during or after a seizure, and post-ictal automatism may succeed ictal automatism with little or no sign of the transition. In either case it seems to be the result of functional paralysis of a restricted area of the central nervous system, an area very high in the scale of functional re-representation. It is a negative manifestation of the attack. On the other hand both hallucinations and perceptual illusions are ictal phenomena and may sometimes be produced by temporal stimulation. These states do not greatly alter the patient's behaviour, for he recognizes them to be spurious. The state which we have called forced thinking is clearly ictal. But it, too, is recognized by the patient as something different from normal thought.

Stereotyped behaviour, like automatism, occurs during a period for which the patient has no memory. It differs from automatism in that there is some definite pattern of action which the patient adopts at such times. Our observations indicate that it is ictal inasmuch as it has occurred during a seizure, but whether the behaviour is the positive result of the discharge, or whether it is due to activity of the central nervous system released from the usual influence of the portion of the frontal lobe that seems to be chiefly involved in the seizure, is not clear.

The Ministry of Education has issued a circular (No. 117) on homecraft as a subject of further education. It is intimated that in framing their plans local authorities should not interpret the word "homecraft" too narrowly, and a list of subjects which it may embrace is given. These include sanitation, ventilation, and water supply, maternity and child welfare, the care of children, and health education, with the treatment of common accidents and ailments. The Ministry says that it should be the aim of education authorities to make provision to cover all these subjects except in so far as the needs are met by other existing agencies such as the maternity and infant welfare service. The educational provision may take various forms such as short full-time courses or longer part-time courses on selected topics, or lectures and demonstrations, or the help given at advice centres by personal contact and simple leaflets. It is added that while this further education in homecraft is primarily directed to women it should not be considered as for women only, and lectures or short courses may well be arranged for fathers and husbands concerning the problem of bringing up children or other home duties.

THE BLOOD GROUP Rh*

BY

D. F. CAPPELL, M.D., F.R.S.Ed.

(From the Department of Pathology of the University and Western Infirmary, Glasgow)

PART II

CLINICAL APPLICATIONS IN TRANSFUSION THERAPY AND IN HAEMOLYTIC DISEASE OF THE NEWBORN

The Rh Factor in Blood Transfusion Therapy

As shown in the foregoing section, in each individual the Rh factor consists of two sets of three elementary antigens, and theoretically the recipient of a blood transfusion might develop antibodies against any one of the antigens which he or she lacks. Thus far five of the six possible antibodies have been identified, but while some are common others are exceedingly rare. ABO blood grouping is now so well understood and reliable grouping sera are so generally available that transfusion reactions due to errors in ABO groupings are rare. Reactions between bloods compatible on the basis of ABO groups are designated "intra-group reactions," and such intra-group incompatibility is due mainly to the Rh factor, although on rare occasions other blood group factors such as P, M, and N may be concerned.

When a Rh-negative individual receives repeated transfusions of Rh-positive blood the first transfusion is normally symptomless, and the transfused cells may survive satisfactorily in the recipient's circulation. In others the donor's cells are destroyed more quickly than usual, and the lasting benefit may not be obtained. Further transfusions of Rh-positive blood in such cases are likely to be followed by progressively more severe symptoms—chills, headache, rigors, jaundice, and, later, haemoglobinuria and anuria. These phenomena are due to iso-immunization of the Rh-negative recipient by the antigens of Rh-positive blood, and are commonly accompanied by the appearance of Rh antibodies in the serum. In most cases transfusion of Rh-positive blood must be repeated several times before iso-immunization appears; but, exceptionally, a single transfusion may initiate the process and a second transfusion be treated as incompatible (Callender and Paykoç, 1946). These workers made a careful follow-up of 100 cases. In all groups there were only two with irregular iso-agglutinins, active at 37° C., but several of the 15 Rh-negative recipients had failed to become immunized or sensitized in spite of having received as many as 30 transfusions over a period of two years. Lack of reaction in the first transfusion of Rh-positive blood to a Rh-negative recipient does not always apply to women in pregnancy or, indeed, to women who have previously borne children; this aspect of the subject is considered in detail later.

When iso-immunization of a Rh-negative recipient cde/cde is induced by transfusion of Rh-positive blood it is usually the elementary antigen D which is effective. The transfused blood in 70% of cases will contain the antigens CDe (type Rh, 70%) and in 30% the antigens cDE (type Rh, 30%), although in about one-half of the latter the R₂ will be associated with R₁ (type Rh,R₂=15%). The resulting antibodies have usually the specificity of anti-D (85%), but this may be accompanied by the agglutninoid or blocking anti-D, so that agglutination is not apparent in tests conducted by the standard saline dilution method. In some cases the anti-D is accompanied by anti-C, and a double agglutinin serum (anti-Rh₁=87%) results. If in this case sufficient blocking anti-D develops to neutralize the agglutinating anti-D the resulting serum gives the reactions of anti-C (70%). When the transfused cells have been of type Rh, (cDE) only the D is usually effective and the elementary antigen E rarely gives rise to antibodies; when it does, a double agglutinin serum results (anti-D plus anti-E), and here, too, the development of blocking anti-D can give rise to a serum of more restricted specificity—the 30% anti-Rb" (i.e., anti-E type).

An important aspect of this question is the observation that once sensitization has been established it appears to remain

* A B.N.A. lecture delivered before the Ayrshire Division on Feb. 24, 1946.

permanently imprinted on the recipient's constitution, and a further transfusion, even many years later, may be followed by a severe reaction (anamnesic reaction). There are therefore good grounds for the view (Cappell, 1944) that females in or below the reproductive period should receive by transfusion only blood of similar Rh type to their own. Diamond (1945) has emphasized that sensitization of the Rh-negative woman by transfusion of Rh-positive blood leads to the most severe forms of haemolytic disease in subsequent pregnancies, and evidence is accumulating that the indiscriminate use of blood transfusion in women without regard to the Rh factor is dangerous, and carries an unjustified hazard for the future (see leading article, *B.M.J.*, 1945, 2, 535). In my opinion no woman in the reproductive period should ever be given blood until it has been ascertained whether she is Rh-positive or Rh-negative, and she should then receive only the appropriate type. This ideal state may be difficult to realize at present, but it represents what should be aimed at, and it would be possible if the clinicians demand it and give the necessary co-operation. In obstetric emergencies the Rh grouping is essential and should never be omitted (see later); in operations of election and in medical cases the question should be anticipated and the Rh type ascertained beforehand along with the ABO group. Every pathological or haematological department worthy of the name should be prepared to carry out such tests as required, and be able to provide the answer within a few hours at most.

Rh Factor in Pregnancy

Since approximately one marriage in eight involves a Rh-positive man and a Rh-negative woman, in about one pregnancy in ten the foetus is Rh-positive and the mother Rh-negative. Sensitization appears to occur only in about one in 25 opportunities—i.e., haemolytic disease may be expected in about 1 in 250 births. Rh incompatibility is therefore by far the most important genetic cause of foetal death, and it far outweighs congenital syphilis, with which it used to be so often confused, as a factor in neonatal mortality; nevertheless much more time and effort are put into the search for maternal and congenital syphilis in the antenatal clinics and their attendant laboratories than into Rh investigations. As in transfusion risks, the danger arises from immunization of Rh-negative mothers, in this case by a Rh-positive foetus who inherits the Rh-positive gene from the father. Taylor and Race (1944) point out that iso-immunization is more likely to occur where the father is homozygous Rh-positive (RhRh), so that each successive foetus carries the Rh-positive gene, but the disease is by no means rare with heterozygous fathers (Rhrh). In my own series many of the fathers have not been genotyped, either because they were not available or because at that time the investigation was not advanced enough and further samples could not be obtained later. I have, however, records of the father's genotype in 38 cases, and of these 22 are homozygous and 16 are heterozygous Rh-positive.

Illustrative Cases

Case 1.—Mrs. G.: Group A Rh-negative, rr, cde/ede. Mr. G.: Group O Rh-positive, Rh,Rh, CDe/CDe. 1939: Female; alive and well; Group O, R,r, CDe/ede. 1940: Female; alive and well; Group O, R,r, CDe/ede. 1941: 8/12 twins; died two days, icterus gravis neonatorum. 1942: Male; died two days, icterus gravis neonatorum. 1943: Male; died two days, icterus gravis neonatorum. 1945: Male; macerated foetus; Group O R,r, CDe/ede. The serum contained anti-Rh₀ (anti-D) titre 1:8.

This family illustrates the typical course of iso-immunization in a Rh-negative woman with a homozygous positive husband. Haemolytic disease has recurred in each child after the first appearance of the disease, and it is extremely unlikely that any normal child will be born.

Case 2.—Mrs. C.: Group O Rh-negative, rr, cde/ede. Mr. C.: Group B Rh-positive, R,R, CDe/CDe. 1931: Miscarriage 2½ months. 1932: F.; Full-time stillbirth. 1934: Miscarriage 2½ months. 1936: F.; f.-t. S.B. 1938: M.; f.-t.; lived two days jaundiced. 1945: F.; Group B Rh-positive, R,r, CDe/ede.

The infant born by Caesarean section showed extreme anaemia and mild hydrops. A slow transfusion of 180 ml. of Rh-negative blood was begun within 15 minutes of birth, and the infant was apparently well for about 36 hours in spite of fairly severe jaundice. It then became dyspnoeic and died

suddenly. Necropsy showed severe erythroblastosis and pronounced kernicterus involving all the nuclei of midbrain and medulla, the olivary nuclei being most deeply stained.

Case 3.—Mrs. S.: Group O Rh-negative, rr, cde/ede. Mr. S. Group O Rh-positive, heterozygous R,r, CDe/cde. 1st: F.; f.-t. a. and w. 2nd: M.; induced two weeks before term; a. and w. Group O Rh-negative, cde/cde. 3rd: F.; foetus malformed I.G.N.; died third day. 4th: F.; induced two weeks before term a. and w.; Group O Rh-negative, cde/cde. 5th: F.; S.E. hydramnios; jaundiced. 6th: Hydramnios; premature S.B.

This patient's serum contains a weak agglutinating antibody of type anti-Rh₀ (anti-D). It is noteworthy that both of the children surviving after the firstborn are Rh-negative and presumably have escaped haemolytic disease in consequence of their lack of Rh antigen.

Case 4.—Mrs. Ma.: Group A, Rh-negative, rr, cde/cde. Mr. Ma.: Group O Rh-positive, R,, presumably R₂R₂, CDe/CDe. 1st: a. and w.; A, R₂r, cDe/cde. 2nd: a. and w.; A, R₂r, cDe/cde. 3rd: a. and w.; not tested. 4th: F.; a. and w.; A, R₂r, cDe/cde. 5th: F.; f.-t.; congenital anaemia; Group O R,r, cDe/cde.

The mother's serum contained a powerful anti-Rh₀ agglutinin, titre 1:512; this was also present in the breast milk (titre 1:64). The baby appeared normal at birth (Hb 116) and there was no erythroblastemia. On the fifth day the infant was slightly jaundiced and was losing weight; its haemoglobin had fallen to 78%. Breast feeding was stopped. The haemoglobin continued to fall, and after four weeks the mother brought the child back to the clinic on account of pallor. Haemoglobin level was then only 26%. A slow transfusion of 180 ml. of Group O Rh-negative blood was given as packed cells resuspended in 90 ml. of saline, and thereafter the child made a good recovery. The ingestion of anti-Rh in the breast milk may have aggravated the condition, and gain in weight began only after the breast feeding was stopped.

Case 5.—Mrs. A.M.: Group A Rh-negative, rr, cde/cde. 1st: A.M.: Group O Rh-positive, probably Rh,Rh, CDe/CDe. 1st: 3/12 miscarriage. 2nd–10th: All a. and w.; all A, R,r, cDe/cde. 11th: 3/12 miscarriage. 12th: F.; a. and w.; A, R,r, cDe/cde. 13th: 3/12 miscarriage. 14th: F.; premature; I.G.N.; Group R,r, cDe/cde.

In this remarkable family after an initial miscarriage 1 Rh-negative mother bore 9 successive normal Rh-positive children, and only at the 14th pregnancy was haemolytic disease recognized. Since all the children are type R,r it is highly probable that the father is homozygous R₂R₂. The baby was seen only on the fifth day, when jaundice was already pronounced, but after a transfusion of 100 ml. of Rh-negative blood gradual improvement took place and subsequent progress was satisfactory.

Case 6.—Mrs. H.: Group A, Rh-negative, R'r, Cde/cde. Mr. H. Group A, R,r, CDe/cde. 1st: M.; f.-t.; a. and w.; A, R,r, CDe/cde. 2nd: M.; f.-t.; d., I.G.N.; presumably R₂r or R₂R'. 3rd: M.; f.-t.; d., I.G.N.; presumably R₂r or R₂R'. 4th: M.; f.-t.; a. and w.; A, R'r, Cde/cde. 5th: M.; f.-t.; a. and w.; A, R,r, cde/cde. 6th: M.; f.-t.; a. and w.; A, R,r, cde/cde. Maternal serum contained a weak anti-Rh₀ agglutinin.

This family illustrates well the segregation of Rh genes. The mother lacks component D, and became iso-immunized by D antigen of the first child, so that the second and third child died of icterus gravis, while the fourth and fifth children lacked antigen D, escaped the disease. This case illustrates the danger of including R' in the Rh-positive class. If the patient were transfused with Rh-positive blood type R₁ or R₂ she would experience severe and possibly fatal haemolytic reaction.

Cases of this kind have been reported by Wiener (1945b) and by Simmons and Kelsall (1945) as examples of iso-immunization of Rh-positive mothers. In my view they ought to be classified as Rh-negative.

Case 7.—Mrs. G.: Group A, Rh-negative, rr, cde/cde. Mr. G.: Group A, Rh-positive, R,r, cDe/cde. 1st: F.; a. and w.; A, R,r, cDe/cde. 2nd: M.; a. and w.; A, R,r, cDe/cde. 3rd: F.; a. and w.; O rr, cde/cde. 4th: F.; f.-t. S.B. 5th: M.; premature S.B. 6th: F.; premature (5½ months) S.B.; hydrops foetalis; probably R,r.

The sixth pregnancy terminated with a severe concealed accidental haemorrhage, for which the patient was admitted to hospital as an emergency. No urine was obtained on

theterization. A blood transfusion (Group A Rh-positive) as followed by a severe rigor and delivery of a stillborn hydropic foetus weighing 2 lb. 12 oz. (1.35 kg.). The placenta weighed 2 lb. 2 oz. (0.96 kg.). Anuria persisted and death occurred five days later. Necropsy revealed bilateral cortical necrosis of the kidneys and extensive anterior pituitary necrosis.

The mother's pre-transfusion serum was later found to contain anti-Rh, agglutinins; these diminished greatly after transfusion, but the titre had risen again before death. The baby's cells appeared to be Rh-negative, but it is almost certain that they were really R_r (cDe/cde) with the D antigen rendered unrecognizable by the action of blocking anti-D substance.

The father and two of the children are of this rare type, so that in the absence of the components C and E the blocking of D rendered the cells serologically Rh-negative.

Case 8.—Mrs. Fl.: Group O Rh-negative, rr, cde/cde. Mr. Fl.: Group O Rh-positive, R_rR_r, CDe/CDe. Baby Fl.: Group O, apparently R_r; I.G.N. (?Cdc/cde.)

The child suffered from haemolytic disease type II, but its cells were not agglutinated by the mother's serum or by any anti-Rh, (anti-D) serum; agglutination was obtained with anti-Rh' sera (anti-C), and the cells accordingly appeared to belong to type Rh—a finding which not only failed to explain the haemolytic disease but also conflicted with the rules of inheritance. The child was transfused with Rh-negative blood and made a good recovery from haemolytic disease; when tested three months later the cells were found to be of type R_r CDe/cde, as had been suspected.

The mother's serum failed to agglutinate saline suspensions of known Rh-positive cells by the normal titration method, but caused agglutination when mixed with undiluted Rh-positive blood. Known Rh-positive cells after treatment with saline dilutions of maternal serum were found to be insusceptible to the action of known anti-D sera; it is therefore certain that Mrs. Fl.'s serum contained a pure blocking anti-D antibody which, by saturating the receptors of the child's red cells, had rendered them temporarily Rh-negative. This is probably the explanation of the finding of Rh-negative (R') cells in cases 59 and 78 in the series of Plaut, Barrow, and Abbott (1945).

Case 9.—Mrs. Sm.: 23; Group O Rh-negative, rr, cde/cde. Mr. Sm.: Group O Rh-positive, R_rR_r, CDe/CDe. 1st: a. and w. 2nd: I.G.N.; recovered, but suffered from kernicterus and is backward. 3rd: Group O R_r, born by Caesarean section; transfused immediately through umbilical vein, 150 ml. Rh-negative blood; became severely jaundiced, but recovered; Hb fell to 55% at 5 weeks of age; a second transfusion given with great improvement. Infant fed on heated breast milk obtained by expression.

The mother's serum contained an anti-Rh titre. 1:16. This child was almost certainly saved by immediate transfusion.

Case 10.—Mrs. B.: Group O Rh-negative, rr, cde/cde. Mr. B.: Group A Rh-positive, R_r, probably CDe/CDe. 1931: F.; f.-t.; a. and w.; Group O R_r, cDe/cde. 1932: F.; f.-t.; a. and w.; Group O R_r, cDe/cde. 1934: F.; f.-t. S.B. 1935: F.; f.-t. S.B. 1936: M.; f.-t. S.B., jaundiced. 1937: F.; f.-t.; born jaundiced but recovered; A R_r, cDe/cde. 1938: M.; f.-t.; a. and w.; O R_r, cDe/cde. 1941: 6/12 miscarriage. 1945: F.; hydramnios; accidental haemorrhage; macerated hydropic foetus.

This case presents several remarkable features. The history strongly suggests that the stillbirths of the third, fourth, and fifth children were due to haemolytic disease; the sixth child, although jaundiced, recovered, but the seventh child did not appear to be affected; the sixth and seventh children are Rh-positive. Three years later the eighth pregnancy miscarried, and four years thereafter the ninth pregnancy ended in the birth of a macerated hydropic foetus, following severe accidental haemorrhage, for which transfusion of plasma was given.

When the maternal serum was tested six days after delivery a powerful anti-Rh, (anti-D) was found, which gave agglutination in saline dilutions up to 1:1,600. Four days later a pint (568 ml.) of blood was removed for use as a reagent; but, surprisingly, this sample, while failing completely to produce agglutination in full strength, gave a marked prozone effect, agglutination appearing at 1:128, increasing to 1:512, diminishing at 1:800, and vanishing at 1:1,200.

Case 11.—Mrs. He.: Group A Rh-negative, cde/cde. 1935: F.; f.-t.; a. and w. 1937: F.; f.-t.; a. and w. 1941: F.; f.-t.;

a. and w. 1945: Termination of pregnancy by abdominal hysterectomy on account of *severe toxæmia*. The foetus was thought to be hydropic and the placenta was unduly large. Subsequently the blood was examined and found to be Rh-negative, with a moderately good anti-Rh, titre, 1:16. Had this patient been given a transfusion of Rh-positive blood the effects might have been disastrous.

Case 12.—Mrs. McR., aged 39: Group A Rh-positive, Rh,rh. Mr. McR.: Group A Rh-positive, Rh,Rh, 1936: f.-t.; unexplained S.B. 1938: f.-t.; jaundiced at birth, lived 24 hours. 1942: f.-t.; a. and w. 1944: f.-t.; jaundiced at birth, lived 24 hours. 1946: f.-t.; a. and w. Group A Rh,rh. The patient's serum was tested at intervals during her last pregnancy, and a trace of anti-E agglutinin was detected, but the titre did not alter. In view of the history of two neonatal deaths, and also because she lived in the Outer Hebrides, the patient was transferred to Glasgow by air for confinement in the Glasgow Royal Maternity Hospital. Arrangements were made to transfuse the infant, if its genotype included Rh, (i.e., Rh,Rh, or Rh,rh), with blood of type Rh, or Rh-negative (rh,rh), but examination of the cord blood sample immediately after birth showed the genotype to be Rh,rh and therefore likely to be unaffected; there was no erythroblastæmia, and the infant remained well without treatment.

The Pathogenesis of Haemolytic Disease

If we take into account both agglutinating and blocking antibodies the majority of the mothers of infants suffering from haemolytic disease are found to show evidence of iso-immunization. All recent investigations have confirmed that iso-immunization of the mother is the fundamental cause of haemolytic disease. In some cases agglutinating antibodies are found, in others agglutinoids or blocking antibodies; and in a proportion in which neither of these can be demonstrated the infant's red cells are observed to be sensitized when the Coombs test with rabbit anti-human-globulin serum is applied (Coombs, Mourant, and Race, 1946).

In our series of 114 cases of haemolytic disease 98 of the mothers have been found Rh-negative, and 86 of these had antibodies. Among 16 Rh-positive cases only two had antibodies recognizable by the ordinary saline-dilution method, but most of these were encountered before the recent more sensitive methods, such as Diamond's slide test or Wiener's "conglutination" test, were known. It is probable that the more sensitive methods would have raised the number with recognizable antibodies still higher.

It is reasonable to suppose that the passage of these harmful substances through the placenta and consequent damage to the haemopoietic system of the foetus constitute the fundamental pathology and that, as Parsons, Hawksley, and Gittins (1933) first maintained, it is essentially a haemolytic disease. The iso-antibodies so far revealed are mainly concerned with agglutination, and haemolysins acting in association with complement *in vitro* have not been demonstrated. There is reason to suppose that the "blocking" antibodies are even more harmful than the Rh agglutinins first observed; they generally appear in the later-affected pregnancies, and their appearance is often followed by the birth of a macerated hydropic foetus. Diamond and Denton (1945) refer to them as the "mature" type of antibody and to the simple agglutinins as the "immature" type. Much is still obscure about the mode of action of blocking antibodies *in vivo* and the production of such dramatic results immediately after birth. The absence of jaundice at birth in most of the affected infants may be explained by the excretion of the excess of foetal bilirubin through the placenta, and it may be that other harmful substances produced by the interaction of foetal antigens and maternal antibodies are also excreted by this route so long as the foetus is *in utero*. With the establishment of independent existence at birth, such "toxic substances" might perhaps accumulate and attain a concentration sufficient to damage the foetal tissues. Certainly many infants show severe liver damage and the occurrence of cerebral necrosis with kernicterus is well recognized.

Time of Occurrence of Haemolytic Disease in Affected Families

Haemolytic disease rarely appears in the first pregnancy; in some the second conception is affected, but in others several healthy children are born before the disease declares itself, as has been illustrated in the cases presented. In our 98 affected families with Rh-negative mothers the average parity of the

mothers when the disease first appeared was 3.2 in families with hydrops foetalis, 3.6 in families with icterus gravis, and 4.8 in families with congenital anaemia. Average figures, however, give only an imperfect view of the facts, for the range of variability is remarkable. Thus in only four families was haemolytic disease proved in the first pregnancy, and one of these was a dizygotic twin pregnancy. On the other hand, we have numerous records of families, such as No. 5 (above), in which haemolytic disease appeared only after ten or more pregnancies; and I have previously (Cappell, 1944) recorded data showing 37 Rh-negative multiparae who had lost not a single child; these included two mothers with Rh-positive husbands and 13 and 14 living children respectively.

It is difficult to say at which conception haemolytic disease first occurred, for in many families one or more miscarriages are recorded before the existence of haemolytic disease is proved. Where a succession of miscarriages culminates in icterus gravis or hydrops foetalis the earlier disasters may also have been due to the same process. In other cases one or more normal Rh-positive children are born between the early miscarriages and the frank haemolytic disease, which then seems a less probable cause for the miscarriages. I have not personally encountered a single case where a normal healthy Rh-positive child has been born to a Rh-negative mother after haemolytic disease has been proved in her earlier offspring; but families such as No. 10 in the above series are very striking, and it is difficult to avoid the conclusion that the third, fourth, and fifth foetuses suffered from fatal haemolytic disease. The sixth was affected but recovered, and while the seventh appeared to escape harm, it may have suffered from anaemia which was not detected.

However suggestive these histories may be, it is well to point out that the cause of death in the earlier infants was not fully ascertained, as post-mortem examinations were not made. Dr. Stanbury (Leeds) and Dr. Chown of Winnipeg have both encountered cases where a healthy unaffected Rh-positive child was born to a Rh-negative mother who had previously borne a child with severe haemolytic disease, but the ABO groups of mother and family are not available to enable an assessment of the influence of homo- or heterospecific pregnancy.

We do not yet know why some Rh-negative mothers react so quickly to the Rh antigen of the foetus while others appear to ignore it, but clearly there are important factors concerned other than the mere Rh difference between the father and mother. The observation that the transfusion of Rh-positive blood into Rh-negative recipients may also fail to excite any immunological response indicates that individuals vary greatly in their capacity to respond to the Rh antigens. There is some evidence that this aptitude to become immunized may also be an inherited character (Race).

Influence of Heterospecific Pregnancy

We have long suspected that iso-immunization in pregnancy against the Rh factor occurs more often when the ABO group of the foetus is compatible with the mother's blood than when it is incompatible. Such an incompatibility is designated "heterospecific pregnancy," and may be expected to occur in normal families in about 20 of every 100 random matings. To ascertain the influence of heterospecific pregnancy we require the ABO groups of mother and child, but where the child's group is unknown, as is likely to occur in stillbirths and miscarriages, the father's group may be helpful. When the father belongs to Group O he cannot transmit an ABO antigen which the mother lacks, and also, if his ABO group is the same as the mother's the pregnancy is bound to be homospecific. From our first series of 50 well-authenticated cases of haemolytic disease it appeared that the Rh-positive child of a Rh-negative mother was more likely to be affected with haemolytic disease where the father's ABO group was compatible with the mother's than where it was incompatible; but satisfactory analysis was impossible owing to the gaps in our information due to the absence of so many of the fathers on service. The recent figures of Plaut, Barrow, and Abbott (1945) show a significant deficiency of Group O mothers and an excess of Group A mothers, whereas among the husbands there is an excess of Group O and a deficiency of Group A. Further analysis of their table shows that, among 103 families for which sufficient

data are given, 92 pregnancies were homospecific and only 1 heterospecific, and of these no fewer than 7 were in Rh-positive mothers.

The figures for our own cases in proved Rh-negative mother 90 in all, in which the groups of mothers and children at known or in which a heterospecific pregnancy is known to be ruled out by the father's group, show a striking deficiency of heterospecific pregnancies among the Rh-negative mothers—viz., only 8 heterospecific to 82 homospecific, whereas the expected random distribution among 90 pregnancies would be approximately 18 and 72 respectively.

The meaning of this difference in susceptibility is not at all clear. Wiener (1945c) has also observed the difference in incidence, and suggests that it may be due to what he terms the "competition of antigens." In a heterospecific pregnancy, the Rh-negative maternal tissues are subjected to the influence of A or B substances as well as Rh. Wiener suggests that A and B are better antigens and that the development of anti-A or anti-B takes precedence over the development of anti-Rh. Smith (1945) has shown that in heterospecific pregnancy the maternal iso-agglutinin corresponding to the incompatible group of the infant rose in 40 out of 46 cases, and that in the six cases in which a rise failed to occur the infant was found to be a non-secretor. This suggests that the rise in maternal iso-agglutinins may be due to the diffusion of soluble A or B substance from the foetus into the maternal circulation, and that escape of foetal red cells is not usually concerned. The relative absence of soluble Rh substance in the plasma has, however, led to the general acceptance of the view that escape of foetal red cells into the maternal blood is the probable mechanism of iso-immunization against Rh. Diamond (1944) has shown that rapid and powerful regeneration of anti-Rh substances may be induced in previously iso-immunized volunteers whose agglutinin titres had fallen by repeated intravenous injection of minute doses (0.01–0.05 ml.) of human red cells of the appropriate type, and this has been confirmed by Callender and Race (1946) and by Stanbury (1946). It is clear, therefore, that repeated minute doses may be effective, and pregnancy offers conditions in which the antigen may have prolonged access to the recipient. Stratton (1943) has shown that Rh antigens are present in the red cells of a 48-mm human embryo, and Dr. McFarlane and I have confirmed this in the cells of several foetuses of 10 to 12 weeks' gestation who were strongly Rh-positive. The Rh factor is therefore well developed at a period of gestation when the A and B agglutinogens are yet imperfectly formed. Clearly, however, heterospecific pregnancy in a Rh-negative mother does not give absolute protection against the development of Rh antibodies—e.g., family above. We have shown that when the mother is of Group Rh-negative and the husband of Group A or B Rh-positive haemolytic disease is encountered less often than is to be expected on the frequency of these matings. In affected families, however, when the husband is heterozygous for A or B i.e., genotype AO or BO—it is not apparent from published work that the incidence of haemolytic disease is any greater among the O children than among the A or B children. Few of the family studies, however, give enough details to enable a proper estimate of the situation to be made.

Management of a Case of Haemolytic Disease

It is convenient to consider this problem under two heads: (a) when a child is affected in a family already known to be afflicted with haemolytic disease, and (b) when a child born alive develops icterus gravis or congenital anaemia without previous warning of this possibility.

(a) Procedure when Haemolytic Disease is Anticipated

When a child has been shown to suffer from one of the forms of haemolytic disease—e.g., hydrops foetalis, icterus gravis, or congenital anaemia—in addition to such steps as may be necessary to save the child, if alive, information should be collected in anticipation of a repetition of the disease in future pregnancies. Much of this information will be gathered if treatment of the affected child is undertaken, but where the child is stillborn or dies, it is still important to prepare for the future by examining the blood of the mother and father for

their ABO group and Rh factor, and for the presence of anti-Rh in the mother's serum. Assuming that the mother is Rh-negative and the father Rh-positive, as is likely in a true case of haemolytic disease, the genotype of the father should be determined if possible. If he belongs to phenotype Rh, (70%) it can be shown whether he is homozygous (Rh,Rh, or Rh,Rh₂) or heterozygous (Rh,rh); if, however, he belongs to phenotype Rh₂, (15%) the distinction between the homozygous Rh,Rh, and the heterozygous Rh,rh can be made only by Mourant's serum (anti-e), with which the homozygotes are negative. Supplies of this serum are unfortunately not generally available. If the father is homozygous all subsequent children are likely to be affected; if heterozygous, each pregnancy has a 50% chance of resulting in a Rh-negative foetus which will not suffer from haemolytic disease.

When the mother again becomes pregnant her serum should be examined at monthly intervals from the sixth month onwards; if anti-Rh agglutinins are present a rising titre suggests that the foetus is Rh-positive and will be affected, but failure of the titre to rise does not mean that the foetus is unaffected, and in some the anti-Rh agglutinins disappear owing to the development of the blocking form of the antibody. This is usually a serious prognostic sign, and is often followed by the birth of a hydropic infant or macerated foetus. A sample of maternal serum is preserved in readiness to perform cross-matching tests in case the mother herself should require a transfusion, for the consequences of giving an incompatible blood are likely to be very serious. Arrangements should be made to have readily available Rh-negative blood of the appropriate group or of Group O, and to give the child a transfusion within the first few hours if it should prove to be affected.

If the foetus suffers from the most severe form of haemolytic disease—viz., hydrops—the pregnancy will probably terminate prematurely in the birth of a macerated hydropic foetus, and the large size and unhealthy appearance of the placenta will probably attract attention. With icterus gravis, however, the outlook is more favourable, and the pregnancy usually goes to about full time.

In some families there is a history of repeated intrauterine deaths between the 37th and 40th weeks, and it is therefore tempting to induce labour a few weeks before term in the hope of securing a living child. We have observed, however, that affected infants are unduly prone to intranatal death from asphyxia, and it is therefore essential that induction should not be followed by a prolonged labour. Where the mother is desperately anxious to secure a living child Caesarean section about the 37th week and immediate transfusion of the affected infant probably offer the best chance.

It is rarely possible to say from the external appearance of the infant at birth whether it is normal or affected, but in the latter we have observed that the umbilical cord may look abnormally yellow; jaundice is only occasionally present at birth, as during foetal life the excess bilirubin derived from haemolysis is excreted through the placenta and is removed by the maternal circulation. Discoloration of skin and mucosae usually appears within a few hours; petechial haemorrhages in the skin also develop, and sometimes haemorrhagic manifestations dominate the clinical picture. It is of the utmost importance not to wait until clinical signs of the disease appear, but to try to establish the diagnosis immediately and institute treatment without delay. As soon as the umbilical cord is cut a sample of blood is collected from the maternal end into a sterile bottle containing anticoagulant, preferably heparin. When centrifuged immediately, the supernatant plasma is, in affected infants, usually jaundiced to a pronounced degree, and this is a valuable sign which can easily and quickly be detected without waiting for clinical evidence of jaundice. Care must be taken to prevent admixture of the cord blood with Wharton's jelly, as this interferes with agglutination; contamination with maternal blood must of course be avoided. When there is a clear history of haemolytic disease in a previous child it is probably wisest to establish at once whether the child under consideration is Rh-positive, and if so, on the assumption that it will be affected, a transfusion should be given immediately, without delaying until the results of the full blood examination are known. These can be carried out at leisure on its heparinized cord blood.

(b) Procedure when a Child Develops Icterus Gravis without Previous Warning

Haemolytic disease should be suspected when jaundice appears within a few hours of birth, though it may be delayed up to 48 hours. Physiological jaundice, on the contrary, rarely appears earlier than 48 hours, but no absolute time limits can be laid down. Rapidly deepening jaundice accompanied by drowsiness and failure to feed satisfactorily is highly suspicious, and if the child is at home it should be sent into hospital as an emergency case for diagnosis and treatment. Along with the child 10 ml. of the mother's blood must be sent to the hospital to establish whether she is Rh-negative and what kind of anti-Rh is present, as this determines what sort of blood should be transfused into the child. If cord blood is not available a sample of the child's blood should be taken from a heel puncture; the haemoglobin estimation, red and white cell counts are performed; and films are made. A few drops of the blood are also used to make a suspension in 3 ml. of glucose-citrate saline for grouping and Rb tests.

In the laboratory the bloods of mother and child are grouped and Rh tests are started at once. The mother's serum is also put up against a panel of known Rh-positive and Rh-negative Group O cells, and against the infant's blood if the ABO groups permit. If not, the α and β of the maternal serum are neutralized by the addition of one part of boiled saliva from an A,B secretor to two parts of maternal serum, and after fifteen minutes the mixture is set up with the infant's cells. Tested saliva should be kept on hand in the laboratory for this purpose.

In haemolytic disease the haemoglobin is usually, but not invariably, below the normal birth level, the red cells are reduced, but reticulocytes are abundant. The nucleated cell count is often over 20,000, but nucleated red cells may comprise the majority and are of all kinds; normoblasts, megaloblasts, and primitive cells are all present. We regard the occurrence of primitive cells as especially significant, and while a nucleated red cell count of over 6,000 is usually an indication of haemolytic disease, lower figures or even an absence of erythroblastæmia do not rule out this diagnosis. By the time the counts have been done and the films examined the Rh tests can usually be read. If there is a history of proved haemolytic disease in a previous child the finding that the infant under consideration is Rh-positive from a Rh-negative mother is a definite indication for immediate transfusion, since it is highly improbable that a subsequent Rh-positive child will remain unaffected. If, on the other hand, the child under consideration is the first to be suspected, we require additional proof, clinical or haematological, of haemolytic disease before instituting treatment. This is important; for the development of routine antenatal Rh-testing will reveal many Rh-negative mothers whose infants will prove to be normal. Confirmatory evidence is found in the occurrence of erythroblastæmia, of rapidly deepening and severe jaundice, or of pronounced anaemia, but the absence of any of these signs does not controvert the diagnosis. Caution is necessary, for so-called physiological icterus may occur in the Rh-positive children of Rh-negative mothers and, as usual, is without grave significance; it does not require treatment by transfusion.

Treatment of Haemolytic Disease of the Newborn

With better understanding of the aetiology of haemolytic disease the rational treatment is clearly the transfusion of blood which is not susceptible to the action of the maternal iso-antibodies, and in most institutions this has improved the prognosis greatly. Accordingly, in about 90% of cases Rh-negative blood of a homologous group or of Group O is required, and should be given in amounts up to 150 ml. More than this quantity in a single transfusion is inadvisable, and the blood should be administered slowly, preferably as a drip by a gravity method rather than by a two-way syringe, as this commonly leads to too rapid administration. The dangers of rapid transfusion and consequent circulatory overloading are not sufficiently realized; the normal blood volume of a 7-lb. (3.175 kg.) baby is about 250 ml., and 150 ml. to a newborn infant is roughly equivalent to three litres to an adult; yet it is not uncommon to find that paediatricians administer 150 ml. or more in 15 to 20 minutes by a two-way syringe method. The infant with haemolytic disease generally shows considerable

hypertrophy of the heart, and it is hardly surprising that acute cardiac failure from circulatory overloading sometimes leads to death at the end of a transfusion by this method. It is preferable, therefore, to give only a moderate quantity of blood, and to repeat the transfusion later if necessary.

Experience has led me to believe firmly in early transfusion; it is a mistake to await the onset of symptoms, and transfusion should be administered at the earliest possible moment, giving 120 to 150 ml. of Rh-negative blood of the child's group or of Group O. The absence of marked anaemia is not an indication for withholding transfusion, for a high haemoglobin and red cell count may be an expression of excessively active haemopoiesis from abundant extramedullary centres. If the clinician is afraid of plethora from the administration of 150 ml. of blood to an infant whose haemoglobin level is 120%, it is worth removing blood from the infant before transfusing with Rh-negative blood. For this reason where the disease is anticipated no attempt should be made to secure the return of blood from the placenta to the baby, but the cord is clamped as soon as possible to prevent the reflux of placental blood. The rationale of administering a relatively large transfusion to the non-anaemic infant is that the Rh-negative blood persists unaffected by the irregular antibodies, and thereby helps to inhibit rapid regeneration of the infant's own Rh-positive and therefore susceptible cells. By thus suppressing haemopoiesis the severity of the jaundice is diminished and the risk of severe liver damage and of kernicterus seems to be lessened. When transfusion has been carried out within the first 24 hours the jaundice may fail to deepen and may disappear more rapidly than in infants transfused only later.

We prefer the intravenous route, using the internal malleolar vein, but do not cut across or tie off the vein; a limited experience of intramedullary transfusion of blood has not been very encouraging. The infant's Hb level is watched daily, and sometimes a second transfusion is necessary after a few days, for by this time a large part of the child's own Rh-positive blood may have been destroyed, so that life is maintained on the Rh-negative transfused cells. Two transfusions have usually sufficed, but in infants not transfused until the fourth or fifth day more may be required. It cannot be too strongly emphasized that speed in diagnosis and treatment is essential if the best results are to be obtained, and that the longer transfusion is delayed the greater the chance that it will have to be repeated. No other treatment is usually necessary. Where laboratory facilities for carrying out the tests are properly organized the tests can be completed and the transfusion begun within an hour.

In a family previously affected but with a heterozygous father, examination of the infant's blood may show it to be Rh-negative (rr, cde/cde). In this event treatment is unnecessary, since there is no reason to suppose that a Rh-negative child will be affected. Our experience here has been perfectly clear. In a study of 650 antenatal cases Dr. McFarlane observed 90 Rh-negative mothers, 31 of whom gave birth to normal Rh-negative children, including two Rh-negative normal children in families whose previous Rh-positive children had been affected. She also examined, soon after birth, the blood of 52 Rh-positive children from the same group of Rh-negative mothers without a previous history of haemolytic disease: 48 of these were normal and no treatment was given, but 4 were found to suffer from haemolytic disease and were immediately treated. All survived and have remained well.

It must be remembered that occasionally an affected child will appear to be Rh-negative owing to the saturation of the D receptors of its erythrocytes by "blocking" antibody. Tests with anti-C and anti-E serum will make the child seem to belong to the R' or R'' subgroup, but in such cases the Coombs test with rabbit anti-human-globulin serum reveals that the infant's cells have been sensitized by the action of the maternal antibody *in vivo*.

If anti-Rh agglutinins are present in the mother's blood they will also be excreted in the milk, but at somewhat lower titre. It is not advisable to allow the infant to suckle the breast, but if the mother's milk is abundant it may be withdrawn by pump, heated to destroy the agglutinin, and fed to the child. After a few weeks the agglutinin content usually falls to such a low level in the milk that it ceases to be dangerous and breast feeding may then be allowed.

After the first recognition of haemolytic disease in a family the blood of the father should be investigated for the Rh factor to determine whether he is homozygous or heterozygous for Rh. On this depends the future prognosis—a matter about which the parents are often more anxiously concerned than about the fate of a child recently lost. In our experience, parents are often ready to face the 50% chance of a normal child, but are less ready to produce a child if they know that haemolytic disease is almost inevitable. Where the father is known to be homozygous the prognosis is bad; a large number of subsequent pregnancies terminate in miscarriage or premature birth of a macerated foetus, for which no prophylactic treatment is of any avail. One cannot comfort the parents beyond expressing the hope that transfusion may save a proportion of such children if they are born alive, but the dread sequel of kernicterus must also be borne in mind, for in some cases it occurs in spite of early and repeated transfusion.

Haemolytic Disease where the Mother is Rh-positive

In about 10% of cases of haemolytic disease the mother is Rh-positive. There is no proof that there is any cause of this disease other than iso-immunization, and in such cases the aetiology usually lies in iso-immunization against one of the elementary Rh antigens which the mother herself lacks, but occasionally incompatibility of the ABO groups may be concerned. It is also certain that there are hereditarily transmitted red cell antigens other than those of the ABO, MN, P, and Rh systems, and on rare occasions such factors may be responsible for iso-immunization, but knowledge of these is still fragmentary (Callender and Race, 1946).

Two clearly defined types of iso-immunization in Rh-positive mothers may, however, be recalled—viz., the production of iso-antibodies of type anti-E (anti-Rh'') by mothers of genotype Rh,rh (Boorman, Dodd, Race, and Taylor, 1944) and the development of sera such as St (anti-c) by mothers of genotype Rh,Rh, (McCall, Race, and Taylor, 1944). In the 10% of Rh-positive mothers of affected infants, however, such antibodies are only rarely detectable, and failure to demonstrate iso-antibodies is the rule. In the majority of cases the husbands' blood groups are such that iso-immunization is theoretically possible. Thus in 12 of our 16 cases of haemolytic disease in Rh-positive mothers for whom sufficient data are available the fathers' blood contained a Rh antigen absent from the mother's cells in 8, and in four of these also an incompatible A or B antigen. In the four remaining cases without demonstrable Rh incompatibility the pregnancy was heterospecific in three, and in the fourth case, where both parents were Group C Rh,rh, the mother's serum contained an unknown irregular agglutinin (Cappell, 1944; Case 10) acting on the cells of the husband and affected child. In one other case the mother's serum contained an unknown irregular agglutinin, but in the remaining 14 cases irregular iso-antibodies could not be detected. In two cases of heterospecific pregnancy, the mother being of Group O and the baby of Group A, the maternal anti-A titre was unusually high in one (1:2,048), and in the other an active haemolysin was detected. Proof that the foetus suffers damage from the increase of maternal iso-agglutinin in heterospecific pregnancy is difficult, and with increasing knowledge of the complexity of the Rh groups fewer cases are now attributed to this cause. It is pretty certain, however, that ABO incompatibility was responsible for haemolytic disease in the cases reported by Boorman, Dodd, and Molliso (1944), in some of the cases in Rh-positive mothers reported by Plaut, Barrow, and Abbott (1945), by Polayes and Ohlbaur (1945), and by Austin and Smith (1946).

The direct application of Coombs's anti-human-globulin serum will in future enable us to detect *in vivo* sensitization of the cells of affected infants, and the indirect test will probably reveal iso-antibodies in maternal sera which do not yield irregular agglutinins. Thus Coombs, Mourant, and Race (1946) have demonstrated *in vivo* sensitization of the cells of an infant suffering from haemolytic disease, the infant and parents being all of Group O Rh,rh, and have shown that the mother's serum contained an unknown antibody against the husband's cells (the Kell antigen-antibody system).

In the treatment of the affected children of Rh-positive mothers the maternal blood group is the guide, and the child is given blood similar to the mother's on the supposition that

It will be unaffected by any kind of anti-Rh or other irregular agglutinin which the mother may have produced. The mother's whole blood should not, of course, be used, as its content of antibodies would aggravate the haemolytic disease. It is rational, however, to use the mother's red cells after centrifuging and thorough washing with saline to remove all traces of plasma. In most cases it is simpler to submit a sample of the mother's serum to the Blood Bank or Regional Transfusion Officer and receive a supply of carefully matched blood; but occasionally, when the nature of the iso-immunization is obscure, the use of the mother's washed red cells may be necessary to save the child. In such cases it is unimportant that the mother's cells may be of Group A or B and the child's cells of Group O; owing to the absence of the natural iso-agglutinins in the newborn child, other than small amounts derived from the mother, the maternal red cells, whatever their group, are always compatible with the serum of the child. It is very much more important to examine the mother's blood for its Rh type than the child's, for in all cases due to Rh incompatibility the infant if affected is Rh-positive. When a suspected case is sent into hospital a sample of the mother's blood must always go along with the affected infant, for if she is Rh-positive it depends upon her genotype what kind of anti-Rh she is likely to have made. Anti-d and anti-e have not yet been detected in association with pregnancy, but Rh-positive mothers have been found to make either anti-c or anti-E. Accordingly the routine transfusion of infants suffering from haemolytic disease with Rh-negative blood will occasionally fail to give the best result, for in those with anti-c such blood would be susceptible to the irregular antibody and would be less effective. It is for this reason that a sample of the mother's blood should always be sent to hospital along with the infant. The mother's serum is used to perform a careful cross-matching test with the blood to be administered to the child, both at room temperature and at 37° C., and with further experience of Diamond's open slide test this method may be helpful in detecting incompatibilities not readily demonstrated by other methods.

Summary

An account is given of the development of knowledge about the Rh blood group. The different types of human iso-antisera have been described and the consequent deductions as to the antigenic structure of the Rh factor have been pointed out. The nomenclatures applied by different workers in this field have been correlated and the need for clearer definition of "Rh-positive" and "Rh-negative" has been emphasized. While in the present state of knowledge Fisher's synthesis affords the most satisfactory explanation of the antigenic structure and mode of inheritance of the Rh group, it is suggested that Fisher's Greek letter terminology for the antibodies might advantageously be replaced by one based more directly on the hypothetical elementary antigens of the Rh complex—e.g., anti-C instead of Γ , anti-D for Δ , etc.

The types of clinical disorder resulting from iso-immunization by transfusion and in pregnancy have been presented and the pathogenesis of haemolytic disease of the newborn is discussed. Attention is drawn to the relative infrequency of haemolytic disease in heterozygous pregnancy. An outline is given of the management of a case of haemolytic disease, and the principles of treatment for the affected infant, both of Rh-positive and of Rh-negative mothers, are described.

I owe to thank Dr. Sheila Callender for a supply of anti-C serum, Dr. A. E. Mourant for a supply of anti-e serum, and Dr. R. Race for confirmation of serological findings in some cases. Dr. Marjory N. McFarlane has kindly put at my disposal the results of her observations in Dundee.

THE FENESTRATION OPERATION FOR OTOSCLEROSIS

BY

I. SIMSON HALL, M.B., Ch.B., F.R.C.P.&S.Ed.

Search for the solution of the problem of middle-ear deafness can be said to have begun in 1876, when Kessel demonstrated a transient improvement in hearing after extraction of the stapes. This was confirmed by other workers, and various attempts were made, by opening the labyrinth in different places, to prolong the improvement gained. The promontory was used by Kisch, and the semicircular canals by Bárány and others.

The modern operation was first suggested by Jenkins in London in 1913, for he appears to have then made an opening in the horizontal canal and covered it with a pedicle flap taken from the postero-superior wall, including the membrana flaccida. This is in principle the operation carried out at the present time. Fraser, of Edinburgh, experimented along the same lines, but he, like many other workers, was discouraged by the temporary nature of the results, and abandoned the operation on account of this and also because of the dangers involved. It was not till about 1917, when Holmgren of Stockholm started his work, that the operation was developed along modern lines and took its place as a recognized surgical procedure. To Holmgren must go the credit of having, by exhaustive and painstaking research, stimulated the interest of those surgeons who are to-day bringing fresh hope and happiness to many who have been pronounced incurably deaf. Following Holmgren a number of workers took up the study, including Sourdille in France, and Lempert, Kopetzky, and Shambaugh, to mention only three of many, in America. Owing to the exigencies of war opportunities for research have been curtailed in this country, so that the volume of work done in America has been very much greater, and large series of cases have been recorded there.

The present account records the results and impressions of ten years' work on several variations of the fenestration operation.

Principle of the Operation

The operation is believed to be applicable to cases of otosclerosis chiefly, for this disease, by causing fixation of the stapes, prevents the free movement of sound waves within the labyrinthine fluids. As the stapes becomes increasingly

immobile in the oval window the normal recoil of the fluid is impossible, and deafness of middle-ear type results. It has been found that if another opening is made in the wall of the labyrinth hearing immediately returns, presumably because the fluid within the labyrinth is again free to carry the vibrations of sound. Whether or not this will eventually be found to be the true explanation, the fact, which has been verified by every surgeon who has carried out the operation, is that at the moment of releasing the perilymph hearing returns with dramatic suddenness and intensity. It is this experience of the apparently miraculous which has encouraged perseverance in the face of repeated failure.

Selection of Patients

A great deal has been written on this aspect, and rules have been laid down for when it is justifiable to submit a patient to operation. It is quite evident that in the case of young people with only moderate hearing loss operation is the treatment of choice and should be advised, because a very high percentage of successful results can be obtained.

As age increases and other factors are introduced which tend to reduce the possibility of restoration of normal hearing, the problem of advising the patient becomes one of considerable complexity and one which cannot be solved by reference to a set of rules. The reasons which cause older people to seek help are economic, psychological, and social, and each of these factors must receive due consideration in weighing up the necessities of the case. Every worker of any length of experience in this operation has at some time or other been surprised and gratified by success when little was expected, so that it is to be doubted if anyone can state categorically whether in these borderline cases help can or cannot be given. And, further, so long as there is evidence, as there seems to be, that operation can retard or for a time prevent further deterioration of hearing, great benefit can be given to those of poor hearing by keeping them just within an economic level. We see, therefore, that there are many whom we can accept for treatment without hesitation and many whom we can judge are better served with a hearing aid, but there are also those who can be advised only after the most careful and sympathetic consideration of every aspect of their problem.

So long as these doubts and problems remain selection of a certain number of patients for purposes of observation must be made, even though it may mean that tables of results will not look as favourable as they otherwise might. For the best results the patients should be young—preferably under 25 years—there should be neither sign nor history of middle-ear disease, there should be no nerve deafness, and the hearing loss within the speech range should not be greater than forty to fifty decibels. Under these conditions the operation should give over 80% of immediate success.

Preparation and Anaesthesia

The general preparation of the patient is the same as for any major operation, while the local preparation is that used for a mastoidectomy. The only addition to the usual routine is that great care is taken to cleanse and sterilize the external auditory meatus.

The operation can be done under general anaesthesia or local analgesia, according to the preference of the operator. The advantage of local analgesia is the comparative bloodlessness of the field; the chief disadvantage is the extremely heavy premedication which is necessary if the patient is not to suffer from the very unpleasant symptoms induced by the opening of the labyrinth. The use of a general anaesthetic as the main agent gives the operator complete freedom of action and an immobile and indifferent patient, while the added tendency to bleeding can be minimized by haemostatic injection. After trying many forms of anaesthesia the one now used is morphine-atropine premedication with intratracheal cyclopropane-and-oxygen insufflation. This is varied on occasion with light ether or gas-oxygen administration, or with intravenous pentothal infusion. Anaesthesia by methods such as these can be prolonged as required without detriment to the patient.

A great deal will be found to depend upon the skill available for administering the anaesthetic, and every operator will have to suit his method to the conditions under which he works.

Apparatus

Apart from the usual instruments required for a mastoidectomy there must be a means of cutting an opening measuring in millimetres, and for this a dental drill is most commonly employed. A magnification of at least three times is needed and more if possible. With the apparatus at present employed a magnification of six times and more is used, through a dissecting microscope, which allows greater power for any special part of the operation. Illumination is obtained from a lamp fixed to the microscope, and it is important that the light should be good. Irrigation, either continuous or intermittent as desired, is used to wash away any bone dust, to keep the field clear of blood, and to act as a sterile barrier between the open labyrinth and possible infection from the air.

Technique of Operation

The operation follows the lines of the modified radical mastoid procedure in the exposure of the labyrinth, except that, as suggested originally by Jenkins, a flap is cut from the posterior and superior aspects of the external meatus such a manner that it remains attached to the membrana flaccida forming a pedicle flap with the lower edge of that membrane as its hinge. This flap is eventually turned over the attic floor and made to cover the new opening into the vestibule.

The formation of the flap is of the greatest importance; if it is torn seriously, so that there is doubt whether the opening will be properly covered, then the operation will have to be abandoned. Happily this does not mean complete failure, for at a later date the operation can be completed as a two-stage procedure, without prejudice to the final result. The incus and the head of the malleus are removed to complete the exposure of the vestibule just as they are removed in the mastoid operation, when found to be diseased.

The method of approach to the middle ear has been a subject of some discussion, but the conclusion has been formed that it is immaterial whether the post-auricular or the external canal route is used. In either approach the soft parts can be moved and manipulated to give equal access to the attic floor. The factors which control the approach are the angle which the external bony meatus makes with the drum membrane and the height of the attic roof, which as a rule is equivalent to the position of the dural plate of the middle fossa. Problems of lighting, magnification, and irrigation lend themselves more easily to solution by the post-auricular route.

After exposure of the vestibule the new opening is made as far forward on the horizontal canal, where it enters the vestibule, as the thickness of the bone will permit. The object is to make the opening over the ampulla, but as the angle of the vestibule varies within quite wide limits and the depth of the bone causes considerable variation in the position at which the new fenestra can be made, it is not possible to determine within fine limits where the opening will be made until the canal is opened. With various burrs the bone is thinned until the vestibule is defined, and finally the bone covering with the endosteal layer is fragmented and removed, exposing the membranous tube of the horizontal canal as it passes downwards into the body of the vestibule. It is customary to polish the saucer-like depression, and to remove all fragments of bone and endosteum, with specially designed instruments resembling dental excavators. The removal of the endosteum is probably of much greater importance than polishing, as the regeneration of bone takes origin from the endosteal layer, starting from the canal and passing forward over the roof of the vestibule. This has been seen clearly in revising fenestrae which have closed by new bone formation. It is the prevention of this closure which is the crux of the operation, as the gradual disappearance of the fistula usually means progressive loss of the regained hearing.

When the new opening has been made to the satisfaction of the operator the flap is spread over it, with care to prevent the insertion of cartilage or other substance designed to prevent closure by bone. The flap is fixed by means of sutures and the wound is closed as in any mastoid operation. The after-treatment follows the usual lines—that is, the dressing is carried out after about a week and the cavity is irrigated to maintain sterility and obtain the most rapid epithelialization of the cavity. Complete healing is of the utmost importance.

continued discharge or infection will go far to ruin a successful operation. Healing occurs in from six to twelve weeks—often the latter.

Progress after Operation

In the successful cases there is an immediate and dramatic increase in hearing the moment the labyrinth is opened: this can be demonstrated when the operation is done under local anesthesia. This improvement has on occasion been so great that the noise has distressed the patient and sedatives have been required until adjustment to the new conditions was achieved. The average case the hearing deteriorates on the second or third day to its previous level, to improve again slowly up to a time when the ear is completely healed, when as a rule it is at its best.

Signs of labyrinthine disturbance are immediate from the time of opening the canal and may be severe, but they are not likely to persist for more than three days, unless the patient improves quickly. Thereafter readjustment proceeds steadily, although it varies greatly in different individuals. Some take many weeks to reach the stage of complete confidence, while others have little or no disturbance. Those accustomed to mental and physical exercise have much less difficulty than those of more sedentary habits.

Other Sequelae

Apart from the effects upon hearing and balance several other interesting phenomena have been observed. Confusion of sounds is the rule, and the patient has to undergo a re-education to distinguish speech in the volume of noise with which he or she is surrounded; but in some instances this confusion becomes a complete reorientation of sound, so that there is reversal of the normal, and footsteps, street cars, and the like are heard behind the patient when the origin of the sound is in front. On occasion this may prove a frightening and disturbing experience.

Difficulty in accommodation has been a complaint on several occasions, and lack of co-ordination has been greater in some patients than could be accounted for as a normal effect of a serious operation. Happily all these effects have disappeared without any sign of permanent disability.

Causes of Failure

Failure to bring about any improvement may be due to selection of unsuitable cases. Technical failure probably plays some part, but it must be very small, for in this series there was only one case, and in this the complete failure of the electrical supply probably contributed to lack of success. Hitherto undiagnosed disease was present in one patient, in whom appearances within the labyrinth were strongly suggestive of previous inflammation. Infection of the cavity was formerly one of the most dangerous conditions so far as hearing was concerned, but since the introduction of sulphonamides and penicillin its importance has greatly diminished.

Acute otitis media has been encountered, but experience has shown that it is not necessarily disastrous. Pregnancy has occurred in several patients, and its effect has been variable: in some cases there has been a definite fall in hearing, but others have been unaffected. In all cases of late failure the most important cause has been closure of the new opening, evidenced by the gradual disappearance of the fistula sign.

When the fistula becomes more difficult to identify the hearing wishes, and where the fistula sign cannot be obtained the hearing as a rule has returned to its former level. To combat closure of the fistula many expedients have been devised, particularly by Holmgren. One of the most promising suggestions is the use of a cartilaginous implant, or "stopple," and from Lempert of New York. My experience of this method extends to about ten months only, so I can give no opinion on the final value of this idea. The impression gained, however, of the immediate results is that they are as good as in cases done without cartilage. As no considerable improvement more than two years' duration appears to have been made, final judgment will have to be postponed. The statement that the usual post-operative loss is lessened by the use of this implant has not been confirmed here. Should this method stand the test of time and experience it will prove to be the solution to the main problem.

Results of Operation

The total number of operations performed is just over 200, and of these 118 consecutive cases have been selected for analysis. This group excludes the earliest operations and the most recent ones, for it would be of no value to include cases performed with primitive equipment in a series done with modern methods; and as it is found by experience that a certain number of patients suffer an early deterioration of hearing, those operations carried out during recent months are also excluded. Although five months is the period usually allowed, in this series more than eight months has been taken, and no case is included which has been operated upon during the year 1946.

Of the 118 cases 82 are still improved, giving a total percentage of 69. As this figure includes patients of all ages—suitable and unsuitable cases and some accepted purely for observation purposes—it means very little, and does not give a true picture of what can be done. The following table of results according to age groups is more informative:

Age ..	-19	-24	-29	-34	-39
Improved ..	80%	77%	70%	62%	61%

This demonstrates the diminishing probability of success as age increases. It is noteworthy, however, that in the "over 40" group a higher proportion of success has been obtained—nearly 80%—owing to very great care in selection, but as this is not representative of what can be done with the general run of cases of progressive middle-ear deafness at this age it is not included in the table.

There is no doubt that with increasing knowledge of the factors affecting success and failure, and by confining the operation to the favourable groups only, a high figure of success could be produced. To so limit the application, however, would be, at least in the present state of our knowledge, to inflict hardship upon many who might obtain benefit, while included among the failures are some who are proved by the audiometer to have remained stationary at the level at which they were before operation. This is a result of great importance to the patient in a disease which is almost always progressive.

There has been one case of facial paralysis which recovered completely, and there have been no cases of labyrinthitis. Two fatalities occurred in this series: one patient, an elderly woman, died of acute cardiac collapse shortly after the operation was completed; another, a man aged 43, died of acute morphine poisoning some hours after the operation on receiving the usual post-operative sedative. Although neither of these occurrences can be attributed to the operation itself, it must be emphasized that it carries all the dangers of a major surgical procedure and should never be embarked upon without every precaution being taken for the patient's safety.

If the patient therefore can appreciate the risks and the uncertainties involved, he alone must make the decision for or against operation. To enable him to do this all available information must be laid before him frankly and fully.

Summary

The purpose and the indications for the fenestration operation are described.

The method of carrying out the operation is briefly given and reference is made to the equipment necessary for its performance.

The effects of the operation are discussed and the results in a series of 118 consecutive cases are detailed.

It is considered probable that, with an increasing knowledge of the subject, a high percentage of successes could in suitable cases be obtained.

PITUITARY HYPOTHYROIDISM WITH IMPAIRED RENAL FUNCTION

BY

R. A. MILLER, M.D., F.R.C.P.Ed.

(From the University Department of Child Life and Health,
Edinburgh)

In 1943 Beaumont and Robertson described a syndrome called "pituitary hypothyroidism with impaired renal function." The term was applied to a patient who had signs and symptoms of thyroid deficiency and a subnormal urea clearance, impaired water elimination by the kidneys, and inability to pass a high-specific-gravity urine. So far as can be ascertained, there has been no previous record of such a syndrome in medical literature. After this syndrome was recognized, it was proved experimentally that hypopituitarism produced in dogs by ablation of the anterior lobe of the pituitary was followed by a diminution in the urea clearance (Pickford and Ritchie, 1945).

The development of hypothyroidism is dependent upon a degenerative process in the thyroid gland or a pathological condition of the pituitary body. If it be the latter, the lesion may be a neoplasm or degenerative process of the hypophysis, or secondary to a space-occupying lesion in any part of the brain. The clinical picture of the resulting hypothyroidism is one of inertia and retardation of all mental and bodily functions; the individual appears indolent and expressionless, although his intellectual capacity is only slightly impaired, if at all. The hair becomes scanty, the skin dry, the eyelids puffy, and the palpebral fissures narrow. The patient complains of being persistently cold, and his body temperature is as a rule subnormal, basal metabolism low, blood circulation retarded, blood cholesterol high, and heart enlarged (Zondek, 1944).

The first known account of pituitary hypothyroidism with impairment of renal function due to a head injury is reported below, together with a differential diagnosis and discussion.

Case Record

A soldier aged 23 was wounded with shrapnel on Feb. 15, 1945. The shrapnel produced a large right fronto-temporal skull defect, destroyed most of the underlying frontal pole of the brain, and rendered him deeply unconscious, mentally confused, or disorientated in time and space for four months. Shortly after he became cognizant of his whereabouts his intellectual capacity was above the average, but his mental processes were retarded and he lacked initiative and interest in his surroundings. He preferred to sit in a hot atmosphere to get warm rather than to lead an active existence. His general health was fairly good, but his appetite was poor, and his weight fell 3 stone (19 kg.) during the first few months of the illness. There was no evidence in his history of other bodily disease.

Physical examination throughout the first nine months of illness showed the following abnormal features: a temporary subnormal temperature, a right fronto-temporal skull defect which was made good with a tantalum plate on Aug. 9, 1945, and scars on the forehead, the right side of which also showed impaired sensitivity to pinprick. He had right-sided hyposmia and his right eye was absent. On the left side the eyelids were puffy and the palpebral fissure narrow. There were no other abnormal signs at the time of his discharge from hospital in December.

Tests showed that he had no albuminuria or glycosuria, and microscopically and bacteriologically his urine was normal. The specific gravity of the urine was 1004 to 1030, but was higher during the day than at night. His water secretion (Dec. 5 and 6) in two hours after drinking two pints (1.14 l.) of water was 12 to 13 oz. (340-368 ml.). In December, 1945, his urea clearance was 48% normal, and blood urea 29-35 mg. During the same month his glucose-tolerance test was normal, but his basal metabolic rate was subnormal (-21).

Differential Diagnosis

In the above case the abnormal signs, symptoms, and laboratory tests are compatible with the diagnosis of hypothyroidism due to a head wound. As there was no evidence of thyroid deficiency or any other disease prior to the localized injury to the head, an intracranial lesion involving the pituitary body is believed to be responsible for the hypothyroidism. No other intracranial lesion is known to give a similar picture.

Although pathological conditions in many parts of the body, such as heart failure, nephritis, Addison's disease, etc., may

also show a low basal metabolic rate and impaired retention, their characteristic features were lacking in the case history, physical examination, and investigations possible, however, that Simmonds's disease may have been present during the early months of the patient's illness, certainly not later on, for at that time there was no hypogonadism, low blood sugar, or increased sugar tolerance.

Discussion

The features in the preceding case record which explanation are the rate of water elimination and the clearance by the kidneys. Investigations of these features were made during the eighth and ninth months of the patient's illness. Between Oct. 24 and Nov. 14, 1945, the volume of each specimen of urine was measured and the specific gravity taken. The amount of urine passed in 24 hours was found to be within normal limits and the quantity secreted during the day was almost invariably less than at night, which is the reverse of normal (Kolmer and Boerner, 1938). This suggests that the patient ate or drank between 10 p.m. and 8 a.m. As this did not occur an alternative explanation of abnormal output of urine is that it is due partly to failure of pituitary hormonal control, and to some extent to change of posture.

The part played by hormones in the production of oliguria and nocturnal diuresis in pituitary hypothyroidism is perhaps analogous to the effects of pregnancy upon renal function. In the pregnant woman the rate of urine flow is more than half that of healthy women who are not pregnant. The blood volume in pregnancy is increased. Water is held by the tissues and not presented to the kidneys for excretion during the day, but at night the water stored in the tissues is excreted (Theobald, 1946). The hormones which could produce the diuresis are the trophic, elaborated by the anterior pituitary, and the thyrotrophic secreted by the thyroid gland (Beaumont and Robertson, 1943). As it is not possible to explain the alternating oliguria and polyuria on a hormonal basis an additional factor must be sought. The one applicable in the present case of pituitary hypothyroidism is change of posture.

The influence of posture upon urine output has been observed in normal people after they have drunk a litre of water. They will pass an equal volume of urine quicker when they are lying than when they are standing still (Theobald, 1944). The same is not true should the individual be up and physically active. The upright posture is also partly responsible for oliguria in patients with congestive heart failure because from the systemic circulation accumulates in the lower extremities as occult oedema and is not available for excretion by the kidneys (Fishberg, 1940). Therefore it is probable, that the abnormal rate of water excretion by the kidneys in pituitary hypothyroidism is due to an endogenous dysfunction and variations in posture.

As a rule a van Slyke urea-clearance test of 48% normal is due to renal disease, but in the case under discussion there is a history suggestive of illness referable to the urinary system. There was no polyuria, albuminuria, or abnormal constituents in the urine deposit. The specific gravity of the urine was from 1004 to 1030, and the blood urea and blood pressure were normal. In view of these findings the subnormal urea clearance is almost certainly extrarenal in origin (Fishberg, 1940) and could be accounted for by pituitary hypothyroidism (Beaumont and Robertson, 1943), which was the dominant feature in this case. The action of thyroid upon the urea clearance has been demonstrated by Beaumont and Robertson (1943). They showed that thyroid administration to myxoedematous people resulted in an improvement in the urea clearance. The fact that thyroid therapy cannot remedy the impaired urea clearance in cases of myxoedema shows that an additional factor is responsible for the poor clearance, and it is suggested that the oliguria in the present case may play a part in producing this effect.

The third abnormality in renal function is the high specific gravity of the urine during the day and the low at night. The figures were arrived at by measuring the specific gravity of every specimen of urine passed, including those at 1 and 4 p.m. The inverted day/night ratio for the specific gravity of

rine is in keeping with the inverted day/night ratio for urine output. Why the highest specific gravity urine was passed during the day and the lowest at night remains obscure, but the cause is probably the same as for the daytime oliguria and nocturnal diuresis.

Summary

A case of pituitary hypothyroidism with impaired renal function due to a penetrating wound of the brain is here reported. The renal abnormality consisted of a diminished urea clearance and an inverted day/night ratio for urine specific gravity and urine output.

Discussion was devoted to the abnormal renal function, which was considered to be partly due to hormonal dysfunction and partly dependent upon change of posture.

I am indebted to the Medical Director-General of the Army for permission to publish this paper and to Col. Roche, who allowed me to study the recorded case in his hospital. I would also like to acknowledge Dr. Ritchie Russell's encouragement and assistance in writing the article.

INCIDENCE OF ULCER IN HAEMATEMESIS

BY

ERNEST H. CLUER, M.R.C.S., L.R.C.P.

Resident Medical Officer, Albert Dock Hospital

It is generally accepted that the most common cause of haematemesis is peptic ulceration, either gastric or duodenal. In a series of 382 cases reported by Natvig, Römcke, and Svaar-Seljesaeter in 1943 radiographic confirmation was obtained in every case; 230 cases were of duodenal ulcer and 152 of gastric ulcer. McCrae (1938), although he gives no figures, states that "in medical practice haemorrhage from the stomach occurs most frequently with ulcer of the stomach or duodenum and from oesophageal varices."

In a small series of cases admitted to this hospital during the last three years, primarily for acute haematemesis, whatever the underlying pathology, only 7 (39%) of 18 patients were found to have radiographic confirmation of peptic ulceration.

Immediate treatment adopted in each case was along the customary well-established lines—i.e., the treatment of acute post-haemorrhagic shock. Morphine gr. 1/4 (16 mg.) with atropine gr. 1/100 (0.65 mg.), both repeated four- or six-hourly as necessary, elevation of the foot of the bed, covered hot-water bottles, half-hourly recording of the pulse rate with repeated blood-pressure estimations, blood counts and blood grouping at the earliest possible opportunity, were some of the immediate measures adopted. Small drinks of sweetened fluids were allowed in most cases if vomiting ceased soon after admission. Where it was apparent that bleeding had stopped, as evidenced by the return to normal of temperature, pulse, and blood pressure, the recognized Wits (1937) modification of the eulengracht two-hourly dietetic regimen (so far as wartime conditions would allow) was instituted, together with full doses of iron, phenobarbitone, magnesium trisilicate and belladonna tincture, and adequate vitamin dosage. The iron was administered in the form of ferri et ammon. cit., gr. 30 (2 g.) thrice a day, and was continued long after the patient was discharged as out-patient "follow-up" department. It is interesting to note that this quite simple medication was all that was necessary to produce the desired haemopoietic effect, and the clinical picture improved steadily week by week.

cases did well on this routine, and the average duration of admission in hospital was about five weeks. Three months after a barium meal was taken, the patient being screened, the radiological conclusions were as follows: chronic gastric ulcer, 5; chronic gastric ulcer (confirmed by gastroscopy); 1; anastomotic ulcer (confirmed by operation), 1; a total of 7 (39%). Two cases (11%) gave histories

suggestive of peptic ulceration, but no radiographic evidence of this could be obtained. In these circumstances I feel it is reasonable to assume that the diet, rest in bed, and medicines were responsible for complete healing of the ulcer and subsequent negative skiagrams. Two further cases (11%) proved later to be due to cirrhosis of the liver, where it is probable that the haematemesis were the result of ruptured oesophageal varices or congestion consequent on portal obstruction. One patient in the series had hypertension with severe epistaxis, and it must be concluded that some of his haematemesis, if not all, was caused by swallowed blood.

Gastric Erosion as a Cause of Haematemesis

The most interesting proportion is that of six patients (34%) from whom no history of dyspepsia could be elicited and who were perfectly fit up to or just before the time of haematemesis. In all these cases, after an uninterrupted recovery when treated along the above lines, a later x-ray picture revealed a perfectly normal stomach and duodenum. Fractional gastric analyses also performed at a later date showed no gross abnormalities, although some hyperchlorhydria was recorded in one case. In the absence of any other positive clinical or pathological findings it was concluded that these must have been acute gastric erosions. Avery Jones (1944) has stated, "Of 337 patients admitted for haematemesis and melaena, over half of whom were gastroscopied usually in the first week, seven were thought to have active gastritis to account for their bleeding." Jennings Marshall (1944) has expressed the view that "haemorrhage is an occasional manifestation occurring from superficial erosions. It may be brisk but is never severe or prolonged in such cases." Our small series tends to confirm this observation in that not one of our six "erosions" required a blood transfusion.

Horace Evans (1944), in discussing the treatment of duodenal ulceration, states that "the diagnosis of duodenal ulceration is in most patients relatively easy and confirmation by x rays satisfactory. The frequency with which complications, such as haemorrhage, perforation, and even stenosis, occur in patients who have minimal symptoms of indigestion is surprising, though no doubt in some this is due to the ulcer being of the more acute type. This type of ulcer or superficial erosion may heal with very little residual deformity, and so reveal no x-ray change soon after a haemorrhage."

In such a relatively small selection of cases one can hardly regard these conclusions as being of particular significance, especially when the primary treatment of haematemesis due to acute erosion remains identical with that due to chronic ulceration. It would, however, be most instructive to learn whether the incidence of acute gastric erosion is actually as high (34% of all cases) in larger hospitals as it has been found here. The proportion of admissions for acute haematemesis in this hospital is approximately 1 in 50, and it would therefore take many years to collect a comprehensive enough series to be worthy of consideration. If this could, however, be undertaken at hospitals where the number of admissions for haematemesis is higher, further light may be thrown on this interesting observation.

I wish to thank Sir Philip Manson-Bahr, senior physician to the hospital, for permission to use his cases, and for his kindness and assistance throughout the preparation of this paper; and Dr. F. G. Wood, honorary radiologist to the hospital, for the radiological reports.

The latest report of the Royal Hospital for Sick Children, Glasgow, states that 6,000 in-patients were treated during the year, and 70,000 out-patients, but adds that the work done was not up to what the hospital is capable of doing in normal times, with proper facilities, towards meeting the needs for medical, surgical, and specialist treatment of children in the centre and west of Scotland. "The infantile mortality rate in Glasgow is terribly high. It is the business of such a hospital as this to investigate the causes and find a cure."

Medical Memoranda

A Case of Clicking Ears

Though subjective sensations of noises in the ears are common enough, the emanation of sounds audible to others seems a phenomenon worthy of record.

CASE REPORT

The patient, a British soldier aged 22, was sent into an Indian psychiatric hospital because of nightmares in which he flung himself about and called out for a rifle. They had occurred for twelve months, and appeared to be related to experiences under shell-fire and V.I. bomb attacks in 1944. They ceased following two pentothal sessions and other psychotherapy. He also drew attention to a clicking noise which was audible to himself and others, and which he first noticed three months ago, 24 hours after a football had hit him on the cheek. The noise was heard when the observer placed his ear a few inches from the patient's; it resembled the soft crackle of an electric spark. Each click was a short distinct noise which was repeated at slightly irregular intervals at an average rate of from 24 to 32 a minute. The clicks were synchronous in the two ears, and bore no time relation to the pulse, respiration, movement of the mandible, or swallowing; the drums were never seen to move, and the clicking was unaltered when the meatal pressure was raised or during Eustachian catheterization. Major Clark, otorhinolaryngologist, examined him, and reported that the hearing, the appearance of the drums, and the Rinne and Weber tests were normal. The nasal airway was clear, though there was slight deviation of the septum to the right. The Eustachian tubes were patent. Over a period of two months' observation the sound was never absent when listened for except under pentothal or during sleep, when it ceased; the patient said that he could always hear it if he directed attention to it, though he noticed it chiefly at night. Complete physical examination and radiography of the skull were normal.

The patient gave the history that when he was 6 he developed a facial tic; he blinked his eyes, and screwed up his nose to one side. The condition lasted two years. When he was serving in B.L.A. he noticed that he was blinking excessively.

COMMENT

Spasmodic contraction of the stapedius or tensor tympani muscles analogous to facial tic appears the most likely cause of the phenomenon.

ELLIOTT EMANUEL, B.M., B.Ch., D.C.H.

A Case of Infectious Mononucleosis Requiring Tracheotomy

Shirley Smith and Shaw (1945) have reported dramatic improvements in several cases of anginous glandular fever after injection of neoarsphenamine. In the case reported below the rapid disappearance of fever, angina, and adenopathy after the injection strongly suggested a specific effect. The asphyxia attack—presumably due to oedema of the glottis—occurred twelve hours after the injection. It is felt that it may have been precipitated by a process analogous to the Herxheimer reaction.

CASE REPORT

A previously healthy soldier aged 20 was admitted to hospital on Nov. 17 complaining of sore throat and malaise of three days' duration. On examination he was febrile but did not look unduly ill. The throat was generally inflamed, and there was a patchy exudate on both tonsils. The most striking feature was a gross enlargement of all the cervical lymph glands, producing an appearance of "bull neck." A tentative diagnosis of glandular fever was made, but it was felt that antidiaphtheric treatment should not be withheld. Accordingly, 48,000 units of antidiaphtheria serum were given intravenously, and a course of intramuscular penicillin begun, with an initial dose of 50,000 units followed by 20,000 units three-hourly for three days. A throat swab taken on admission grew only non-haemolytic streptococci.

During Nov. 18 and 19 there was no response to specific treatment. Nasal obstruction developed with a mucopurulent discharge from the right nostril. The cervical lymph glands became even larger, and in addition tender glands appeared in the axillae and groins. The spleen was not palpable. Fever persisted, the temperature rising to 103° F. (39.4° C.), and the patient became restless and confused. The urine now contained a gross amount of albumin but no casts. Throat and nose swabs taken on the 19th grew only non-haemolytic streptococci. A white blood count done on the same day gave a total of 11,500 (polymorphs 53%; lymphocytes 20%; abnormal cells of mononuclear origin 22%, showing pseudopodial projections and indentation of the nucleus).

During Nov. 20 and 21 there was little change in the physical signs, but the patient's general condition deteriorated, and he became disorientated and incontinent of urine. A further blood count gave the following results: R.B.C., 5,100,000; Hb., 15.4 g. per 100 ml.;

W.B.C., 15,400 (polymorphs 37%; lymphocytes 16%; al cells 47%, showing a foamy cytoplasm, coarse granules, pseud etc.). On the 21st there was little change in the patient's condition. Breathing was not unduly laboured, and it was decided to give an intravenous injection of neoarsphenamine, 0.45 g., at 5.3 the urine then contained only a faint trace of albumin and no There was no immediate reaction.

At 5 a.m. on the 22nd the patient developed respiratory and rapidly became completely obstructed. Emergency tracheotomy was performed by Lieut.-Col. Jelly, R.A.M.C., at 5.45 a.m. at which time breathing had ceased and the pulse was scarcely perceptible. After artificial respiration had been performed condition of the patient rapidly improved, and within six he was conscious, rational, and could breathe easily past the tube. The cervical glands subsided rapidly and were noticeably softer the touch. On the morning of the 24th the tube was removed. Temperature and pulse had dropped to normal and remained so. The throat was clear of exudate and the adenitis was resolving. Thereafter recovery was remarkably rapid and complete. Serum taken sixteen days after the onset gave a positive Paul-Johnson reaction to a titre of 1/256/trace/512.

Thanks are due to Col. J. J. Biggam, M.C., late R.A.M.C., Officer Commanding, 84 Military Hospital, B.A.O.R., for permission to publish the case. Lieut.-Col. A. C. Dornhorst, R.A.M.C., Officer Commanding, Medical I 84 Military Hospital, for his help and interest.

Acute Appendicitis and Direct Inguinal Hernia

An acutely inflamed appendix lying in any hernial sac is quite infrequent occurrence, but still more rare is its association with the uncommon type of direct inguinal hernia.

CASE REPORT

A healthy man aged 40 was admitted to the Royal Infirmary, Edinburgh, in June, 1943, with a history of five days' general intermittent abdominal pain and nausea. The day previously it had become worse and settled in the right iliac fossa, but the pain was acting regularly. A firm, rounded, tender swelling about (2.5 cm.) in diameter was palpable on the right side 1½ in. (3.8 cm.) superior to the inguinal ligament and near the internal inguinal ring. It could be grasped between the finger and thumb except for its site, resembled a small strangulated femoral hernia. It did not pass as far down as the external ring and was irreducible. There was slight tenderness in the right iliac fossa, the tons slightly furred, and temperature, pulse, and respirations were normal. The diagnosis was not certain: appendicitis, inguinal hernia, Richter strangulation, and glandular enlargement were possible.

Operation was performed under spinal analgesia, and the skin incision for an inguinal hernia was made. When the sac was adequately exposed it was found to be unconnected with the internal inguinal ring, lying medial to the deep epigastric artery. It was a short, congested, direct inguinal hernial sac. A small amount of omentum was found adhering to the fundus of the sac, which was wrapped around an acutely inflamed appendix. This was removed via the sac, which was then excised. The herniation had placed through a localized opening with firm edges (about 2 cm. diameter) in the transversalis fascia. An uneventful recovery took place.

COMMENT

Ogilvie (1937) was probably the first to describe a rare type of direct inguinal hernia, which consists of a tubular hernia of peritoneum emerging through a circular deficiency with tendinous margins in the transversalis fascia medial to the epigastric artery. Gill (1939) reported three cases and a fourth, the bladder wall being present in some and a Richter strangulation in one, while MacLeod (1939), Warren (1939), Dodd (1939), Wimberger (1939), Dorling (1939), and (1943) recorded about a dozen more. The occurrence of appendicitis in a hernial sac has been recorded more often than forms about 1% of all herniae (Wakeley, 1938). This illustrates the association of two uncommon conditions and a reference to a previous case has been found.

Edinburgh.

Reviews

WORLD HUNGER AND F.A.O.

The World's Hunger. By Frank A. Pearson and Floyd A. Harper. (Pp. 90. 11 50 or 9s. 6d.) New York: Cornell University Press; London: Oxford University Press.

The first aim of the Food and Agricultural Organization of the United Nations is "food and a health standard for all the people of the world." There are difficulties in the achievement of this aim that we may feel have not been examined fully. The Hot Springs Conference declared that the first cause of hunger and malnutrition is poverty. The fundamental problems are to raise the purchasing power of consumers and to apply the capital for developing agriculture in backward areas. hitherto purchasing power in the more developed countries has not kept pace with production. It is questionable whether any of the social schemes that have been proposed will raise purchasing power sufficiently. Unless the proposed World Food Board adopts a restrictive policy it may well become saddled with ever-growing surplus stocks that it can dispose of only through an expanded U.N.R.R.A. The improvement of backward types of agriculture involves investments which may well be unremunerative to the investors and the possibility that the investors may be able to dominate the economy of the countries in which agriculture is developed. We have, however, felt little doubt about the possibility of producing the food necessary to maintain a satisfactory level of nutrition.

The authors of *The World's Hunger*, Professors of Prices and Statistics and of Marketing at the New York State College of Agriculture, Cornell University, have attempted "to present some facts about the food habits of the world's two billion people, about their differing habits, about the production of food and the prospects for its increase, and about the possibility of upgrading food habits." About half the book is occupied with surveys of production, trade, and consumption (including food habits), of the physical conditions which make land suitable for agriculture, and of physical geography (not excluding the age of the earth) which are, inevitably, superficial. Their sole value is in showing that a great increase is needed in order to attain the scales of consumption that are recommended and that the area available for the production of food is limited. The authors mention the risks of investment in irrigation and tell us that much of the land that has been irrigated has not paid its original cost and gives no promise of doing so, and leave it at that. It would be useful to know what is the proportion of this land to the total that has been irrigated and whether causes such as the underconsumption and resulting depression of 1929 and the early thirties have not contributed to the failure.

At the end of the chapter on production, trade, and consumption the authors state: "There is no shortage of schemes and plans for upgrading the world's diet. There is shortage of programmes containing down-to-earth methods of attaining this laudable aim." This is flatly untrue. Many practical methods of increasing the amount of food produced have been worked out and are being applied. In the second half of the book the authors mention some of these without, however, making any attempt to calculate how much each or all together might add to the world's food supply. They make no mention either of the control of pests and diseases or of the restoration of and damaged by erosion; yet the methods and organization that have been developed in recent years, with these objects, promise to add considerably to our supply of food. Livestock give a poor return in terms of calories for the food that they eat; the authors fear, therefore, that if the supply of animal products is increased the total calories will fall below requirement. They have missed the point that when land is devoted to the production of cereals its fertility declines, and that mixed farming may give a better yield even in terms of calories. Nor do they take into account the enormous amount of food that is at present consumed by non-productive livestock, from the cattle in India to rats and locusts.

In connexion with the possibility of increasing the production of food the authors might study the report of the U.S. Agricultural Department: "The increase in total production

from 1939 to 1944 was twice as large as during the entire 20-year period from 1919 to 1939. This wartime record was accomplished without a significant expansion in acreage, and despite insufficient supplies of labour, machinery, and other materials." Thirty years or more ago yields of wheat in Montana and the Dakotas oscillated between 3 and 60 bushels to the acre. There has now been a long interval without a crop failure, owing to the conservation and good use of water and the use of improved varieties of wheat. This is an example of the down-to-earth methods which are being used all over the world.

This book makes no contribution to the solution of the world's food problems. The authors adopt a hostile attitude towards those who wish to raise the standard of nutrition which is not justified nor even explained by any erudition that they display.

PAPWORTH FAMILIES

The Papworth Families: A 25 Years' Survey. By E. M. Brierley, M.D. With a preface by Sir Arthur MacNally, K.C.B., M.D. (Pp. 674. 45s.) London: William Heinemann.

Preventive action with a child born into a tuberculous family may take three courses: separation, BCG vaccination, or improvement in the home environment. The Papworth Village Settlement has provided experimental conditions that help in answering the question: Can a high standard of home environment and hygiene (affecting resistance of the individual and intensity of contagion) offset the effect of the presence of an infective source, and possibly also of hereditary predisposition? The germ of Dr. Brierley's painstaking survey is the elucidation of this relationship, but there is a wealth of general information upon the contact-factor in tuberculosis. After an historical introduction on this factor in the pathogenesis of the disease, there comes the survey proper, based upon the records kept by Dr. L. B. Stott from 1922 to 1938 (the detailed family case-histories occupy more than half the book) of 260 children born before the entry of their families to the settlement, and of 108 born in the settlement. Special interest attaches to the group of 50 Village-born children of sputum-positive cases, none of whom, up to an average age of 5 years, had developed active childhood tuberculosis, though latent benign changes, including calcification, were evident in some. A similar freedom from serious disease was found in the Village-born children of sputum-negative cases. The conclusion is that "in these Village-born children, Papworth has apparently succeeded in securing an environment on which exposure to intra-familial infection has not succeeded in producing active lesions." Furthermore, "a comparison of the incidence of lesions in Papworth-born children with the incidence observed in admitted children, exposed before the age of four years and prior to admission, showed that the Village-born children have to be classed in a specially privileged group with regard to contact infection" (p. 148). So it would appear that, within limitations, the question posed above is answered in the affirmative. The limitations are the small numbers, the low average age of the children to date, and the consequent lack of opportunity to study the possible incidence of adult-type phthisis, and the absence of recent tuberculin tests. The continuation of this survey on the lines indicated by Dr. Brierley's work is thus desirable, and as the end-date of his review is 1938, the further work might well be started forthwith.

The findings, if confirmed on larger numbers and for longer periods of observation, will not only show what a well-run village settlement can do for the children of a very small part of the tuberculous community; they will underline the importance of general schemes of social assistance to tuberculous families—as in the "266/T" regulations now in danger of annulment under the National Insurance Act. Dr. Brierley is to be congratulated on his contribution to our knowledge of the epidemiology of tuberculosis.

RADIOGRAPHY OF THE SMALL INTESTINE

Radiologic Examination of the Small Intestine. By Ross Golden, M.D. (Pp. 239; illustrated. 36s.) London: J. B. Lippincott Company.

The small intestine (other than the duodenum) has too often in the past been somewhat of a "blind" area to the radiologist, apart from such gross lesions as obstruction, tuberculosis, and regional enteritis. The time is therefore ripe for an authoritative

survey of the subject from the x-ray point of view. It is a pleasure to welcome Prof. Ross Golden's monograph and to pronounce it a work, from an authoritative pen, of first importance to radiologists and gastroenterologists.

The author's survey of the subject is very complete. He begins with a general introduction describing the indications for a small intestine study, and the technique both of the small intestine meal and the small intestine enema. Then follows an account of the embryology, anatomy, and physiology of the jejunum and ileum; and in discussing the physiology an account is given of the chemical mediator theory of nerve transmission and its application to the movements of the small gut. The author then describes the x-ray appearances in the normal small intestine, including the appearances in the infant—a subject that has received too little attention in the past.

In the section on obstructive and paralytic ileus there is a complete and informative account of the use of the Miller Abbott tube in diagnosis and treatment, which will be of great value to all who attempt this technique. One of the most important chapters is that on the x-ray picture of the intestine in disorders of nutrition: the physiological mechanism is discussed, and the nonspecificity of the changes wisely emphasized. Diseases of the mesentery, allergy, inflammation, neoplasms, congenital abnormalities, the effects of drugs, and miscellaneous conditions are described in later chapters, and the book ends with a bibliography of 200 references.

The print is readable, the book is free from padding, and the illustrations are well chosen and reproduced. It is a monograph to be recommended to all who are interested in this comparatively unexplored region. They will find in it much of interest and help in their work.

CLINICAL ELECTROCARDIOGRAPHY

Electrocardiography in Practice. By Ashton Graybiel, M.D., and Paul D. White, M.D. With the assistance of Louise Wheeler, A.M., and Conger Williams, M.D. Second edition, revised. (Pp. 458; 323 illustrations. 35s.) London: W. B. Saunders Company, 1946.

For the clinical exploration of the heart muscle the conventional limb lead electrocardiogram is no longer always sufficient. This fact is well demonstrated by Graybiel and White in the second revised edition of *Electrocardiography in Practice*. They show that, in general, an acute myocardial lesion may be inferred from the analysis of limb leads but that in some cases it will only be registered when the precordial leads are paired with one arm, the left foot, or the Wilson central terminal. The authors have given a readily understandable and fully illustrated account of this matter. While in this country the chest lead paired with the right arm is the technique in routine use, Graybiel and White consider that the Wilson central terminal will prove more satisfactory as it shows less potential variation than any single extremity. Errors of electrocardiographic interpretation are as likely to arise from lack of familiarity with the range of the normal as from failure to recognize an actual abnormality. This very real problem is excellently dealt with in Part II of the work. Later sections are devoted to the arrhythmias and the types and patterns of electrocardiograms in relation to aetiology. All the well-known aetiological groups are surveyed, and, in addition, the acute infections, nutritional and endocrine disorders, and the *cor pulmonale* to which the authors have made important clinical as well as cardiographic contributions. The presentation of a number of electrocardiograms for practice in interpretation will help readers to assess their own knowledge of the subject. Whatever is the result of this test there is no doubt that study of Graybiel and White's work will make many obscure points plain and fill some lacunae in the knowledge of almost every reader.

Notes on Books

Reconstruction by Way of the Soil, by G. T. WRENCH, is published at 12s. 6d. by Faber and Faber. In elaborating the title of his book, Dr. Wrench develops the thesis that farming is an art and something infinitely wider than scientific agriculture. It is a "Way of Life" itself. The family as a group is but a human complement of the soil itself, both family and soil recreating life. In the first three chapters he deals with the intensive personal agriculture which gave to the early Romans their physiological vigour and virile character. Although the carcass feeding of Polar Eskimos plays

almost the same prominent part as in beasts of prey, the lacto-vegetarian diet, wholemeal grain, fruits, vegetables, milk and its products are referred to as the food of many of the healthiest and strongest peoples of the present day. War and history depend much upon man's attitude to the soil. The author shows that although this attitude is ignored by historians it will give rise to a greater knowledge of the causes of devastating war and its prevention. Nomads and speculators who lead an ill-balanced life by not following the "rule of return" which is the only stable rule of living regard the soil as something to be exploited—even plundered—for their own gain, as a means to mastery and wealth. A more true valuation of the soil and its effects would be a powerful factor in the maintenance of peace. After dealing with the economics of soil, the proper and wrongful use of urban and rural waste, and the wonderfully successful methods of primitive farmers, Dr. Wrench has an interesting chapter on the effects of the dominance of money. The subject of this book is world wide: it calls for a means of action in reconstruction via the soil.

The Association of Special Libraries and Information Bureaux ("Aslib") has issued a *Catalogue of Films of General Scientific Interest in Great Britain* compiled by the Scientific Film Association. The classified subject index has five columns of entries under the general heading "Medical and Para-Medical Sciences," with a number of sub-headings. The catalogue can be obtained for 5s. 3d. post free from Aslib, 52, Bloomsbury Street, London, W.C.1.

General Bacteriology Laboratory Manual, by L. S. McCLEUNG of the University of Indiana, consists of instructions for 61 sessions of practical work in general bacteriology, with spaces for recording results. Though teachers of medical bacteriology rarely have time for dealing with the fundamentals of the subject in so extensive a way as this, they may nevertheless gain some useful ideas for the practical teaching of bacterial morphology and physiology. The publishers are W. B. Saunders Company, and the price is 6s. 6d.

Correction.—We regret that the name of the publishers of *Principles of Dynamic Psychiatry* by Jules H. Masserman was incorrectly given in our issue of Oct. 19 (p. 579). Messrs. W. B. Saunders Company Ltd. are the publishers of this book.

Preparations and Appliances

COMBINED HAEMOSTAT AND NEEDLE-HOLDER

Dr. J. S. LAURIE (Pontefract) writes:

Since the description (*B.M.J.*, Sept. 9, 1944) of my use of a hollow curved perineum needle for obstetric work, it appears that very widespread interest has been aroused in this simple little instrument. Messrs. C. F. Thackray, of Leeds, who made the original needle for me, have kindly designed a combined

haemostat and needle-holder in stainless steel, with grooves in the jaws permitting the needle to be gripped at either of two angles without damaging its lumen.

I have found this instrument very useful in giving more purchase and thus minimizing still more the discomfort to the tired mother, while the variation of angle covers most of the awkward positions in which one may have to work in domestic midwifery. It is of interest to note also that stitches with the round needle have much less tendency to cut out than those with a cutting needle as normally used.

The haemostat end saves duplication of instruments in an already crowded bag.

CONTROL OF LEPROSY

Up to thirty years ago the only method in common use for the control of leprosy in the British Empire and elsewhere was the Biblical and Middle Ages plan of compulsory segregation. For want of any effective treatment of the advanced cases, which alone filled the old type of leper asylums, that method nearly always meant lifelong imprisonment without hope of recovery. A prospect of an improved outlook was aroused when in 1916-17 Leonard Rogers reported better results in early cases treated as out-patients with injections of soluble preparations made from the ancient Indian remedy, chaulmoogra oil, in place of the oral administration of the nauseating whole oils. Early confirmation and extension of this work were furnished by E. Muir in India and by American workers in Hawaii and the Philippines, though it is of little value in advanced cases. Rogers therefore advocated large-scale clinic treatment of early cases, together with voluntary isolation of highly infective ones in agricultural colonies under expert treatment, which suffices to attract as many of them as can be accommodated. In India scores of thousands of out-patients are being treated every year at hundreds of dispensaries under trained experts; but funds are still lacking for the essential complementary colonies for advanced cases.

It soon became evident that compulsory isolation had become worse than useless, because it led the sufferers to hide their affliction for years until it had become too late for effective treatment. Rogers therefore made a comprehensive study of the literature of leprosy and formulated a plan of campaign to enable early cases to be discovered and treated and the more infective ones to be isolated with little or no compulsion—as described in a recent paper in our columns.¹ The essential points are that leprosy is mainly a house infection; that children are far more susceptible than adults; that the incubation or latent period after exposure to infection before the first symptoms appear is rarely over five years; and that neural cases—which constitute three-fourths to four-fifths of the sufferers in most countries—are little if at all infective, so these need not be isolated. It followed that close contacts of all discovered cases of leprosy should be examined at least every six months for five or more years to enable the great majority of new infections to be traced in a very early and, for the most part, recoverable stage. This plan has proved to be of value in the serious South Pacific Nauru epidemic; and in British Guiana and Ceylon, the

first British colonies to modify their compulsory laws to permit of its trial. Moreover, in South Africa bacteriological examinations of the 2,501 compulsorily isolated cases revealed that one-third of them were uninfected. Their release, together with the provision of agricultural colonies and improved treatment, soon resulted in most of the admissions being early voluntary cases. In twenty-five years 4,502 patients—two-thirds of the known total—had been released recovered, and three-fifths of them had remained free from active symptoms for five years and upwards.

In 1924 the British Empire Leprosy Relief Association (B.E.L.R.A. for short) was founded, with a daughter association in India. Working in close co-operation with the Colonial Office and Colonial Governments the successive secretaries, Mr. Oldrieve and Drs. Robert Cochrane and E. Muir, have made repeated tours through our Empire to organize the work. The most difficult problem was presented by Nigeria, with leprosy rates of from 1% to 10% and 70,000 cases in a single province. Here, through the combined efforts of the Government, B.E.L.R.A., and missionary societies, provision has been made of doctors, Toc H lay workers, and a trained indigenous staff; and agricultural colonies with numerous surrounding clinics have been organized. At two of these alone 25,000 patients are receiving regular treatment, with results that led the Nigerian Government to take over and extend the work with the help of liberal grants from the Colonial Development Fund. At the last annual meeting of B.E.L.R.A. Dr. Davey described the system of voluntary isolation of infective cases in model villages, built at the cost of the chiefs, together with village house-to-house surveys to find and treat the early cases at clinics—all with the essential cordial co-operation of the people. He is now able to report that in some areas the turning point has been reached and the incidence of leprosy is on the decline. At the same meeting the chairman of the Executive Committee, Sir Bernard Bourdillon, ex-Governor of Nigeria, announced that his memorandum clearly defining the respective roles of Colonial Governments and the Leprosy Association has been accepted by the Colonial Office.

The present position, then, is that the modern methods of control of leprosy have proved to be of value wherever they have been efficiently carried out, and machinery is available for their gradual extension to other affected areas. Progress must be slow in view of the fact that cases in the British Empire are estimated at about two million. In order to accelerate progress the most urgent need is the discovery of a more efficacious treatment of the more advanced and infective type of cases. Here, too, new hopes have been kindled by recent reports of more favourable results from the intravenous use of the sulphones, promin and diasone, respectively by Fite and Gemur² in the United States and by E. Muir³ in Trinidad. Further trials of these and other available preparations, which have already shown promise against the closely allied tubercle bacillus, should be carried out. Altogether the outlook for sufferers from leprosy has greatly improved during the last three decades.

PENICILLIN IN THE TREATMENT OF SINUSITIS

The value of chemotherapy in securing the rapid resolution of acute sinusitis must be accepted with caution. Cases in which inflammation does not extend beyond the mucous membrane generally get well with the usual conservative treatment, but progress is more rapid under treatment with penicillin—provided that the infecting organism is penicillin-sensitive—and in cases which prove resistant to ordinary treatment penicillin administered systemically is of great value. A more difficult problem is the conservative treatment of chronic, subacute, or acute on chronic sinusitis. Rüedi¹ has classified chronic sinusitis for this purpose as follows: (1) Simple infection of one sinus, usually the antrum; (2) a small group of cases of chronic pansinusitis combined with bronchiectasis; and (3) a large group of cases of "pansinusitis chronica polyposa" in which an allergic factor also is concerned. In general the treatment of chronic sinusitis with penicillin, whether by local instillation through ureteric catheters introduced into the antrum, or by systemic injection, or by a combination of the two, has proved disappointing, probably for three reasons: the penicillin does not affect organisms secluded in fibrous tissue and bone; there is often a component of the mixed chronic infections which is insensitive to penicillin (e.g., Friedländer's bacillus); and there may also be an allergic factor.

The experience of Bettington and Vincent² of military cases agrees with this. They found that acute sinusitis as such responded readily to chemotherapy with sulphamerazine, but that many of the acute cases seen were really acute reinfections, and some had already undergone operations for drainage of the antrum. Where drainage was good the cases responded well to treatment with sulphamerazine and lavage. For those without drainage openings sulphamerazine and lavage by puncture repeated four times was the routine; and if after this course had been repeated the result was not satisfactory penicillin was instilled through the cannula used for lavage. In spite of this they found that out of fifty-five patients with subacute or chronic sinusitis fifteen required radical operation; twenty-eight were cured by sulphamerazine, and ten by penicillin; and in two more operation was recommended but not performed. The fifteen who underwent radical operations all had nasal polyposis, which was regarded (as it was by Rüedi) as a condition particularly unfavourable for chemotherapy alone. Priest³ found that in chronic sinusitis, whether associated with bronchiectasis or not, treatment by penicillin was disappointing and that permanent improvement could seldom be obtained without operation, even though the penicillin was given systemically as well as by local instillation. Only two out of eight cases of chronic suppuration associated with bronchiectasis benefited from treatment with penicillin. Crowe,⁴ also, found that penicillin did not benefit chronic cases in which the infection had become inaccessible to local treatment.

The situation is different, however, in those severe and desperate cases where spreading osteomyelitis supervenes on chronic suppurative frontal sinusitis or pansinusitis, usually of the type associated with polyposis. In such cases, which previously responded only occasionally to drastic removal of bone, and then only if extradural and subdural abscesses had not already formed, the effect of systemic penicillin is dramatic. Rüedi has reported clinical details of ten such patients saved by the combination of operation with penicillin. The removal of bone need not be so extensive as was formerly practised, because of the great efficacy of the drug. Fortunately these cases are not very common, and no doubt more will be reported.

It was generally considered that in osteomyelitis arising spontaneously from chronic sinusitis the prognosis was less unfavourable than in post-operative osteomyelitis, which was almost always fatal after a prolonged illness. It now seems that more importance must be attached to the bacteriology. Bettington and Vincent found that the predominant and most constantly present organism in chronic sinusitis was a haemolytic *Staph. aureus*. Williams,⁵ however, has reported from the Mayo Clinic that in cases of osteomyelitis in which this organism is the infective agent there is a tendency for the osteomyelitis to localize, with a fair prospect of recovery after a radical removal of bone; but that when the organism is an anaerobic (or micro-aerophilic) short-chained streptococcus a malignant slowly spreading type of osteomyelitis is very likely to be fatal. Williams and Heilman⁶ showed that though this organism was fastidious as well as anaerobic it could be grown on dextrose-brain broth, and that an "autogenous antiviral" prepared from it was valuable in treatment. More recently, however, Hempstead⁷ has shown that this dangerous streptococcus is sensitive to penicillin, and the prognosis in osteomyelitis caused by it is therefore much improved. He refutes the view formerly held that *Staph. aureus* is responsible for the fatal form of infection. By the isolation of this type of streptococcus at the Mayo Clinic much that was mysterious in the course of the dreaded complication of sinusitis is explained; and the importance of bacteriological investigation is emphasized once more.

MATERNAL MORTALITY IN HOSPITAL PRACTICE

The last twenty years has seen a progressive rise in the number of women going into hospital for delivery. In England and Wales the number of institutional live births, which was 15% in 1927, had risen to 35% in 1937. This tendency is more noticeable in urban areas. In 1938 the number of births taking place in hospital or nursing home was 69% in the County of London, 49% in Liverpool, and 50% in Manchester. During the war there was a further steep rise and in some of the larger cities the percentage figure went up by as much as 15 or 20. In 1944 the Royal College of Obstetricians and Gynaecologists⁸ suggested that planning for the future should be based on the expectation that about 70% of all births will take place in hospital. If the facilities were available and properly distributed

⁸ Report on a National Maternity Service, 1944. Issued by the Royal College of Obstetricians and Gynaecologists. London.

roughout the country it would look as though this figure could be reached quickly. The trend away from domiciliary midwifery is even more evident in the U.S.A., where already in 1944 70% of confinements took place in hospital against 53% five years earlier.

With this in mind it remains to be asked how safe is institutional midwifery under modern conditions. All are agreed that where the nursing home or hospital and its aff are inefficient the risk to the patient is greater than she were delivered in her own home, but that where equipment and staff are adequate institutional midwifery is remarkably safe. The maternal death-rate in most of the large obstetrical teaching hospitals in this country is somewhat higher than that for the population as a whole and might be higher still if such hospitals regularly admitted cases of abortion, a condition which accounts for a considerable number of maternal deaths (0.4 per 1,000 total births in 1944). The figures as published, however, can be misleading. In many of these hospitals a large proportion of admissions are emergency cases, among which most of the deaths occur. The maternal death-rate of booked cases, even when these are selected principally for the reason that they are abnormal and likely to require operative delivery or other special treatment, is as a rule much better than that for the whole country—often two or three times as good. Moreover the hospital statistics usually include deaths from fortuitously associated conditions such as heart disease, whereas these are classified separately by the Registrar General.

The high degree of safety which now attaches to midwifery in a well-organized hospital is borne out by M. E. Davies and T. G. Gready,⁹ who have examined the records of all the maternal deaths which occurred in the practice of the Chicago Lying-in Hospital during a 13½-year period, 1931–45. There were eighty-one deaths among 47,945 patients, an over-all mortality of 0.17%. The maternal death-rate was over 4 per 1,000 live births in 1931 and gradually fell until it has been less than 1 per 1,000 since 1942, running parallel with and below that for the white population of the United States. The primary factors causing death were genital infection 23.5%, extra-genital infection (including pneumonia, phthisis, etc.) 16%, haemorrhage and shock 16%, heart disease 16%, toxæmia of pregnancy 7.4%, pulmonary embolism 7.4%, anaesthesia 3.8%, transfusion reactions 3.7%, and hyperemesis gravidarum 2.5%. The deaths due to genital infection all occurred before 1939, giving a subsequent five-year period free from fatal sepsis. Among 271 cases of placenta praevia there were only two deaths, and both are classified as avoidable. Two out of 237 patients suffering from abruptio placentae (accidental ante-partum haemorrhage) died. The incidence of post-partum haemorrhage, generally reckoned at 5–6% of all deliveries, was reduced to 1.1% during the years 1940–3. There were thirty cases of ruptured uterus, seven proving fatal. The frequency and risk of heart disease complicating pregnancy, which is now becoming one of the main causes of death, remained unchanged during the period under review. Delivery by Caesarean section was carried out 1,824 times, the lower-segment technique being employed in 1,704, the Porro operation in 98, and the classical incision in 22. The total mortality rate was 0.6%, but it was only 0.3% from the lower-segment operation.

Good as these results are, Davis and Gready conclude that two out of every three deaths could have been avoided. Preventable factors are charged either to the obstetrician, the institution, or the patient. They emphasize a fact which is not always appreciated—namely, that one of the chief

functions of a teaching institution such as the Chicago Lying-in Hospital is the training of young obstetricians: and no matter how well they may be supervised by the senior staff that always involves an increased hazard. The teaching of the future specialists is done at a cost; the greatest care is necessary if this is to be kept down to a minimum.

NEED FOR RESEARCH IN RHEUMATISM

The Empire Rheumatism Council has during the past week been celebrating its tenth birthday, and coincident with this is the announcement that the Nuffield Foundation has made a grant of £100,000 to be spread over 10 years for the establishment of a rheumatism centre in the Manchester Royal Infirmary. The importance of this step and the need for attracting research workers into rheumatism was referred to by speakers at the dinner of the Heberden Society held last week to welcome the official Swedish delegates—Prof. J. A. Höjer and Dr. B. Strandell. Dr. C. W. Buckley, who was in the chair, said that the Empire Rheumatism Council had its origin in earlier efforts to control the rheumatic diseases. The first was the appointment by the B.M.A. in 1931 of a committee on the causation and treatment of arthritis and allied conditions. Subsequently the Royal College of Physicians set up a committee and published the results of its work in four annual reports, the successor to which is the *Annals of the Rheumatic Diseases*, now published by the B.M.A. Then the Empire Rheumatism Council had been formed, and “almost side by side” the Heberden Society. Heberden with his nodes and Haygarth with his nodosities had been prominent figures in the history of rheumatism; and, Dr. Buckley added, Lord Horder, who had been so active in the campaign conducted by the Empire Rheumatism Council. Their problem, he said, was to educate the public and also the profession in the numerous problems of this disease.

Prof. L. S. P. Davidson developed the same theme, observing that during the past 20 years they had spent much time in trying to persuade central and local authorities of the importance of rheumatism from the standpoint of both economics and health. In 1937, for example, it was found that out of 2,000,000 incapacitated persons in Scotland 50,000 had suffered from rheumatism. Apart from small and private efforts he claimed that the matter had not yet been tackled at all. In the past the medical profession had been complacent about the problems presented by rheumatism. “We have run away from it.” But he was optimistic about the future. There were signs that general physicians who were not specialists in the subject were nevertheless becoming impressed by its great importance. If the efforts of Government Departments and the medical profession could be combined something, he thought, could be done to give the young man encouragement to undertake the research that was so badly needed. Dr. L. T. Swaim, of the U.S.A., and Dr. B. Strandell, of Sweden, both stressed that in their countries rheumatism also bulked large as a health problem, and a problem especially of general medicine.

Sir Wilson Jameson, speaking to the Empire Rheumatism Council on Monday, said the Ministry planned to have centres for research and diagnosis linked with university medical departments, “peripheral centres,” and beds for long-stay cases in institutions. The Ministry was going to make rheumatism one of the big problems to be tackled in the National Health Service. If it was to be properly studied in these centres they would need young people adequately trained as general physicians and also in the study of rheumatic diseases. He hoped they would come forward and take advantage of the opportunities available in the field of

⁹ *Amer. J. Obstet. Gynec.*, 1946, 51, 492

rheumatism. Sir Wilson ended by saying: "None of these official schemes for National Health Services and the like will thrive in the absence of first-class voluntary effort, and if the Empire Rheumatism Council will go on in the same way during the next 10 years no one will be better pleased than the Ministry of Health."

FIELD-MARSHAL MONTGOMERY ON MORALE

The subject of morale was chosen for the Lloyd Roberts Lecture delivered on Monday before the Royal Society of Medicine, Lord Montgomery said, for two reasons. The first was because high morale was a quality without which no war could be won; and the second: "I thought it would be of interest to the medical profession because morale is a mental quality, being essentially a product of the mind and conscience." He held strongly that the soldier was a citizen and not chiefly a military figure. As a citizen he would reflect the national character. "The national character is therefore of great importance, and anything that weakens it weakens the Army." In war the moral stature of some men would increase. Others, under the stress of battle, surrendered to fear and to fatigue and allowed their characters to disintegrate. "In such cases there has been a loosening of the character due to a partial surrender to fear." Lord Montgomery stressed that all through the question of morale there was the problem of dealing with fear. High morale was that quality which maintained human dignity at all times and developed man's latent heroism; it was not contentment, nor was it fitness or healthiness or happiness; nor was it toughness. "High morale implies essentially the ability to triumph over all difficulties, dangers, and discomforts, and to get on with the job." Lord Montgomery laid down four fundamental factors for morale: leadership, discipline, comradeship, and self-respect. He did not believe that devotion to a cause was basic or fundamental, although he subsequently observed that no nation could fight an unpopular war. Discussing leadership, he said that human beings had certain common characteristics and that in battle the most common of these was fear. All men were afraid at one time or another to a greater or less extent, and in fear men banded together and looked for guidance. "At such moments they are not capable of standing alone; they find the burdens too great to bear. The leader accepts the burdens of others and earns their gratitude thereby and the right to lead them." The quality men recognized in their leader was decision. Fear made a man sluggish and indecisive. The leader's power over his men was based on his ability "to cut through that fear paralysis" and so help others to escape from it. The leader's greatest asset was his ability to act normally in abnormal circumstances and to continue to think rationally when his men had ceased to think.

The object of discipline was the conquest of fear. The basis of fear was the awareness of danger. "A man becomes aware of danger when he thinks he is opposed by something more powerful than himself." Discipline helped a man to lose his own identity and created a corporate sense. Discipline also implied a conception of duty; but such conception, Lord Montgomery thought, did not embrace abstractions such as freedom, democracy, empire. A man's sense of duty extended to the friends round him. This brought the speaker to his third factor, comradeship: "Morale cannot be good unless men come to have affection for one another." Comradeship was the great antidote to fear because it gave a man friends. Self-respect, Lord Montgomery's fourth fundamental, was a quality which developed if the other three fundamentals were present. Men had to take pride in their ability to carry out any job. "A man who feels he is trusted will feel he is efficient and will begin to respect himself and have confidence in his

own ability." A powerful contributory factor to high morale was success; it was not possible to maintain it during a long period of defeat.

Returning to his theme that the soldier is first and foremost a citizen, Lord Montgomery said that nothing weakened a man more than trouble at home. The soldier had to have good living conditions and always good food, but there was a danger of considering welfare as an end. "It will never produce high morale by itself, because it is essentially soft." Hardness and privation, he said, were the school of the good soldier, and idleness and luxury his enemies. It was not for nothing that one of the great rallying calls of the English race had been the cry, "Blood, toil, tears, and sweat." Lord Montgomery ended a memorable lecture by referring to the strain on the leader whose men had a high state of morale: "They think that they can do no wrong, and they think that you can do no wrong; but it might stage a come-back on you."

D.D.T. FOR TROOPS

From statements in the press and on the radio and films it is well known that British troops in the recent war were protected from lice by shirts impregnated with D.D.T.—a procedure suitable for soldiers, whose uniform clothing can be treated *en masse* and issued as required. Such impregnated garments give longer and more reliable protection than the powder applied with a dusting gun, which was the rapid, simple treatment given to refugees and prisoners.

The biological testing necessary before this large-scale use could be instituted has been described by Musgrave recently.¹ (During the war the work was secret, and subsequently a considerable delay in publication was made inevitable by the spate of papers describing formerly secret research.) The biological assessment of effectiveness in killing lice was compared with independent chemical estimations of the percentages of D.D.T. remaining in undergarments after various periods of wear and numbers of launderings. A number of garments tested were distributed, as shown in the table.

Biological Assessment	Chemical Analysis: % D.D.T. wt./wt.				
	Less than 0.04	0.04-0.08	0.09-0.19	0.2-0.5	More than 0.5
Not effective ..	8	2	1	0	0
Slightly effective ..	2	2	1	0	0
Moderately effective ..	0	1	1	0	0
Effective ..	0	0	3	3	1
Very effective ..	0	0	0	1	2

The author concludes that 0.1% wt./wt. of D.D.T. on a garment is approximately the lowest limit for prevention of persistent lousiness. Garments originally impregnated with 1-2% fall to this level after four or five weeks' wear and four or five launderings.

Of interest is the time of contact required for the louse to receive a lethal dose. Lice were allowed to wander on impregnated clothing for various periods and then removed to a clean environment. It was found that all lice were killed some hours after one hour's contact with 1.75% impregnated fabric and that there was a high subsequent mortality among those which had crawled for three hours on fabric with as little as 0.1% D.D.T. Adult lice were observed to show clear signs of D.D.T. poisoning after four to six hours on 0.1% fabric and after two hours on 1.75% fabric at 30° C.

Sir Heneage Ogilvie will deliver the Bradshaw Lecture before the Royal College of Surgeons of England on Thursday, Nov. 14, at 5 p.m. Subject: "Surgical Handicraft."

¹ *Bull. entom. Res.*, 37, 43.

MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION

The first postwar meeting of the Council and of delegates of the Medical Women's International Association was held in London from Sept. 19 to 22 under the presidency of Miss Louisa Martindale, F.R.C.O.G. Representatives were present from Belgium, Denmark, Finland, France, Great Britain, Holland, India, New Zealand, Norway, Sweden, Switzerland, and the United States.

Women Doctors in the War

On the first day, the subject for discussion was the work of medical women in the Armed Forces and the Resistance Movement. Members were welcomed by Dame JANET CAMPBELL, president of the British Medical Women's Federation. She stressed the fact that medical women had a special contribution to make towards reconstruction and the establishment of peace and harmony in the world. She felt that an International Association of Medical Women supplied a valuable background and organization from which this work could develop. Miss LOUISA MARTINDALE pointed out that this meeting was being held in conditions of perfect freedom; that, for the first time or many years, everyone could speak openly and without fear. She hoped that members would maintain an international rather than a national outlook. She emphasized the serious effect of the war on the youth of all countries involved and felt that one of the most important functions of medical women would be to help in the redemption of youth.

Dr. S. LANOTTE (France), assistant physician to the Parisian hospitals, said that French medical women won an uncontested place in the Army during the later campaigns. The occupation of France made it impossible to set up an officially recruited force, and so it was entirely due to individual initiative that a body of women doctors got together and worked with the French Army in France, North Africa, Italy, England, Alsace, and Germany. The Women's Auxiliary Army Force, formed in North Africa in 1944, contained a Women's Medical Corps of over 150. This corps would persist, and had established for itself an honoured and privileged position in France.

Dr. LETITIA FAIRFIELD (one-time medical adviser to the A.T.S.) spoke of medical women's work with the R.A.M.C. They had complete equality of status and conditions with their male colleagues and worked in most of the theatres of war, not only in the care of the A.T.S., but in many cases in hospitals and casualty stations where the troops were treated. There were 600 women doctors in the Army before the end of the war.

Miss JOSCELYN MOORE (specialist in gynaecology lately employed in the R.A.M.C.) spoke of her work among wives and children of regular soldiers in 1940, and later with the A.T.S. The incidence of illegitimacy and of V.D. in the A.T.S. was remarkably low. The commonest disorders were associated with menstruation, though these were relatively mild. Dysmenorrhoea was worse in sedentary occupations and in a proportion of cases was an escape-phenomena, for the most part unconsciously produced.

Dr. DOROTHY FENWICK (former squadron leader, R.A.F. Bomber Command) said that women doctors were given important work in the Air Force and were well received by their male colleagues. One of their most interesting jobs was lecturing on personal hygiene and V.D. to all newly joined women in the W.A.A.F. She herself travelled 22,000 miles a year on visits of inspection. Every airwoman could consult a woman medical officer if she wished and a large proportion of them availed themselves of this opportunity.

Work for the Resistance Movement

Dr. FOG (Denmark) said that in the resistance movement in Denmark medical men and women worked together without discrimination. Medical women took an active part. They secretly received weapons, helped and transported saboteurs, hid refugees and parachutists, and acted as couriers. They were favourably placed for this work because the constant coming and going in their consulting-rooms made them a safe place of rendezvous. Their visits to patients afforded a means of conveying information, they had access to private telephone communications, and often used ambulances and hospitals to

save Jews and others whom the Germans were seeking. They were also able to use their cars to transport many people to safety during the blackout. Their medical and surgical skill was frequently employed in helping wounded saboteurs whom they kept in secret clinics and private houses. Many women doctors were discovered and sent to concentration camps for long periods. It was generally accepted in Denmark that they had done magnificent work.

Dr. DROEVER BONNET (Holland) stated that medical women played a similar part in her country. There was a strong resistance organization. One woman doctor was a leader of the whole movement, another who used her house as a centre of the resistance was arrested and killed by the Germans. Yet another became chief doctor in a German internment camp, as the German doctor left all the treatment to her. She was thus able to give great assistance to her fellow internees, and even to help some to escape.

Dr. ASTRID GULDBERG (Norway) told a similar story of medical women's work and heroism. Ten medical women were imprisoned for their share in the resistance activities, and one, who went voluntarily with her Jewish patients to Germany, had never been heard of again. The Norwegian women doctors felt proud that they were able to play such an active part in helping their people and their country.

Dr. DE BLAINVILLE (France) said that French women had also played a most active part in the resistance movement, and she herself was arrested for her resistance activities in 1944 and sent to Fresne prison near Paris, and then to Germany. There was no treatment or care given to the prisoners, and no medical services at all in the French concentration camp, and large numbers died. Transport into Germany was appalling; 125 people were put into cattle trucks, and many died on the way. She herself was sent to Ravensbrück, the biggest concentration camp for women in Germany; there were 16,000 there at one time without any medical attention. All property was taken from them, huts were densely overcrowded, and infection was rife. Examination for pregnancy was conducted with no attempt at cleanliness, and prostitutes were mingling with healthy women. Certain camp blocks were reserved for those to be sent to the gas chambers or the crematorium. Experiments were carried out on the prisoners with the greatest cruelty. The influence of the women doctors was mainly to try to comfort the women and raise their morale. This they did with great courage and devotion.

Dr. MICHOTTE-ROUSE (Belgium) spoke of her work in charge of a hospital at Bruges at the time of Dunkirk. A woman doctor had sole charge of the whole Malmédy region during the war and did outstanding work in Belgium. As in other countries, medical men and women gave the most devoted service at great personal risk.

Organization of Medical Care in Wartime

On the second day the subjects dealt with were Organization of Care and Medical Treatment during the war, and the problems of postwar reconstruction.

Dr. DOROTHY TAYLOR (senior medical officer for maternity and child welfare at the Ministry of Health) read a most interesting paper on the arrangements made by the Ministry for the care of mothers and children during the war. Dr. HEISE (Denmark) read a paper on the arrangements which had been made in Denmark. Miss LOUDEN (surgeon, South London Hospital) spoke of the work of the hospital during air raids. They dealt with men, women, and children. One patient had thirty fractures and yet made a good recovery. Dame LOUISE MCLROY spoke of the organization of maternity work in Buckinghamshire. Dr. HARDING gave an account of the life in the London underground tube shelters during the war, and of medical work among the shelterers. She stressed the excellent health that they had enjoyed despite the most unfavourable conditions, and also the high morale of both children and adults.

Dr. ESTHER LOVEJOY (U.S.A.), one of the founders of the Medical Women's International Association, said that the part of American medical women had been that of sympathetic observers, and that they had done what they could by sending money and such other things as they were allowed, both to the medical women of Britain and other countries.

Dr. BERGEROT (France) said that 600,000 arrests were made in France during the war, and there was still no news of

250,000 people who were deported to Germany. In one camp near Strasbourg over 45,000 people were used as subjects for vivisection, or experimental injection; 500 cases a day were used at Belsen for artificial insemination experiments. Among the deportees who were now returning, malnutrition was a great problem. It required a great deal of organization to try to sort out all these people and to re-establish them. There was an order in France that employers must take back their old employees, but this created great difficulties because so many of the returning men were suffering from emotional instability, loss of memory, and physical deterioration.

Dr. ANDREEN (Sweden) said that Sweden's role had been that of trying to help refugees from other nations. Thus 70,000 Finnish children were billeted in private homes and a great number were invalids or tuberculous. In 1944, 30,000 Baltic refugees were received, and in 1945 over 30,000 refugees and displaced persons came to Sweden. The large majority of the women doctors took an active part in this work. They had as far as possible kept up international contacts with other medical women colleagues during the war.

Problems of Relief and Reconstruction

Dr. MARCUS JEISLER (France) spoke about the psychological effects of the war on French children. She said that the peak figures of delinquency and emotional disorder in relation to children were reached in 1942, and had lessened since that date. The war definitely increased psychological disorders in children, but only in those who had already shown such tendencies. There had not been much increase in the numbers of children abandoned by their parents. There were a few cases of children living wild in groups or bands, who were found near the towns at the time of the wholesale deportations. A number were orphans, and were now in the care of charitable organizations. Some of the children who had lost their parents, or had seen them maltreated, wanted to avenge them. Some children were suffering from shock, and there had been a considerable increase of delinquency. Other countries had been very helpful. Switzerland had taken many of these children even during the war. Some had been sent to North Africa and some to Palestine. Sweden helped by sending money, and Great Britain in a number of ways. The question of the Jewish children had been particularly difficult. The surviving children of the deportees were like little savages. They had their own laws and their own chiefs and were brutal, but with patience they were gradually coming back to normal. The children were suffering greatly from lack of education during the war years, but German propaganda seemed to have affected them very little.

Dr. MIDDLEHOVEN (Holland) said that her country had set up an active system of relief units, which had enabled them to combat in a very short time the most cruel consequences of the hunger blockade of 1944-5, and to restore their normal hygienic and medical services. Many of their problems had been wounded soldiers, victims of air raids, and the rehabilitation of the many workers who had been deported by the Germans. Tuberculosis and syphilis had increased alarmingly among these people, and congenital syphilis among infants was not now uncommon. The Dutch population of the Netherlands East Indies, who were all evacuated to Holland after the capitulation of Japan, had lost everything and their physical condition was deplorable. In Holland, they were given material and financial help for six months, and as long after as necessary. Special dispensaries for tropical diseases and nutritional deficiencies had been set up. She was impressed by the marvellous training and education which the children had been given by their mothers in the Japanese camps. They behaved much better than the Dutch children, who practically ran wild during the war years. Those who had collaborated with the Germans presented another grave problem. They were still in camps, their children had been taken from them and placed in children's homes or with foster parents, as camp life was not suitable for them and it was feared that they would become infected with Nazi ideas.

Dr. HOLDERSON (Norway) stated that Norway had a population of only 3,000,000 though it was an extensive country. Their loss in personnel was heavy; 300,000 died in German concentration camps. There was also much material damage.

The medical women of Norway had played an active part in helping their people. America had sent them \$50,000 for relief work, and they were grateful for the help they had had from so many other countries. Dr. RUDINESCO (France) gave a further account of the efforts being made towards reconstruction.

Dr. CHAUSSE (Switzerland) discussed the part that her country had played in helping refugees of various nationalities, and said that though Swiss people had suffered considerable deprivations, and during the early part of the war had lived in great fear of invasion, they realized how fortunate they were to have escaped the horrors to which so many other countries had been subjected, and they felt it was a duty and a privilege to give as much aid as they could in the problems of reconstruction with which the world was faced.

At the Council meeting which took place subsequently, it was decided to hold the next International Congress and Council in Holland in June or July, 1947. The subject for discussion is "The Place of Medical Women in Postwar Reconstruction."

CENTENARY OF ACADEMIE DE CHIRURGIE

On Oct. 9 the Académie de Chirurgie of Paris celebrated its centenary, and invited the Royal College of Surgeons to send representatives. The Académie is, in fact, the successor of the Société de Chirurgie founded in 1843, itself the successor of the Académie Royale de Chirurgie founded by Louis XV in 1731. A party of ten attended the centenary celebrations and was representative of the Royal College of Surgeons of England, the Royal College of Surgeons of Edinburgh, and the Association of Surgeons of Great Britain and Ireland. On Sunday, Oct. 6, the party travelled to Paris and was met at the Gare du Nord by Prof. Louis Bazy and Prof. Leveuf, who escorted its members to the Hôtel Regina in the rue de Rivoli, where they were the guests of the French Government.

Celebrations in Paris

The centenary of the Académie de Chirurgie coincided with the 49th meeting of the Congrès Français de Chirurgie, which corresponds to the Association of Surgeons in this country, and on Monday afternoon there was the inaugural session of the congress in the great amphitheatre of the Faculty of Medicine. The President of the congress, Dr. Fourmestraux, of Chartres, reviewed the history of the congress in an eloquent address, and was followed by Prof. Roussy, Rector of the University of Paris, who spoke of the happy relations which exist between the University and the medical profession in France. The opening ceremony was followed by a discussion on pulmonary embolism, led by MM. Fontaine, of Strasbourg, and Redon, of Paris. In the evening the British representatives were entertained to a banquet by the French Government in the magnificent rooms of the Maison des Alliés, formerly the house of Henri Rothschild. M. Joxe, Director-General of Cultural Relations in the Ministry of Foreign Affairs, presided, and welcomed the guests in an eloquent oration. Sir Max Page replied for them in a most happy speech in perfect French. Two members of the delegation were presented with the honorary medal of the academy.

On Tuesday a discussion at the Faculté de Médecine on the conservation of the sphincters in operations for cancer of the rectum was opened by MM. de G. D'Allaines, of Paris, and de Vernejoul, of Marseilles. The material for the discussion had been most carefully prepared and covered an important field with thoroughness. New work was brought forward which is worthy of close consideration. In the evening the whole congress joined in a banquet at the Maison des Alliés. On Wednesday the discussion turned on the repair of peripheral nerves and was opened by MM. Wertheimer, of Lyons, and Merle Daubigne, of Paris. An important contribution was made by Prof. Seddon, of Oxford, and Miss Ruth Bowden. In the afternoon the British party were received at the Hôtel de Ville by the Municipal Council of Paris under the presidency of Prof. Basset, President of the Académie de Chirurgie, who reviewed at length the medical services of France and their possible developments in the future, dwelling more particularly on their relations with the Government. There followed the presentation of addresses of congratulation from the many

countries joining in the Congress. In the evening the visitors were invited as guests of the Government to the Opera, where they were delighted by a superb ballet which fully maintained the great traditions of the past. On Thursday a sword of honour was presented to Prof. Leriche on his admission as a member of the Institute of France. It was a happy ending to a great occasion, and a pleasure to all to witness the well-earned honour paid to one of the great leaders of modern surgery.

The members of the delegation were touched by the wonderful reception accorded to them by their surgical colleagues in Paris, by their generous hospitality, both public and private, and by the deep feeling of their friendship. It is hoped that the visit may have some small share in renewing the friendship between France and Great Britain which will surely have a most important bearing on a satisfactory solution of the present problems of European stability.

SCHOOL MEDICAL SERVICE IN SCOTLAND

The Scottish Health and Education Departments have recently issued a joint circular on the School Medical Service and the regulations proposed by the Secretary of State. The Medical Officer of Health will be appointed Chief Administrative School Medical Officer so that the best use may be made of clinics and of medical and nursing staffs, but since in the case of the larger authorities he cannot attend to the details of all the services for which he is administratively responsible, the regulations provide for the appointment of a Chief Executive School Medical Officer, who would have executive responsibility for the Service under the Chief Administrative School Medical Officer. The smaller authorities are permitted, with the approval of the Secretary of State, to appoint a Medical Officer of Health to both positions. A Chief Dental Officer will be appointed to develop the School Dental Service; and dental inspections will be carried out by dental officers instead of, as heretofore, by medical officers.

Medical supervision or treatment will be available under the scheme for pupils found at inspections to require either, and they may be referred to consultants if necessary. Officers will be carefully selected for this work, particularly for the difficult task of assessing mental disability.

Preventive medicine and the promotion of good health will be studied—an aspect sometimes neglected in the past owing to pressure of remedial work. The local authorities will encourage research, obtaining advice from the universities and other responsible bodies when required.

The Secretary of State may prescribe the intervals at which medical inspections of school-children shall take place. They will normally be conducted during the usual hours of attendance at school so that as little educational time as possible may be lost and the co-operation of the teachers gained. Parents will be invited to attend routine inspections.

NATIONAL CENTRE FOR RADIOACTIVE SUBSTANCES

It has been decided to establish a national centre for the processing and distribution of radium, radon, and artificial radioactive substances required for scientific, medical, and industrial purposes.

The centre will be a Government establishment, to be operated by Thorium, Ltd., acting as agents for the Ministry of Supply. As a first step the Ministry will purchase the radio-chemical business (including buildings and plant) owned by Thorium, Ltd., at Amersham, Bucks., with the exception of the manufacture of luminous compound and other secondary industrial products. The extraction of radon, which has, during the war, been carried on at Barton-in-the-Clay, Bedfordshire, under the auspices of the Medical Research Council, will also be transferred to the new centre. In addition Johnson Matthey and Co., Ltd., are voluntarily handing over to the new centre the whole of the business of filling radium into containers which they have conducted for many years.

Additions will have to be made at once to the Amersham premises to enable the centre to meet immediate demands. The Amersham site will not, however, be large enough permanently to accommodate the centre, as it is expected that the work, particularly on the artificial substances, will expand considerably. It is intended, therefore, to remove the centre to new premises when the shortage of building labour has eased and it becomes possible to form a clearer view of the volume and scale of the work. The work of the centre (which will be closely integrated with the activities of the Ministry of Supply in the field of atomic energy) will be controlled by a Council including representatives of the Ministry, of the managing agents and of users of its products.

PRIORITY SUPPLIES OF MILK TO INVALIDS

MINISTER'S APPEAL TO DOCTORS

The following announcement was issued by the Ministry of Food on Oct. 29.

The situation regarding the supply of liquid milk in this country during the coming winter will be even more difficult than has been the case in previous winters. The world shortage of cereals has influenced the supplies of feeding stuffs available for the dairy herds while the demand for milk in the United Kingdom has increased, partly as a result of the rising birth rate, partly from the demobilization of large numbers of Service personnel, and partly from a rapid increase in the number of persons receiving priority supplies on grounds of invalidism. At present the difficulties of the supply situation are such that it will only be possible to maintain the basic ration of 2 pints weekly to the normal consumer by economizing in the milk consumption of other categories. It is, therefore, necessary that there should be a review of the arrangements under which priority supplies are granted.

Through the period of hostilities the consumption of milk by invalids in receipt of priority allowances, although it showed a slight tendency to rise, remained about 900,000 gallons weekly. By December, 1945, it had risen to 1,200,000 gallons, and a further increase to 1,300,000 gallons weekly has occurred since. There is no other evidence that there was a 44% increase in invalidism and in default of this it must be concluded that medical certification for milk priorities has become less strict.

The average consumption of milk by each invalid is 12 pints weekly, that is, 10 pints more than the normal consumer when the basic ration is 2 pints a week. A reduction in medical certification for milk priorities to the level pertaining in 1944 would save 330,000 gallons of milk weekly, an amount which, together with other savings which will be effected, would probably suffice to prevent the allowance to the normal consumer falling below 2 pints weekly.

Three Possibilities

The Minister of Food has consulted with the Food Rationing (Special Diets) Advisory Committee* of the Medical Research Council as to the measures required to effect the necessary economies. There are three possibilities. (1) The allowance of milk to individual invalids in the different categories can be curtailed. (2) The number of categories can be reduced. (3) The present categories and present allowances can be maintained but an appeal to the medical profession can be made to observe scrupulous accuracy in certification as to confine the issue of certificates to patients in the category sanctioned. This committee advised against the first measure because they believed that reduction in the present allowance of milk to invalids would render therapy difficult. They advised against the second because they considered that the present schedule of illnesses qualifying for priority claims cannot be curtailed without excluding patients to whom milk is a therapeutic necessity. They favoured the third measure because the committee had confidence that, when the medical profession had been informed of the present situation of the country's milk supplies, they would endeavour to effect the necessary economies. The Minister has accepted the committee's advice but it will be appreciated that the need for economy that if the measure proposed fails then one or other measures the committee deprecates might have to be implemented.

Realizing the difficulty of adopting stricter methods of certification when doubtful cases are in receipt of certificates, the Minister of Food has decided that after Nov. 30, 1946, no medical certificate for priority milk (whether for milk alone or for milk and other food) dated before Nov. 3, 1946, shall be valid. It is hoped that practitioners will take the opportunity for re-certification provided to explain to applicants for such certificates that the measure proposed is imperative to apply stricter criteria.

* The Food Rationing (Special Diets) Advisory Committee following membership: Sir Edward Mellanby (Ch.), L. S. P. Davidson, Sir Francis Fraser, Lord Hord Lawrence, Prof. R. A. McCance, Dr. M. L. Rosenheim, Prof. J. C. Spence, Prof. H. P. Himsworth (

PROTEIN METABOLISM IN RELATION TO DISEASE

The presidential address in the Section of Experimental Medicine and Therapeutics of the Royal Society of Medicine was given on Oct. 8 by Prof. H. P. HINSWORTH (University College Hospital).

It was a commonplace, said Prof. Hinsworth, that although there were only twenty-two amino-acids for the construction of all varieties of protein, no two proteins were alike. There were subtle differences between the proteins of the same organs derived from different animals. In part the tissue differences could be related to differences in the amino-acid composition, as also could one species difference, that between human and cow's milk, but most species differences were far too subtle to be detected by chemical analysis and called for immunological tests. It was possible with the development of more delicate methods of chemical analysis that species and perhaps tissue differences would be found dependent on attached substances rather than on amino-acid composition. But each protein was characteristic and remained true to type. By altering the amount of dietary proteins the amount of protein might be altered, but not apparently the composition of tissue proteins. Imperfect and unusual proteins never seemed to be produced by the body. This had led to the assumption that the protein in the tissues was a stable structure rather than something on the same plane of metabolism as carbohydrate or fat, yet it appeared that the proteins of the body, far from being stable structures, were in a state of rapid change. Individual amino-acids were continually being broken down and the fragments built into different or similar amino-acids. It seemed as if the whole protein structure of the body at any one time were boiling with activity, yet the tissues retained their characteristic structure, and a dynamic equilibrium must exist to maintain stability of protein composition. This new view, astounding as it was, threw light on the puzzling question of labile body protein. When a starving animal was fed it retained considerable quantities of protein, but on starving it again the protein was broken down to an extent roughly equal to the amount stored. Under the old view of endogenous and exogenous protein, such protein could not be stored, and nobody had been able to demonstrate stores of protein in the body. It was true that certain cells, such as those of the liver, enlarged on repletion and shrank on starvation, but the chemical composition of the cells in respect of protein appeared to remain constant. According to the new view the ingested protein was incorporated into the mass of living protoplasm within the body, which at any particular time was adjusted to the protein intake; with decrease of intake the tissues broke down.

Protein Requirements of the Body

In considering the requirements of the body for protein a distinction must be drawn between the requirements for a particular protein when that constituted the sole source of an amino-acid, and the requirements for a mixture of protein such as occurred in normal diet. Ordinarily this was an academic question, only likely to arise in experiment or perhaps when illness had grossly limited the intake of food, in which case the amino-acid composition of the protein became of importance; but in health the protein requirements were largely independent of such considerations, the differences in the amino-acid composition of the different proteins which made up the normal diet mutually compensating for each other's deficiencies. If protein was the sole source of food it had to only to contribute to the building up and maintenance of tissue but also to serve as fuel. On the other hand, if the diet contained other adequate sources of energy then protein could be turned to its proper use, and of sources of energy in the diet carbohydrate was the best protein sparer. Such conditions apart, the special problem of general protein requirements in health came down to a determination of the extra requirements for growth, pregnancy, and lactation. In Western civilization normal adults required about 1 g. protein per kg. body weight, children up to 3 g., with women in pregnancy and lactation at intermediate figures. What was the justification for the liberal

allowances of protein for the normal adult when many races subsisted on much smaller allowances? It was not a question of absolute inadequacy but of optimal and sub-optimal nutrition. Recent studies of starvation in Europe had shown that when protein intake was greatly reduced it was quite possible to establish lactation, and the milk was normal in composition, but lactation could not be maintained for more than two or three weeks. Reports from the East suggested that races on low protein diet, when injury or infection was incurred, developed complications which were not present, or present only in mild form, in races on a high protein diet. Gross restriction of protein was required to produce illness, but a mild restriction was sufficient to cause illness under strain, the common strains being growth, pregnancy and lactation, infections, injury, and surgical operations.

Biologically speaking, the requirements for amino-acids fell into two groups: those which had to be supplied in the diet and those which had not. These were classed as essential and non-essential amino-acids. By means of tracer elements it had been shown that the body was capable of synthesizing all the amino-acids with the possible exception of lysine, but apparently the rate of production of ten amino-acids was too slow for the needs of the body and these had to be supplemented by the diet. Thus they had come to be regarded as essential, but the remainder must not be considered as optional substances, and any one of the dozen non-essential amino-acids might in the future come to be upgraded as essential. It was not even certain that all the ten were always essential. Their reputation had been based on animal experiments concerning growth. There was some evidence that in man under certain conditions these ten amino-acids would form proteins more effectively on injection than when whole protein was given by mouth, but that had yet to be confirmed. Analyses were available of the amounts of these amino-acids in diets which were normally considered adequate, but it was evident that the requirements varied, both quantitatively and qualitatively, at various stages of development. Closely bound up with the question of essential amino-acids was the conception of the key amino-acid. If an essential amino-acid were removed from the diet the body began to break down protein rapidly and continued to do so until the amino-acid was restored. It appeared that definite proportions of certain amino-acids were required for the construction of any protein; if one was missing that protein could not be constructed and the excess of amino-acid was burnt off and appeared in the urine as nitrogen. The missing amino-acid thus became a limiting factor, a key component in protein synthesis.

Protein Deficiency

It was a truism that a deficiency state arose when the demand for nutriment exceeded its supply. Protein deficiency could be produced either by curtailing the supply of protein to the body or by increasing the utilization of protein by, or loss of protein from, the body. Supplies might be restricted because of inadequate diet or conditions in the alimentary tract; increased utilization might be the result of pregnancy, fever, metabolic diseases such as diabetes mellitus, injury, or operation; excessive loss might occur because of leakage through the kidney or exudates occurring in conditions such as burns. Dietary deficiency did not ordinarily occur in Western civilization. Starling's dictum still held good: "Take care of the calories and the proteins will take care of themselves." Whatever the calorie value of the diet, 10% to 12% of the calories was taken in the form of protein. But there were Eastern races living on diets grossly deficient in protein. There, deficiency states referable to protein deficiency occurred. The development of clinical states due to dietary deficiency seemed to be dependent on the ability of the body to store the particular foodstuffs. Energy foodstuffs could be stored in quantity, but protein and most vitamins only to a limited extent. In famine, therefore, protein deficiency dominated the picture, but in normal conditions it was usually secondary to some illness, which might be a structural lesion of the alimentary tract, a surgical operation on the tract, or anorexia, limiting food intake.

Practically nothing was known as yet about specific amino-acid deficiency in man. It would be difficult for this to occur as a result of direct dietary deficiency although it might be secondary to other illness. Certain poisons combined with

nino-acids and produced pictures which experimentally could be imitated by amino-acid deficiency. Possibly some complications developing in conditions of great protein loss, as in burns, might be related to deficiencies of certain amino-acids. Plasma proteins appeared to be formed, at least in part, by the liver. Plasma albumin and two of the globulins were certainly formed here; the source of the remaining globulins was not settled. Of the plasma proteins the albumin was most susceptible to abnormal conditions. In starvation its blood level fell relatively rapidly. If dietary intake of protein was adequate, and protein as lost from the body or there was failure to synthesize sufficient albumin, the plasma globulin steadily rose, so that the total plasma protein value might reach normal or above normal levels. The reason for this was not clear, but at least it tended to restore the reduced osmotic tension of the blood. Perhaps the most striking objective manifestation of plasma protein deficiency was oedema. Evidently oedema was most closely correlated with albumin. It was possible that when dehydration was present oedema might not be able to form, and it was a common experience that when starving patients with dysentery were brought in they had no oedema but rapidly developed it as soon as fluid was administered. But it had to be remembered that in starvation there were other deficiencies; probably also an increased capillary permeability played a part in oedemas occurring in famine.

Conditions Causing Excessive Protein Utilization

Among the conditions which produced excessive utilization of protein were fever and injury. In febrile illness there was an excessive breakdown of body protein, shown by increased nitrogen excretion and raised basal metabolic rate. Neither the fever nor the increased metabolism themselves caused this excessive breakdown. It had been loosely termed toxic destruction, but the same phenomenon occurred after a simple injury where there was no question of an extrinsic toxin's gaining access to the body. The process seemed to be a reaction of the body itself to trauma. From 12 to 24 hours after a simple fracture the nitrogen excretion in the urine would begin to rise, presently reach a maximum, then slowly return to normal, and during convalescence reach sub-normal levels. Immediately after the injury, therefore, there was an excessive breakdown of body protein, followed by a phase in which the body was taking up more protein than it was breaking down, and at the end of convalescence protein intake equated output. In the stage of active breakdown it was possible to mitigate but hardly to prevent the excessive excretion of nitrogen by increasing the dietary protein, but as the breakdown diminished it became correspondingly easy to promote nitrogen retention.

Nitrogen breakdown was augmented by immobilizing the patient. Several suggestions had been made as to the significance of this phenomenon. That it was by no means negligible was shown by the calculation that in the first ten days after a simple fracture nitrogen corresponding to more than 8% of the total body protein might be excreted—i.e., more than four times the amount of protein contained in the liver. Clearly if all that protein destruction had occurred at the site of the injury it could not have escaped detection, but the body structure as a whole seemed to be involved. It had been suggested that this was to provide the large amounts of amino-acids required for the healing of the injury, and implicit in that suggestion was the idea that certain key amino-acids were required for healing, that these were produced by breaking down of body protein, and that the other amino-acids not required by the tissues were rapidly burnt off and accounted for the increased nitrogen excretion. There was still doubt as to the mechanism of the phenomenon. The practical lesson was, before operation, to remedy any protein deficiency. In acute illness protein intake must be maintained at a reasonable level, but there was no point in pushing it to excess. As soon as the illness began to improve protein should be pushed, because apparently this shortened the period of negative nitrogen balance. Those who had followed high protein regimes during convalescence were impressed by the increased well-being of the patients. He touched on protein metabolism in relation to liver injury; it seemed clear that protein deficiency could lead to liver necrosis. Necrosis produced by lack of cystine was what was called acute yellow atrophy and in survivors went on to a fibrotic condition of the liver.

In concluding his brief survey, which was delivered to an overflowing audience, Prof. Himsworth said that many subjects of clinical interest had been omitted—the effect of protein depletion on the development of immune bodies, the toxic action of excessive doses of amino-acids when given in association with low protein diets, the therapeutic use of protein hydrolysates or mixtures of pure amino-acids—but he hoped he had said sufficient to show that the problems of protein metabolism in relation to disease were now under intensive study and to indicate some progress which had certainly been made.

FOOD POLICY

A conference of the Nutrition Society on "The Work and Aims of the Food and Agriculture Organization" was held on Sept. 21 at the London School of Hygiene and Tropical Medicine. Sir JOSEPH BARCROFT presided.

Mr. D. LUBBOCK, speaking on "Nutritional Aspects of the World Food Picture," outlined the history of F.A.O. since its inception in October, 1945. The first objects had been to raise the level of nutrition of the peoples of the world, to improve the production and distribution of food, and to secure better living conditions for those engaged in the production of food. These demanded a long-term policy, and the first activity of the organization was to seek the guidance of nutrition experts and various official bodies in the collection of data on the amounts of food consumed in various countries before the war. A "yard-stick" would thus be made available for measuring the after-effects of the war, and for assessing future progress towards better standards of nutrition. Early in 1946, however, reports from U.N.R.R.A. and other bodies responsible for finding food for the war-stricken areas indicated that, in addition to the usual chronic deficiency of food in certain areas, the world was about to experience an acute temporary shortage of supplies. In May a special meeting of F.A.O. was held in Washington, and the situation was greatly eased by persuading the wheat-producing countries to increase their exports, and by discouraging the extravagant use of wheat for feeding to animals or for milling into flour of an unduly low extraction rate.

It was realized that the urgent shortage was not merely a 90-days crisis, as had been expected, but that in the spring of 1947 the situation might be even worse. International co-operation was obviously necessary to avoid the farmers' fear of surplus production with consequent collapse in prices, which tended to limit the output of the agricultural community. In view of the urgency of this problem the annual conference of F.A.O. was held two months earlier than had been scheduled, and in September delegates from many nations met at Copenhagen to discuss proposals for the formation of a World Food Board.

Need for Expanding Economy

The choice of policy for food production lay between two alternatives. We might, as before the war, have a static economy, in which production would be limited by the power of populations to purchase food. Future prosperity, however, must depend on an expanding economy, in which production would aim at improving the nourishment of both rich and poor nations throughout the world, with the solution of financial difficulties by international agreement. The amount of surplus which under present conditions would cause a disastrous slump in prices was in reality only a small fraction of the food urgently required by the undernourished populations. A preparatory commission was therefore considering a plan, to be ready before the end of this year, which would have as its main points: (1) the assurance to the farmer of steady world prices for his commodities; (2) the accumulation of world reserves of wheat and other commodities to tide over future periods of emergency; (3) the provision of funds for financing the disposal of surplus agricultural products on special terms to countries where the need for them was most urgent; and (4) the development of food production in backward countries where there was at present severe undernourishment.

It would obviously be impracticable, except in the far distant future, to bring all nations to the same standards of nutrition. Most nations had well-established "food patterns," based on inherited custom and religion, which must be respected in

planning dietary reforms. A survey of national food supplies, covering 70 countries and 90% of the world's population, had indicated that very wide differences existed. Thus the average food intake in Korea was 1,900 calories daily, but 3,300 calories in New Zealand. Moreover, while large amounts of milk were consumed in some countries, such as Britain and America, negligible amounts were available in other countries, such as China. Every country must therefore have its own target for immediate improvement. The consumption of one pint per head of fresh milk might be a reasonable aim in Britain, but the most that could be expected for China was the introduction of a minute "token" amount of milk into the diet, probably mostly in the dried form.

While therefore F.A.O. saw its most urgent task in raising the levels of nutrition in backward regions, it was obvious that in many countries salvation must be sought in increased agricultural efficiency rather than in surplus food produced in other countries. Such increased efficiency must be encouraged by expert advice supplemented by material help, and F.A.O. proposed that missions including an agriculturist, a nutritionist, and an economist should be sent to countries requiring their services. Experience had already shown that when the food supplies of any nation fell below a certain level there was a tendency for organized government to break down. The principles advocated by F.A.O. to secure better nutrition and increased prosperity throughout the world might be our only hope for the prevention of war.

Nutrition Programme of F.A.O.

Dr. W. R. AYKROYD said that the Organization had among its aims: (1) the collection and dissemination of expert information on nutrition, food production, and agriculture; (2) the co-ordination of national and international action; and (3) the promotion of research, education, and the spread of public knowledge on these subjects. A standing committee including eleven members from various nations, with Lord Horder as chairman, had been set up to give advice on nutritional problems. It must be made clear, however, that F.A.O. could not finance research, that it had at present no executive power, and that its staff was necessarily small because of the very limited supply of experts available for service. To obtain results, therefore, it must rely upon its powers of persuasion and the willing collaboration of other interested individuals and organizations.

The various forms of action which F.A.O. could take might be aptly illustrated by considering the problem of school meals. In the first place the organization might pass a high-sounding resolution—e.g., "The nations here represented agree that a satisfactory diet is the birthright of every child, and recommend that immediate steps should be taken to ensure that this problem receives due attention on the part of the educational authorities." In the absence of concrete suggestions and more direct stimulation, however, it was unlikely that much effective action would be taken by the authorities concerned. A second plan might be to summon a committee of nutrition workers to discuss the problem, but few experts were so widely travelled as to be familiar with food supplies and habits in all the countries of the world. Perhaps the most effective action, therefore, would be to make arrangements for investigations into the feeding of school-children to be carried out in different countries, with attention focused on definite points, such as the details of organization, the food supplied, the costs, and the effect on the children's health.

The secretariat of F.A.O. had great responsibility in formulating problems and in preparing material for conferences in a form that would ensure their success. The recent world food survey had shown that much secretarial work was necessary in comparing estimates from different sources, and that great disparities might arise from alternative methods of calculating nutrient values and in the use of different food tables and conversion factors.

Among the special interests of F.A.O. were the milling and processing of cereals, food technology, and the effects which wartime food programmes had had on the public health in various countries. Another activity was the compilation of a list of the world's nutrition workers, which should be of use when it was necessary to recruit volunteers for special F.A.O. missions. Although the organization would draw largely on

the help and interest of other bodies, however, it would not merely act as a "post-box" but would have its own team of technical experts. Since the newly formed World Health Organization was also to have a nutrition division its activities ought to be correlated with those of F.A.O., and a joint committee of the two bodies would deal with such subjects as deficiency diseases, standards of nutrition, and the control of the quality and purity of foods, which were of common interest. Under present conditions the people of some fortunate countries were well nourished on food produced by a small proportion of their population. In others the toil of almost the entire population was insufficient to yield an adequate amount of food.

Need for Processed Milk

Miss E. FAUTZ discussed this special problem. Since F.A.O. had recommended that the world's milk supply should be doubled, it was important to explore the implications of this policy, particularly in countries where all available food was now required for direct consumption by human beings, and could not be spared for dairy cows. In such countries much benefit might be derived from the importation of processed milk, particularly dried skimmed milk. The demand for milk products might well be stimulated by propaganda and by suggestions for their incorporation in manufactured foods, while their purchase in necessitous countries might be facilitated by financial loans or by grants during the next three years from the U.N.R.R.A. Children's Fund. An increase of milk products would improve nutrition in the West Indies.

Sir JOSEPH BARCROFT among other speakers, in an informal discussion, spoke highly of the nutritive value of various forms of dried milk. In his opinion F.A.O. was not sufficiently well known to the general public. More public interest might be aroused if the Organization had executive rather than exploratory powers. The Government was fully pledged to implement its decisions, which would then have immediate and direct effects on our weekly food rations. It could not be denied, however, that some "economic smoothing out" was essential, and he hoped that F.A.O. would soon be able to report progress on the reactions of Soviet Russia to its policy. The Nutrition Society should be told of ways in which it might help the work of F.A.O.

CAUSES AND PREVENTION OF PREMATUREITY

A meeting of the Paddington Division of the B.M.A. was held at the County Hall (L.C.C.) on Sept. 24, with Dr. G. DE SWIET in the chair, for a discussion on "Prematurity: Causes and Prevention." The CHAIRMAN said that in Paddington twelve or thirteen years ago the infant mortality was the highest in London; the spectre still haunted them, and unless constant efforts were made there was always the danger of a return to that position. Prematurity accounted for about one-fourth of infant mortality, for about half the neonatal deaths, and half the stillbirths. Its prevention was a problem of major importance. Mr. R. LOVELL (pathologist to the Royal Veterinary College) discussed certain veterinary aspects. In the dairy industry the mortality of calves resembled infant mortality in the respect that the reduction had obtained at the older ages, while the hard core—nearly half the calf infantile mortality being in first week—in the very young remained.

Obstetric Indications

Prof. F. J. BROWNE (University College Hospital) said that the League of Nations Committee in 1937 recommended that any infant weighing 2,500 g. (5½ lb.) or less should be considered premature irrespective of the duration of gestation. About 5% to 8% of all births were premature, and prematurity accounted for 50% of the 20,000 neonatal deaths. Stillbirths were about ten times as frequent in premature as in full-time deliveries. Study of the case sheets of 100 premature births, in University College Hospital, showed no cause in 53; in 14 there was multiple pregnancy, and in 13 toxæmia. Any serious attempt to reduce the number of premature births must begin with an attack on the high incidence of prematurity from unknown causes. Consideration should be given to social conditions and especially to deficient diet. In the group in which the prematurity was associated with an abnormality in mother or child, little was possible, in the present state of knowledge, in

event of the premature births. A great deal could be done making more antenatal beds available. The admission of patients with ante-partum haemorrhage to hospital as soon as the first warning occurred would result in a great diminution of the premature and stillbirth rate. The early diagnosis of aemia and institutional care would enable many cases to go to term when otherwise intrauterine death and premature labour would result. Instrumental termination of pregnancy should be possible, in those cases in which it was necessary, be delayed until the end of the 37th week as it would make all the difference in the chances of survival.

Eugenic Considerations

Prof. L. S. PENROSE (University College) said that prematurity and mental retardation were correlated and that transcranial cerebral haemorrhage might be the cause. Paediatric authorities were convinced that cerebral diplegia was mainly due to intracranial birth trauma. Observations

Queen Charlotte's (Martin, 1931) showed that the duration of pregnancy averaged 278.3 days (with a standard deviation of 16.4 days) but ranged from 195 to 360 days. There were more than twice as many premature as postmature babies. Some common specific causes of prematurity might be postulated. One of these causes was the occurrence of multiple births; twin pregnancies terminated, on the average, 15 days, and triplet pregnancies 24 days, earlier than the normal. Factors in the paternal sperm were considered as causes of premature delivery. Icterus neonatorum was, in most cases, due to the fact that the foetal blood contained an antigen, received from the father, which the mother did not naturally possess and to which she formed antibodies. Antigenic incompatibility of fetus and mother was undoubtedly a cause of infant mortality, and miscarriages and premature births were part of its picture.

Dr. LETITIA FAIRFIELD said that the fundamental gap in their knowledge concerned the factor which set up the process of expelling the child from the uterus after an average period of nine months. There were so many unknown influences in gestation that its duration was largely in the region of guesswork and not of scientific ascertainment. Dr. C. L. WILLIAMS said it was important that during the later months of pregnancy the woman should do nothing involving physical strain, especially the use of the hands above her head, as it was by attention to small things like that that the 50% neonatal deaths due to prematurity would be reduced. Dr. DE SWIET, in closing the discussion, suggested that the role of the male parent might have to be more emphasized. It might be necessary to deal with the "expectant father" and to enter the realm of preconceptional care, and Prof. BROWNE commented: "A valuable discussion, and it shows that we do not know anything at all about the subject!"

As announced last week, an extraordinary meeting of the members of the Liverpool Medical Institution was held on Saturday, Oct. 19, with the President, Dr. G. F. Rawdon Smith, in the chair. Addressing a large gathering of members, the President stated that the meeting had been called for the purpose of conferring Honorary Membership of the Institution on six eminent members of the medical profession, Dr. Alfred Ernest Barclay, Sir William Allen Daley, Dame Anne Louise McIlroy, Prof. Charles McNeil, Dr. Ivan Whiteside Jagill, and Sir Alfred Webb-Johnson. Dr. Robert Coope acted as orator for the occasion, and introduced the new Honorary Members severally. They were then formally admitted by the President, and each made a brief reply, expressing appreciation and thanks to the members. In the evening, the Honorary Members, together with the Lord Mayor of Liverpool and other official guests, were entertained to dinner at the Exchange Hotel.

The Hunterian Society's programme for the session 1946-7 includes discussion at Apothecaries' Hall on Nov. 18 at 8.30 p.m., "That the vertisement of proprietary medicines is a menace to the public." Dec. 16, at a dinner meeting at 7.15 p.m. at Pimm's, 3, Poultry, "Dr. Geoffrey Evans will open a discussion on "Flatulence." Jan. 20 Prof. Debaiseux, of Louvain, will give the Hunterian Lecture on "Hypotension in Intracranial Injuries" at the Mansion House at 8.30 p.m. On Feb. 24 Mr. V. Zachary Cope will give the Erian Oration on "Literature and Doctors" at the Mansion House at 8.30 p.m. On March 17, at a dinner meeting at Pimm's at 7 p.m., Sir Reginald Watson-Jones and Dr. J. B. Menzell will open discussion on "Sprains and Strains."

Correspondence

Selection of Medical Students

SIR,—Prof. D. H. Smyth's admirable general discussion of problems of selection in the case of medical students, and your comments upon his article (Sept. 14, pp. 357 and 375), make it exceedingly clear that the time has come when these problems must be taken seriously. It is very likely that some agreed methods ought to be put into practical operation without delay, but it is quite certain that the really urgent need is for a well-planned and large-scale investigation in which as many as possible of the medical teaching schools and hospitals would co-operate and in which medical men and psychologists would join, each side with a genuine willingness to understand and appreciate the perhaps somewhat different points of view that are involved.

Prof. Smyth rightly points out that a large amount of valuable experience in regard to selection methods and problems has been accumulated during the war. A brief but definite statement of the main practical conclusions that are generally agreed seems now to be desirable, and it is such a statement that I will endeavour to make.

1. No system of initial selection is likely to get beyond the stage of debate unless its results can be systematically and accurately checked against independently determined proficiency criteria. If possible, obviously such criteria should be capable of objective determination, but some progress has been made towards the establishment of a reasonably reliable technique based upon informed assessment, and there is certainly far more hope that such a plan may be satisfactorily established in suitable cases than could have been predicted six or seven years ago.

2. As things are there is almost no operation, trade, or profession having any major importance in civil life for which adequate proficiency criteria have been established. Prof. Smyth's remarks show that no such criteria are agreed upon in the case of medicine, and that if suitability for the practice of medicine "as a whole" is taken as the aim the chance of ever establishing such criteria in a practical sense is small. His own conclusion seems to be the only possible one—i.e., that a few qualities which offer a reasonable chance of being amenable to test and validation procedure should be picked out and made the basis of the more routine or formal aspects of selection. This does not, of course, ignore the other aspects of selection, but war experience has shown many times over that it lightens and often improves the work of those responsible for their consideration. Perhaps Prof. Smyth goes farther than is necessary when he seems to imply that routine selection should be limited to dealing with intelligence only; but this is a matter for discussion.

3. It is quite clear that the primary function of intelligence tests in relation to the professions is at present that of exclusion. As regards some vocations it has become clear that they will tolerate a range of intelligence above as well as below which prospective candidates are little likely to achieve success. He would be a rash man who would assert that there is an upper limit of tolerance in the case of medicine, but everybody agrees that there must be a lower limit, and though this has not yet been settled it ought to be not difficult to determine it by a well-planned investigation, and meanwhile a rough working limit could be achieved and used. It is essential that such a limit should be used intelligently and in conjunction with the less formalized aspects of selection, because for validation purposes it is obviously necessary that a sufficient number of cases should be available for "follow up" who do not in fact make the proposed grade for formal selection.

4. Every important war investigation has shown that it is impossible to separate selection from training. A good selection scheme can be ruined by a bad system of training. A bad selection scheme can, within limits, be bolstered up by a good system of training. It has turned out with truly astonishing monotony that training schemes can be as completely divorced from subsequent operational success as a plan of initial selection can be. Indeed several times over it has been found that initial selection methods which do not agree with training grades do agree far better with eventual operational success. The importance of this, which can scarcely be exaggerated, is that where good operational criteria are lacking there is an inevitable tendency to judge selection methods by the relation of their results to training grades. This may be extremely misleading and unfair.

So serious did problems of this order become, for example, that towards the end of the war a number of investigation teams in the U.S.A. who had been concerned with primary selection were forced to turn their attention wholly to training methods and training

assessments and examinations. Some astonishing facts came to light. Training methods and courses are very often indeed a hodge-podge of different devices. There may have been a good reason for every one of them when it was introduced, but they have come in at all sorts of different times and for all sorts of different reasons and purposes. Training schemes are far more often overloaded than under-loaded, and it is very common to find candidates kept for a long time learning things that the general run of them can perfectly well master in a short time, and for a short time on things which require more prolonged study. The result is staleness in some directions, under-training in others, and that most curious state of affairs in which it is accepted that a candidate's training must almost begin all over again when he goes from the school to his eventual career. In this country the only case I know of a thoroughly validated selection procedure from first to last was one in which selection and training were treated as a single problem. I can see no hope at all for a really successful issue to primary selection in the case of medicine unless medical authorities are prepared to submit existing training methods to a radical investigation and to take a very open-minded part in such investigation themselves.

5. It has become clear that follow-up technique and testing technique are not the same and in a serious investigation should almost certainly be the concerns of different groups. In general the more any type of investigation requires field study the more important it is that a leading part should be taken by people with interests, knowledge, and skill relevant to the field concerned. Whereas the kind of testing which is now under discussion is very largely a technical psychological problem, the follow-up is mainly a matter which is best directed by medical personnel. Fortunately there are now an increasing number of the latter who have also a satisfactory training in normal and experimental psychology. It is this kind of training which is required. Doubtless there are also psychiatric problems involved in the initial selection of medical students, but on the whole, though there is no complete agreement, the weight of recent experience is heavily against mixing up the psychiatric with the normal problems of selection.

6. Tests of intelligence in a general sense, as distinguished from those which have to do with highly specialized skills whether mental or bodily, must employ a variety of principles and a variety of media. The media commonly used are words, numbers, and visual—usually geometrical—forms. All three are required. The principles must include both structural and relational factors, and these have to be treated both analytically and constructively or synthetically. No set of tests which are merely repetitions of the same pattern of problem presented in varying complexity can be regarded as satisfactory.

7. There is impressive evidence, not as yet given much publicity, that the type of intelligence which deals efficiently with the symbols of words, numbers, and visual forms has no necessary relation to another type which deals directly with complex situations in terms of the immediate data of those situations. It seems highly probable that the latter type of intelligence may be very important for certain aspects of the practice of medicine, especially in regard to clinical skill. Any long-term investigation of the value of intelligence tests in initial medical selection should give due regard to this.

These are, I think, the main principles that have emerged from the work of the last few years. There are in addition a great many details which need attention and trial. It is not improbable that several of the conventions which, for very good reasons, are usually observed in the design and presentation of intelligence tests may undergo change. Some of these, for example, are the arrangement of test items in a regularly increasing order of difficulty, the use of one-way questions and answers only, and current practices about time and speed setting. These and other matters, including some of the statistical measures commonly demanded, should not be taken as settled.

Smyth is certainly incautious in one respect, that coaching and practice make no difference to the results runs a long way beyond established facts. But he does yet know for certain what exactly are the implications which the undoubted results of training and practice may have for intelligence test scores.

The practical conclusion seems to me to be this: the time is ripe for setting up a small but influential body of medical doctors and of psychologists with the necessary resources to implement any decisions they may make after discussion. This body should aim at a long-term policy of investigation and also at a short-term policy for immediate, but provisional, application. The latter ought not to be at all impossible provided the probable ratio of candidates to places in those medical schools which would take part in it is known.—I am, etc.,

The Psychological Laboratory, Cambridge.

F. C. BARTLETT.

Classification of Psychological Disorders

SIR,—Instead of criticizing each other on the problems nomenclature would it not be better if we frankly admit that it is not possible to pigeon-hole every patient neatly under some simple diagnostic label? This is not the fault of psychiatrists but is due to the complexity of human nature, which exhibits infinite variations. The unique individuality cannot be stretched so as to align accurately upon one of a limited number of Procrustean patterns. By all means let us test students the distinguishing features of "typical reactions" depressive, hysteric, anxiety, and so forth—but let us also insist that in a considerable number of cases we have to deal with "mixed reactions," because personalities are mixtures of many artificially separated types.

With the neurotic it is far more important to obtain a complete record of his biographical development than to label a small cross-section of his life. A psychiatrist who is able to say, for example, that the patient is reacting to frustration of occupational ambitions and a state of marital disharmony in accordance with certain behaviour patterns conditioned by various childhood and adolescent experiences is being more practical, and will be able to do something far more useful for his sufferer, than any pundit who is happy only when he can exhibit a clear-cut diagnosis. It is unfortunate, therefore, that some of our over-enthusiastic E.C.T. exponents seem to consider it more important to attach hastily a diagnostic label to their patients than to make a painstaking study of their histories; hence the statistical fallacies concerning which I Dillon very rightly issues a timely warning (Oct. 19, p. 58)—I am, etc.,

Basingstoke.

Goitre without Bias

SIR,—Few there are, I think, who would deny that surgery as performed by an expert is the method of choice in the treatment of thyrotoxicosis. Nevertheless there are some features which call for discussion. In the first place I am sure that the average doctor would require a lot of convincing if he were told that all the mild adolescent colloid goitres seen should be submitted to surgery. He would look back across the years and ask himself how many of these goitres have really become toxic, and how few indeed have become malignant. In support of this idea Garlock¹ states that about 2% of thyroid enlargements are malignant, and he informs that Smith, Pool, and Olcott² emphasize that it may be the undue weight is being attached to the probability of cancer developing in an adenoma. He remarks trenchantly:

"As one reviews the statistics of three or four decades ago when goitre operations were unusual and patients harboured adenomata did not accept surgical intervention as freely as to-day one is impressed by the fact that few cancers of the thyroid were noted, far fewer than would be expected did adenomata present the marked tendency towards malignancy which is generally assumed to-day."

Turning back the pages, we find that in Allbutt and Rolleston's *System of Medicine* it is stated that 50% of patients recovered completely on rest and sedatives, while Osler³ informs us that "Statistics are misleading, as only the severe cases come under hospital treatment. Probably 65% of the patients make a good recovery, and 10% to 12% die." It is well perhaps to remind ourselves that a majority of patients did recover by various methods of treatment, while admitting that the results did not compare with good modern surgery.

With regard to thiouracil, and the new methyl and propyl derivatives which are much less toxic than the former, it is surely too early to condemn them out of hand. It is true to say that many patients have shown complete remissions, which have lasted so far under the administration of these compounds combined with rest in bed for a few weeks at the outset. Admittedly it does require a lot of experience to determine which patients may be suitable for medical measures, and also all when to advise operation so as to give the surgeon a fair chance. Much could be said did space permit on the question

¹ Nelson's *Lower Leaf System of Medicine*.

² Smith, L. W., Pool, E. H., and Olcott, C. T., "Malignant Disease of Thyroid Gland: a Clinicopathological Analysis of 54 Cases of Thyroid Malignancy," *Amer. J. Cancer*, 1934.

³ *Text Book of Medicine*, Osler and McCrae.

of diagnosis, but the all important thing is to bear the condition in mind, especially where there is undue nervousness with restlessness, unexplained wasting, or diarrhoea, or the presence in mid-life of tachycardia or an abnormal rhythm. The difference in the response to iodine and methyl-thiouracil on the one hand and sedatives on the other may be strikingly suggestive; and lastly in the few as yet undetermined cases we should remember Osler's dictum, "Diagnosis in the borderline cases depends more on careful study and observation than on any single test."—*I am, etc.,*

FREDERICK SUTTON.

Carbon Dioxide Absorption

SIR,—Mr. A. Charles King (Oct. 12, p. 536) gives an interesting historical survey of anaesthetic apparatus, in the course of which he states: "In 1932 the first apparatus proper in this country was made for Frankis Evans, and this was followed by alternatives designed by Shipway, Harris, Halton, Primrose, Gillies, and others."

On reading this, I referred to my own records on this matter and find that I have a patent specification applied for in Oct. 16, 1931, No. 391,176, covering circuit breathing combined with an inflatable pharyngeal tube. A further patent specification, No. 419,679, dealing with to-and-fro breathing was applied for on June 30, 1933. Messrs. Barr and Stroud made my third machine, which was ordered from them on April 8 and delivered on May 20, 1932. The fifth machine of my series, home-made, was described at a meeting of the Anaesthetic Section of the Royal Society of Medicine, I think in the spring of 1934, while a subsequent machine was that used at the Annual Meeting of the British Medical Association held at Bournemouth in 1934.

I offer these facts as supplementing what Mr. King has given from his records, and should it turn out on investigation that a prior claim has been established through these facts, then the Glasgow Royal Infirmary must be regarded as the home of carbon dioxide absorption technique as at present practised.—*I am, etc.,*

Glasgow Royal Infirmary.

W. B. PRIMROSE.

Recent Advances in Anaesthesia

SIR,—In Dr. Langton Hewer's most interesting article (Oct. 12, p. 531), I note that he dates recent advances as those occurring between 1914–18 and the present time. He is thus able to do full justice to the advances in premedication, to the new volatile anaesthetics, to technique and apparatus, and even to the most recent adjunct to anaesthesia, curare. It is therefore all the more surprising that no reference whatever is made to intravenous anaesthesia, which has almost supplanted the older methods in certain types of operation—for this great advance was made within the period specified.

Jarman and Abel (*Lancet*, 1933, 2, 18) appear to have been the first in this country to describe the use of evipan; Dickson Wright (*Lancet*, 1935, 1, 1,040) drew attention to his apparatus for giving intravenous anaesthesia; and finally Jarman and Abel (*Lancet*, 1936, 1, 422 and 600) give an account of the action of pentothal sodium in over one thousand cases. I feel that to complete your account of recent advances in anaesthesia these facts should be added.—*I am, etc.,*

London, W.1.

J. JOHNSTON ABRAHAM.

John Snow—Anaesthetist and Epidemiologist

SIR,—In praise of Snow's perspicacity your contributor (Oct. 12, p. 535) writes, "Where Snow was in advance even of Farr and Simon was in his firm conviction that the ingestion of water polluted with a presumably living contagium was the only method of epidemic dissemination." I fear that the emphasis given by the italics may tend to deprive Snow of credit for that other remarkable and original, but less well known, inductive inference relating to the epidemiology of cholera which H. Harold Scott in *Some Notable Epidemics* records as follows:

Yet another shrewd observation of Dr. Snow. A friend told that, having placed in his room in summer when flies were abundant an infusion of quassia to kill them, he could often taste bitter quassia on his bread-and-butter. If then flies could convey

quassia from a saucer to food they could as readily transfer fragments of cholera dejecta present on linen. He cited this as another possible mode of contracting infection."

—*I am, etc.,*

London, S.W.5.

IAN E. MCCracken.

SIR,—“It may not be generally realized how profound were many of Snow's views” writes Mr. Charles King (Oct. 12, p. 536), and the otherwise excellent *Anaesthesia* Number of the *Journal* does little to remedy this. In the column written on John Snow, only half a paragraph refers to his work in anaesthesia. Of the pioneers, none contributed so much, in observation or theory—the first to record the sign of intercostal paralysis and the first to postulate interference with oxygenation as the cause of narcotic action; in practice—the expiratory valve, wide-bore tubing, warmed ether bath, and “safety” chloroform inhaler; and in experimental work—forty-two pharmacological animal experiments, using, besides ether and chloroform, ethylene, amylene, refrigeration, and even endotracheal intubation. Again quoting Mr. King: “The idea of the carbon dioxide technique had entered the fertile brain of John Snow.” Yet he died in 1858, only twelve years after Morton's demonstration.

By reprinting *Snow on Cholera* America has made sure that his fame as an epidemiologist will live. In this centenary year, could not a British house be persuaded to republish the all too rarely seen *On Chloroform and Other Anaesthetics*?—*I am, etc.,*

London, S.W.16.

JOHN IVES.

Penicillin Injections and the Boiling of Syringes

SIR,—One is alarmed at the letter by Dr. P. Finch (Oct. 19, p. 589) who, because he is informed that ethyl alcohol does not inactivate penicillin, states that he is employing industrial spirit for syringe sterilization as boiling wastes a lot of time. One of the lessons that should have been learnt from World War II is that syringes cannot be sterilized adequately by fluid disinfectants and that when such methods are used syringe-transmitted hepatitis becomes rife, especially when intravenous injections are being employed. By early 1944 the jaundice rate in syphilis patients attending Service venereal disease clinics had reached a very high percentage and was only controlled when the boiling of syringes was made compulsory. The incidence of syringe-transmitted jaundice is much lower after intramuscular injections, but cases following penicillin therapy are far from unknown and will become more frequent if the precaution of boiling is in any way relaxed.—*I am, etc.,*

A.M.D. 10, War Office, S.W.1.

R. R. WILLCON.

Potency of Penicillin

SIR,—Penicillin has now become a commonplace and is used by thousands of doctors. It is admittedly the greatest advance in treatment of many bacterial infections that formerly were regarded as almost hopeless, and in lesser degrees of infection markedly shortens the period of recovery and convalescence. But there is one snag. There is no test that the ordinary practitioner can use to determine whether any given sample of penicillin has or has not lost its potency. We are told that under certain conditions of temperature watery solutions will remain active for 3–4 days and that oily solutions will last a week. But this is not definite enough and I am convinced that much inactive penicillin is being both injected and inhaled, thus often causing great disappointment. I hope some simple test of efficacy will soon be discovered and described.—*I am, etc.,*

London, S.W.1.

DESMOND MACMANUS.

Transmesenteric Hernia

SIR,—Dr. R. B. Leech's letter (Sept. 7, p. 339) on the subject of mesenteric hernia adds yet another example to the ever-increasing list of reported cases. With the cases of Peter Martin (*British Medical Journal*, 1946, 1, 238) and James Moroney (*Ibid.*, 329), the views I expressed on the aetiology (*Brit. J. Surg.*, 1944, 31, 275) are confirmed in that all three patients showed a defect of the mesentery near the caecum,

with smooth and regular margins, and apparently without the surrounding vessels' showing evidence of previous thrombosis or injury. This is the "Treves's field," as described by him in 1885 (*British Medical Journal*, 1885, 1, 470). Mr. Martin states that trauma and inflammation are aetiological factors, but this is very much a minority view, the general opinion being that the hole results from a developmental fault, and that intestinal movements ultimately, though not inevitably, cause a knuckle of bowel to pass through and initiate the obstruction.

Neither Mr. Martin, Mr. Moroney, nor Mr. Leech mentions any relevant previous history of abdominal injury or disease in any of their patients, which again supports the view of a congenital origin. I am quite sure that trauma sufficient to cause a breach in such a thin yet strong membrane would have to be (a) localized and crushing, and (b) of considerable force, with inevitable severe injury to surrounding tissues—such as bowel rupture and vascular damage. Again, I can conceive of no tearing injury applied to the mesentery which, if sufficient to cause a localized tear, would not also result in widespread mesenteric rupture with accompanying haemorrhage. Inflammation could only cause such a defect by localized adherence of some inflamed organ to the mesentery, followed by sufficiently violent peristaltic movements or trauma to tear the viscus off either with a small attached portion of mesentery or leaving behind a slit. Again, this has to occur without vascular damage, and has to leave a smooth margined defect with no thickening or irregularity of its edges, and without surrounding adhesions or bands, to concur with the conditions found at operation in all these cases.

Careful consideration therefore of trauma or inflammation in a causatory role leads us to reject both as quite impossible, and I submit that all such mesenteric defects are congenital in origin. I feel that this opinion is confirmed by the occasional finding of such defects without other related pathology in post-mortem examinations of persons dying from other causes—e.g., Watson's 3 cases in 1,600 necropsies. May I point out to Mr. Martin that his case is not the 49th on record but at least the 78th.—I am, etc.,

Woking.

E. G. DOLTON.

"Cord Round the Neck"

SIR.—The recent correspondence on this controversial topic justifies a report of yet another case of stillbirth attributable, presumably, to "cord round the neck."

I was called in by a midwife because of delay in the second stage of labour. The patient was a primipara, 27 years of age. Antenatal supervision had been adequate and periodic B.P. and urine tests revealed no abnormality. There was however some oedema of both ankles during the later weeks of her pregnancy, but the patient was otherwise in excellent health. There was no obvious pelvic disproportion, and the presentation was a vertex. She went into labour on the calculated date of delivery. When I saw her she had been nearly five hours in second stage. She was having good pains and strong contractions every five minutes, but once the head reached the perineum its subsequent progress was slow. Time after time a good contraction caused the *caput* to appear, only to disappear tantalizingly on the cessation of the pain. It seemed as if something was hindering the downward progress of the head, and when the neck was palpated a single loop of feebly pulsating cord was found tightly wound round it and incapable of being slipped off. A finger was insinuated with difficulty between the neck and the cord and the latter immediately divided between ligatures. The child was delivered shortly afterwards. The foetal heart rate just prior to delivery was 120 per minute. Despite the adoption of the usual methods of resuscitation, the child never took a breath, though the heart continued to beat for at least 30 mins., 100 per minute at first and then gradually less. There was no mark of constriction round the neck, and the face and body were pale. There was no congenital malformation of the upper respiratory passages. The cause of death was presumably pressure on the cord and consequent asphyxiation of the child before delivery. The cord was of average length, and the placenta and membranes normal and complete. There was no perineal tear.

It is unjustifiable on the basis of a single case to attempt to lay down hard and fast rules regarding the early recognition of this anomaly, but three suspicious signs may be of value, namely: (1) Undue delay in the second stage of labour in an apparently straightforward case. (2) A diminishing foetal heart rate. (3) The appearance and disappearance of the *caput* with but little downward progress when the head is well down on

the perineum. The early recognition of "cord round neck" and the application of forceps might conceivably the child, but one feels that, for the occasional obstetrician at any rate, once the diagnosis is made it is probably too late to do anything except sever the cord and deliver the child speedily as possible, with or without instrumental assistance.—I am, etc.,

Glasgow.

Smallpox in the Vaccinated

SIR,—In regard to smallpox in the vaccinated, Dr. F. Beaumont's (Sept. 21, p. 437) and Dr. C. Killick Millard (Oct. 12, p. 552) comments seem to me most helpful and so the latter proposes annual revaccination for those in repeated contact with smallpox cases. May I support this out of experience of eight years with Europeans in India?

In a population of some 500 Europeans living in an Indian industrial town, where smallpox was as everyday and as common as a sore throat, it was our practice annually to revaccinate the whole population at risk. There was no case of smallpox in these people, not even modified smallpox, but the war brought imperfectly protected vaccinated persons to England among us these unfortunates were in grave danger and there were some appallingly bad clinical cases of smallpox. One such case, of confluent smallpox, was vaccinated in infancy (scar not visible) and had a certificate of three negative results from vaccination done before leaving England.

It is of course not practicable to vaccinate and revaccinate the whole population of Britain annually, but I suspect to follow the modified course of doing it every five years would end the worries of the public health people about introduced epidemics.—I am, etc.,

Edinburgh.

J. ROSS INNES

SIR,—It is refreshing to find Dr. Killick Millard advocate more frequent vaccination. In the early days of the ceremony he was claimed by the Anti-Vaccination Society as their supporter in the medical world, although I remember hearing him at that time open a meeting against compulsory vaccination with the words: "I want you first of all to agree vaccination does protect against smallpox."

We public vaccinators did not receive much encouragement from the Local Government Board. If we revaccinated a person within ten years of the last revaccination we could charge a fee for it. We were instructed to obtain four vesicles in revaccination. I refused to do more than three and put forward the suggestion that infant vaccination should be done in stages—the first the "minimum-of-trauma" method, to be followed a year later by a more "vigorous" vaccination. This suggestion was turned down, partly, I suspect, because of double fee.

I endorse Dr. Killick Millard's recommendation "little often": recent vaccination protects not only against smallpox but against a sore arm. To the question that was frequently asked, "Is it necessary for me to be vaccinated again now?" my answer was, "I can only answer that question by vaccinating you."—I am, etc.,

Leavesden.

H. ANGELL LANE

Legal and Medical "Insanity"

SIR,—The letters and article are of importance in trying to assess correctly where one condition passes into the other, the correct treatment in each case. The diagnosis of "psychopathic personality" is now so frequently, lightly, and dangerously made by young psychiatrists that it could easily be applied in some way or other to a large proportion of the nation, including not a few psychiatrists. Once thus labelled a psychiatric patient is at the mercy of any malicious or ignorant person who may wish to exploit the patient or any particular situation to his own advantage. Thus the patient's condition gets worse and will continue to get worse under the present system, where cause and effect are so often confused.

A nervous breakdown may be due to intrinsic or extrinsic causes. In the cases which are due to extrinsic causes, we must be very careful to distinguish between those extrinsic causes which the patient is unfortunately exposed through no fault

s own, and those which are deliberately brought in to play against him by interested parties. The importance and numbers of this particular type of case are not sufficiently appreciated. This type the people who are the causal factors in the events which specifically cause the breakdown of some unfortunate person are far more dangerous than any so-called "psycho-athic personality," and treatment or other measures should be directed towards them rather than towards the patient. Undoubtedly, psychiatrists accomplish a tremendous amount of good in their psycho-analysis of the nervous breakdown due to ordinary extrinsic causes; but, in the type of case I wish to emphasize, the best thing that the patient can do is to keep far away as possible from a psychiatrist and disentangle himself from a procession of psychiatric platitudes, otherwise he will never get better.

Most doctors, whether they be specialists or general practitioners, know when they have made a mistake. But what check, at all, except in particular cases, is there on the mistakes of young psychiatrists, and are they even conscious of the mistakes they make? That is why sometimes a man may get a truer verdict, and in the final analysis better treatment for himself, by the consensus of opinion of twelve impartial members of a jury, who have all the material facts before them, including the medical evidence. The case of Heath as quoted in your correspondents' letters is obviously a very far-fetched one, but the mind of the ordinary person the verdict cannot but have been received as logically just.—I am, etc.,

London, N.W.11.

A. LIONEL ROWSON.

Recruits for Medical Missionary Work

SIR,—We wish to ask publicity for the presentation of an appeal to young doctors, men and women, to consider medical missionary work as a career. We feel convinced that a large proportion of those now entering the medical professions are not aware of the vast opportunities offered by the work sponsored by the Christian Churches over-seas. The thrill of adventure has perhaps worn a little thin in medicine as practised in this country, but such is not the case in a mission hospital in Africa, China, or India. There the medical man of resource and initiative will find an opportunity for his every latent ability. The call of untouched suffering is still as strident as when it stimulated his predecessor 75 years ago; the wealth of clinical material is still as exuberant. But the medical missionary to-day is not called upon to work in a dark lean-to against the mission bungalow, with no trained assistants and tragically restricted equipment; he is not forced to leave half his cases undiagnosed for want of a microscope, nor to lament the inevitable sepsis following each surgical procedure.

The medical missionary of to-day has a wide choice of types of practice into which he may put his life. There is much pioneer work to be done in the front line of the attack on disease, where a high degree of initiative and much improvisation will be demanded in the rough-and-tumble of professional activity. On the other hand, he may be asked to work in an institution which structurally can compare with hospitals at home; he will be assisted by nurses trained as carefully, and with hands as skilful, as those staffing English hospitals; to operate in a theatre where aseptic ritual is understood and practised, with available those drugs and most of the equipment which would be found in, say, one of the smaller provincial hospitals in his own country. Moreover he will almost certainly be asked to co-operate in the teaching of nationals—either nurses, technicians, or, in certain picked institutions, internes; he will find his work naturally integrating with local government schemes.

To the medical worker who has the vision to show through his profession his evangelical faith, who would speak to men and women, through the medium of the healing art, his Master's words of Eternal Life, there is open to-day a door of unbelievable opportunity. Writing on behalf of the Medical Advisory Board of the Conference of British Missionary Societies, we would be delighted to supply further information to any doctors wishing to consider this realm of work.—

Medical Experiences in Japanese Captivity

SIR,—One effect of the authoritative and restrained contribution of Lieut.-Col. E. E. Dunlop (Oct. 5, p. 481) will almost undoubtedly be the production of still more and more hate for a nation whose people could sink to such atrocities. It is because I fear for a world where hate seems to be flourishing so luxuriously that I am driven to mention a relatively small experience. I too was a medical officer in a Japanese internment camp, where 615 British civilians were imprisoned from March, 1942, until August, 1945. We suffered no brutality; we were forced to no labour except that of feeding and running the camp. The Japanese authorities supplied the camp hospital with a not inconsiderable portion of its equipment, and facilitated our acquisition of that major portion which came from the Shanghai British Residents' Association, the International Red Cross, and the American Red Cross. The Japanese personnel frequently "requested" drugs and treatment, and even if this was often unreasonable, the news that the commandant had "requested enough sleeping pills for three nights" was NEWS of the best order to the camp, as his insomnia was invariably and correctly regarded as being due to the reception of bad news from Tokyo.

The normal reaction to such a document as that of Lieut.-Col. Dunlop is one of horror, followed by a mental indictment of the whole nation. Nothing is to be gained from refusing to see and admit the large areas of depravity represented by the records of Japanese treatment of prisoners. Yet even if the less sordid pictures are presented in the press less frequently, it is surely as well that they too should be recorded, still good to "think on these things," rather than occupy memory exclusively with horror.—I am, etc.,

London, N.W.1.

RALPH BOLTON.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a Congregation held on Oct. 19 the following medical degrees were conferred:

M.D.—E. Hinden, W. B. D. Maile, H. L. Ellis.
M.B., B.Ch.—E. L. McDonald, M. G. Cox, *M. Q. Birbeck, *E. A. D. Boyd, *R. Finlayson, *B. O. Reed, *P. F. C. Jackson, *J. H. Jacobs, *I. M. Ramsden.
M.B.—J. L. Morgan.

* By proxy.

The Vice-Chancellor announces that Eli Lilly and Company have undertaken to provide £3,500 for a period of one year for research on the relation of radiation to chemotherapy. The research will be carried on in the Department of Radiotherapeutics under the direction of Dr. E. Friedman.

UNIVERSITY OF LONDON

Regulations for the Postgraduate Diploma in Psychological Medicine, revised to September of this year, are obtainable from the Director of the Department of Extra-Mural Studies, University of London, Imperial Institute Road, South Kensington, S.W.7. The examination is held twice a year: Part A in March and October; Part B in April and November. It is open to any candidate whose name is in the *Medical Register*, or who is registrable therein, provided that before being admitted to Part B the candidate produces evidence that he has had the clinical experience and made the attendances specified in the Regulations.

The following candidates have been approved at the examinations indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN CLINICAL PATHOLOGY.—G. C. T. Burns, V. V. Gharpure, J. Gluckman, S. W. A. Kuper, R. Polakow, R. Serpou.
EXTERNAL DIPLOMA IN CLINICAL PATHOLOGY.—E. M. Barker, W. G. Davis, J. B. Eulacknap, P. N. Meenan, W. P. Stamm.

St. George's Hospital Medical School

Clinical demonstrations in oenurology and psychiatry will be given in the Medical School on Thursdays, at 4.30 p.m., by Dr. Anthony Feiling and Dr. Desmond Curran, and are open without fee to all practitioners and senior students of medicine. The first lecture of the renewed series will be given by Dr. Feiling on Dec. 5.

Arrangements made by the Ministry of Supply will ensure that at present any oil-wax suspension of penicillin produced will conform with the formulae of the *British Pharmacopoeia*, or with some other formulae previously approved by the Ministry of Health. These other formulae will include preparations using ethyl oleate.

Obituary

T. WARDROP GRIFFITH, C.M.G., LL.D.,
M.D., D.Sc., F.R.C.P.

We regret to announce that Dr. T. Wardrop Griffith, emeritus professor of medicine in the University of Leeds, died at his home in Stainbeck Lane on Oct. 21. He had been for many years a leading figure in the medical world of Leeds and the West Riding of Yorkshire.

Thomas Wardrop Griffith, eighth son and last surviving child of Charles Fox Griffith, J.P., of Aberdeen, was born in that city in 1861; he was educated at Aberdeen Grammar School and University, graduating M.B., C.M. with highest honours in 1882, and then held a demonstratorship of anatomy. He came south a year later to take up the post of resident medical officer at the General Infirmary at Leeds, which he held for four years, and was then appointed part-time professor of anatomy at the early age of 26. Next year he took his M.D. degree at Aberdeen with highest honours. Wardrop Griffith identified himself with the interests and development of the Leeds Medical School, and it was largely due to his efforts that the present fine building replaced the humbler one in Park Street. He held the chair of anatomy until 1910, when he became professor of medicine, having been full physician at the General Infirmary since 1905. As a clinical teacher he showed the lucidity and mastery of style that had distinguished him in anatomical science. He founded the dermatological clinic, and later placed the study of heart disease in Leeds on a truly scientific basis. During the war of 1914-18 he served with the 2nd Northern General Hospital at Beckett Park and was put in charge of the cardiac centre in the Northern Command. For his war service he was created C.M.G. He became emeritus professor in 1925. Aberdeen University conferred on him the honorary degree of LL.D., and Leeds the honorary D.Sc. He had been a Fellow of the Royal College of Physicians of London since 1908 and represented Leeds University on the General Medical Council for nine years. After retiring from the headship of the Department of Medicine he continued to serve as honorary consultant for cardiac affections to the Ministry of Pensions in Yorkshire. He wrote numerous articles on diseases of the heart and circulatory system, and acted for a long time as local correspondent of this *Journal*.

Throughout his career Wardrop Griffith was distinguished by the highest personal integrity and loyalty to the ideals of our profession and by devotion to the School which his scientific attainments did so much to adorn. He was a past-president of the Leeds and West Riding Medico-Chirurgical Society and a member of the B.M.A. for 63 years. A memorial service was held in the chapel of the General Infirmary on Oct. 24.

The death on Oct. 14 at the age of only thirty of IAN M. DAVIDSON of Carlisle has caused a gap that might have been left by many an older man, for Davidson packed so much into his short life. From Rugby he entered Glasgow University and graduated in 1938. After a period as house-surgeon in the Glasgow Victoria Infirmary, he went as ship's surgeon to the Far East. At the outbreak of war he volunteered for service in the R.A.M.C., but was shortly discharged on medical grounds. He came to the Cumberland Infirmary, Carlisle, in 1940, first as house-physician and then as house-surgeon; spent a few months away from that institution in 1941, during which he wrote his M.D. thesis, and returned later that year as surgical registrar. During his tenure of that office he obtained the Fellowship of the Royal College of Surgeons of Edinburgh. In 1943 he was appointed honorary assistant surgeon to the Cumberland Infirmary, and subsequently surgeon to the E.M.S., consulting surgeon to the Victoria Cottage Hospital, Maryport, and surgeon to the City General Hospital, Carlisle. He was also an examiner in surgery for the General Nursing Council. Ian Davidson was blessed with unusual gifts of mind and body, and his engaging charm and genuineness won him many friends. He was a sound surgeon, with a deftness of hand that reflected a quick and steady brain, and the maturity of his judgment belied his youth. His young widow, Dr. Josephine Cartwright,

D.R.C.O.G., of Edinburgh, and their year-old daughter, sur him, and it is hoped that they and his parents (Mr. Nori Davidson, O.B.E., F.R.C.S., and Mrs. Davidson, of Glasg may be fortified by the good will of so many others who sh their sorrow and their loss.—T. MCL. G.

Dr. SIDNEY JOHN STEWARD died on Oct. 15, after about years of ill health, at Babbacombe, Torquay; whither he retired after about thirty years' work at Guildford, Surrey. was the son of John Alfred Steward, twice Mayor of Worces where he was born in 1879. He was educated at the Ki School, Worcester, and at Downing College, Cambridge, h ing scholarships at both those foundations; at Downing was captain of the Boat Club. Proceeding to St. Thom Hospital, London, for his clinical studies, he qualified M.R.C.S., L.R.C.P. in 1904 and took the Cambridge M.B. the same year; in 1909 he graduated as M.D., and later to the D.P.H. As an undergraduate he volunteered for ac service in the South African war with the 1st Battalion Suff Regiment, to which the Cambridge University Rifle Corps a contingent. After qualification he was house-surgeon at Brighton and Hove Hospital and then served a term as sh surgeon in the Union Castle line, after which he took an appo ment in the Colonial service as Government M.O. at Trinid Then he was assistant medical officer to the Devon Met Hospital, after which he became medical adviser in mei deficiency to the Surrey County Council and mental specia to their Education Committee; from these posts he retired 1944 after about thirty years' service. He held a tempor commission in the R.A.M.C. throughout the 1914-18 v mostly with the 1st Division, and was awarded the D.S.O. gallant behaviour in action during the retreat from Mons; retired with the honorary rank of major. He married M Edith Emma Murillo in 1910—she predeceased him early year; their only son died in infancy, one daughter survi them. He was a member of the British Medical Association to 1944, but held no office.

The death of Dr. CHARLES JAMES ROYSTON, who practi in the Moordown and Winton wards of Bournemouth, grieved countless numbers of patients and friends. Only few days before he was carrying on his busy day's work cheerily as ever. Dr. S. Watson Smith writes: Forty-six ye of age, Royston had crowded into his useful life an enorm amount of work. He was dominated by a high sense of du as a general practitioner he gave entire devotion to serving community, wielding an immense influence for good where he went. His cheerfulness, his humour, his gentle friendli and his sympathetic nature were an inspiration to all w knew him. With an evenness of temper that nothing seeme disturb, and a fine common sense, he addressed himself to e day's work with zest and zeal; making use of every minut and his working day lasted sixteen or eighteen hours, someti even longer. Royston was trained at Aberdeen under the Sir Ashley Macintosh, a great clinician whose memory cherished; there he had acquired his grasp of fundamentals o of first principles which guided him surely and successfully his bedside work. The means he employed were wisely simp though up-to-date in his knowledge of drugs, he fully appr ated the value of the old well-tried remedies, which he m use of every day. Gentleness towards the suffering marked Royston did. His life was packed with good deeds, and is to measured by these rather than by the length of years gi him; no life was more worthily spent. Alas, Royston wor himself to death. He was little interested in himself, alw thinking last of his own comfort and interests. He wor harder than most in the hardest-worked profession, a seemed never to tire or become jaded. Royston was driv to exhaustion by an over-large general practice that demand all his time and attention day after day without intermissio rest and enough leisure-time he never got, but he did complain. Any who relied upon him in sickness, and numb less others who knew him, will, now that he is gone, have o one thing left—a grateful heart. His name and fame will b be remembered in North Bournemouth and far beyond.

News has been received of the death of Mr. GEORGE VERN LOCKETT, of Kingston, Jamaica. He studied medicine at a University of Edinburgh, graduating M.B., C.M. in 1890, a obtained the F.R.C.S.Eng. in 1895. He had been senior resid medical officer in the Public Hospital at Kingston and v elected honorary consulting surgeon to that institution in 19 He joined the B.M.A. in 1891, represented the Jamaica Bra at the Centenary Meeting in London in 1932, and was elec president of his Branch in the same year, afterwards serving the Branch Council. He received the distinction of Fellows of the American College of Surgeons in 1914.

Medical Notes in Parliament

HEALTH SERVICE BILL

Committee Stage Completed

When the Committee Stage of the National Health Service Bill was resumed in the House of Lords on Oct. 22 Lord AMMON intimated that it had been agreed to complete this stage on the following day. The Report stage would be taken on Oct. 28.

On Clause 20, discussing the provision of services by the local health authority, Lord HENLEY moved that any counter-proposals made to the Minister by voluntary organizations, councils, boards, or other authorities should also simultaneously be transmitted to the local health authority.

For the Government Lord LISTOWEL said it was inconceivable that the Minister would modify the local health authority's scheme in the light of objections lodged by other authorities in the area without giving the county council or county borough council a fair chance of commenting on the views of its critics. Lord HENLEY withdrew his amendment, and the House agreed to Clause 20 as also to Clause 21 and Clause 22.

Lord MUNSTER moved an amendment to Clause 23 (Midwifery) which would enable the local health authorities to make arrangements with maternity and general hospitals as well as with voluntary organizations to secure that the provision of midwives for attendance on women in their homes was adequate.

Lord ADDISON said he would look into this in a friendly way before the Report stage. The teaching hospitals had arrangements for attending cases in their own homes, sometimes with students and sometimes without. It was likely that arrangements might have to be made with respect to the boards of governors of teaching hospitals. The amendment was withdrawn and the House agreed to Clause 23.

Clause 24 was approved after Lord MAUGHAM had moved and withdrawn a drafting amendment on the duties of health visitors. Lord LLEWELLIN, during the discussion of this amendment, said the view was widely held that the words of the Clause as they stood might be held to justify a presumption that persons who were not duly qualified medical practitioners should be appointed to look after those suffering from illness. In answer to this Lord JOWITT gave an assurance that there was no intention that health visitors should come between the doctor and the patient. Health visitors had no right to force their way into a house. The Committee then agreed to Clause 24 and to Clause 25 (Home Nursing).

On Clause 26 Lord LISTOWEL moved an amendment to ensure Ministerial approval for the exercise by the local health authority of power to arrange for vaccination or immunization against diseases other than smallpox and diphtheria. The Committee agreed to the amendment and to the Clause as amended. Clause 27 (Ambulance Services) was accepted without amendment.

Lord AMULREE on Clause 28, relating to the prevention of illness, and care and after-care, moved to insert the care of the aged among the purposes for which the local health authorities could make arrangements. He said if Parliament attempted to separate old people who were sick from old people who were healthy, they would get into great difficulty. In the next five or six years the number of persons over 65 in this country would increase to about 8,000,000, and of these many would need to be taken care of in some sort of home. There was a danger that the hideous Poor Law infirmary might reappear.

Lord LISTOWEL said the amendment went far beyond the limits of a Bill which dealt with public health. Care of the aged who were not sick would be dealt with in forthcoming legislation for the abolition of the Poor Law. On this assurance Lord AMULREE withdrew his amendment.

Lord MUNSTER moved to amend the list of persons for whom the local health authority could provide by leaving out "persons suffering from illness or mental defectiveness or the after-care of such persons" and inserting "of mental defectives or the after-care of persons who have suffered from illness." He said that under the Clause as it stood the local authority might and if directed by the Minister must make arrangements for the care of persons suffering from illness. It would be possible for that obligation to be fulfilled by the introduction of a whole-time salaried medical service side by side with the general practitioner service.

Lord LISTOWEL said it was not the intention of the Government to introduce a full-time salaried medical service, and the Clause as it stood could not give effect to such a purpose. Lord MAUGHAM said that again and again in this Bill very

wide clauses put into the hands of the Government or local health authorities powers which they were not intended to have.

Answering Lord LLEWELLIN, Lord LISTOWEL said the expression "after-care" in this Clause meant care involved after hospital treatment, not care after a patient was finally cured. A number of things were essential to speed up recovery and prevent the spread of infection. An instance was the provision of bedding for a patient suffering from tuberculosis who was waiting for a place in a sanatorium. This would be provided by a local authority and not by the doctor. Lord ADDISON instanced the provision of hot-water bottles. The words which had been challenged were intended to secure that services of that kind were made the duty of the general health scheme. Lord MUNSTER withdrew his amendment and the House agreed to Clause 28 as amended. It also approved without discussion Clause 29 and Clause 30.

Executive Councils

On Clause 31 Lord LUKE moved to provide that in constituting a council the proportion of the whole number of members of the council to be appointed by bodies representing medical practitioners, dental practitioners, and persons providing pharmaceutical services should not be less than the corresponding proportion under paragraph 1 of the Fifth Schedule.

Lord JOWITT said there were liable to be exceptional cases where, owing to the smallness of an area or the sparseness of its population, it was difficult to get an effective council of twenty-four. The effect of the amendment would be that the Minister would always have to deal in multiples of twenty-four. In a council of 16 it would be impossible to have one and a quarter chemists, the proportion provided by the Fifth Schedule. Lord LUKE withdrew his amendment.

Lord ADDINGTON moved and withdrew an amendment designed to ensure that every executive council and joint committee should submit to the Minister a scheme for the exercise of its functions under Part 4 of the Act and that a copy of this scheme should be sent to every local authority in the area with power to the authority to make representations upon it to the Minister. The House then agreed to Clause 31 and also to Clause 32.

Medical Certificates

On Clause 33 Lord HENLEY moved to provide that regulations might be made for the purposes of complying with any requirements arising out of a contract of employment. He said the Clause provided that the executive council should make arrangements with medical practitioners for personal and medical services for potential patients in their area and should make regulations as to what these personal medical services were to be. A subsection of the Clause related to the issue to patients of certificates "reasonably required by them under or for the purposes of any enactment." He explained that the amendment was based on the assumption that these medical certificates would be issued to patients free of charge. The object of the amendment was to extend the issue of free certificates to patients covered by the provision of conditions of service in their employment entitling them to continue on full wages for the periods during which they were incapacitated.

Lord JOWITT said doctors' obligations in national health insurance work were limited to giving certificates required in that connexion. The Bill widened the doctor's obligations to the provision of certificates reasonably required under any enactment, which would include regulations. A certificate would be obtainable free of charge, for instance, for an expectant mother to obtain priority food. The amendment required the doctor to give a certificate for a private purpose which had nothing to do with any Act, any insurance scheme, or any regulations. Where they were not dealing with public enactments he did not see why the doctor should not be allowed a reasonable and proper charge. Under the Insurance Act which was to replace the workman's compensation scheme the case would be covered where a county court judge asked for a doctor's certificate. Lord HENLEY withdrew his amendment.

Terms and Conditions for Practitioners

On the same Clause 33, Lord LLEWELLIN moved to add the following subsection:

"Regulations prescribing the terms and conditions upon and subject to which any service would or could be required to be rendered by any medical practitioners under or in pursuance of the provisions of this Act shall be made not less than 3 months before the day which is the appointed day for the purposes of subsection (1) of section 34 of this Act."

Lord Llewellyn said this was an important amendment. Clause 34 (1) provided that every medical practitioner other than a paid assistant who wished to provide general medical

services should be entitled on making an application at any time before the appointed day in the prescribed manner to be included in the lists of medical practitioners. It was reasonable that these men should have an adequate opportunity of being told what the conditions were going to be when they came in. There was a strong desire in the medical profession to know these terms a reasonable time in advance so that they would be able to decide whether or not they should come into this service.

The LORD CHANCELLOR (Lord Jowitt) said that the words of the amendment were defective. It would extend to hospital services, whereas the House was dealing with medical services. That point could be put right. He sympathized with the substance of the amendment. It was only right that the medical profession should know the terms and conditions for a longer period even than three months, but he did not wish to tie himself down in the Bill. After all, the terms would be negotiated with representatives of the medical profession, who would keep their constituents acquainted with the matter as it proceeded. He would do his best to see if he could get the negotiations through to provide more time than three months. In reply to Lord CRANBORNE, who appealed to the Government to accept this amendment, the LORD CHANCELLOR said he had heard April 1, 1948, suggested for the appointed day. There would be very difficult negotiations, but he thought the Government could give at least six months' notice. It ought to aim at this as a minimum.

Method of Payment

Lord LLEWELLIN withdrew his amendment. He then proposed another subsection to run:

"The remuneration to medical practitioners undertaking to provide general medical services in pursuance of the provisions of this Act shall be fixed by the capitation method except in any cases where the Minister on the recommendation of the Medical Practices Committee considers that exceptional circumstances necessitate remuneration on a different basis."

He said the amendment went to the root of whether the doctor should be paid by salary, as some members of the Labour Party had wanted, or by a capitation fee or by a mixture of salary and capitation fee. No indication had been given in the House of Commons of what proportion was to be by salary and what proportion by capitation fee. The Conservative peers believed that the right way was to pay by capitation fee but realized there were areas where the capitation fee did not meet the case. Where the Medical Practices Committee recommended to the Minister that it was necessary to attach a salary in order to increase the number of medical officers in an area, the Minister could under the amendment approve, and the salary would automatically come in. But where the service could be worked without the new departure of trying to make a State salaried medical service, then the independence of the doctor should be kept as in the past. With a salaried service the doctor became more the servant of the State than a servant of the patient.

Lord MORAN said this question roused the misgivings of many doctors who like himself were satisfied, generally speaking, with the hospital provisions but had misgivings about what would happen to the general practitioner. His friends always asked two questions. The first was whether, when the Bill became law, the medical profession would be able to attract the exceptional man in competition with the other professions. The second was whether, when the Bill became law, the medical profession could provide conditions so that a man entering medicine could be as good and as efficient as any in the past and would remain keen. The proposal to pay a basic salary required more justification than had been given. It was said that any practitioner entering medicine might have financial difficulties in his first year or two and that a basic salary of £300 or £400 per annum would give some security. Would the basic salary really act in that way? Was it proposed that the Ministry of Health should go on paying doctors basic salary if they did not get any patients in their first year or two? If that was not the intention of the Ministry then it was clear that if the doctor secured patients to an amount equivalent to the basic salary this measure of security was no longer necessary. There was a good deal to be said for the alternative of a capitation fee. In past years he had been asked to advise the Services how they could get keen men and keep them keen. His investigation showed that it was impossible, with brilliant exceptions, to keep the men as keen in whole-time salaried service as in general practice where the competitive stimulant was present all the time. It was sometimes said there was something derogatory in competing for patients; he was sure the Lord Chancellor would not subscribe to that.

Lord HORDER said it had been reported during the previous two days that the Minister of Health was on better terms with the British Medical Association than he had formerly been.

He thought Mr. Bevan got some satisfaction out of this. It were true he could do nothing more likely to take the good relations a stage further than by accepting this amendment. Statements that there was no intention in this Bill to nationalize the medical profession could be made *ad nauseam* but there would remain fixed in the minds of members of the profession the idea that that was the final intention of the Government and of the Ministry of Health. There was equally strong feeling against this method of paying the doctor in part by a basic salary and in part by a capitation fee which decreased with the number of patients whom the doctor treated. A ceiling was fixed above which no doctor could rise by energy, by genius, or by any other quality which Parliament wished to encourage in members of the profession. Doctors had it fixed in their minds that this was the most vital spot at which the Government could attack the independence of the doctor. It had been stated by Mr. Herbert Morrison that this was the first step toward a complete policy. What was that complete policy if it was not to make all doctors whole-time salaried servants of the State? It had been said in the Commons that the time was not yet ripe for a full-time salaried service for every doctor. The remark implied that the Government intended to pluck the fruit when it was ripe. He suggested to Ministers that it would be wise to assure themselves of extra confidence in the minds of the medical profession by accepting the amendment. Mr. Bevan had said that without the doctors' co-operation the scheme must fail, but the doctor wanted it to succeed and believed there were good points in the Bill. He thought the Bill a bad one but would like to make it less bad and had committed himself to the belief that the doctors would do their utmost to make it work. Doctors could not strike. They must continue their work and they must have State support in continuing their work. It was for the State to help the doctor and not so much for the doctor to help the State. One other word. The doctor was not an altruist when he started in his profession. He was an altruist in proportion to his professional success. The Government must not expect from the young practitioner entering upon a career, which was notoriously expensive both for his parents and for himself, the grade of altruism which it got from those members of the profession who had "arrived" and were therefore able to go to the counsels of the Government. Doctors agreed that it was the duty of the State to improve the machine, and that when the State had improved it the doctor must work it. An unwilling worker would not even give the scheme the trial which deserved.

Lord ADDISON agreed that the amendment affected an element vital in the whole scheme of the Bill. He recalled that 34 years ago he had been involved in the same controversy when medicine went up and down the country heard speeches telling them the dreadful things that were to happen. They did not happen and he himself had been one of those who said they would not happen. He disagreed now with Lord Moran as much as he had done with the critics at that time. He thought Lord Moran's faint praise would not stimulate the hearty assistance in working the scheme which he said he desired. Lord Addison said that he himself had been largely in charge of the negotiations relating to the original capitation fee. Frankly he had been exceedingly disappointed at the way in which it had worked. In contradiction to Lord Moran he emphatically thought there was something derogatory in competition for patients. The whole tradition and practice of the medical profession was to frown on unnecessary competition for patients. The profession was right in that matter. There had been a number of cases when men had enlarged their list not because of their skill but by doing other things which attracted people to them. There were good reasons for the system proposed in the Bill. In the first place nobody wanted inflated lists. An inflated list meant that a man could not give the detailed personal attention to his patients which he ought to have. The Government had on that account adopted the system proposed in the Bill and not because it had sinister designs. A second reason for the system was that it would be necessary to try to attract young doctors to country districts where there were relatively few people. The right way to do that was to let these young men know that they would have something to live on. Further, there were areas inadequately served by medical men, and in those areas the attraction of a basic salary would be influential in helping the Government to get the service it desired. The method of payment could not be prescribed in the Act, it must be left to negotiation. It was not even prescribed in the original Health Insurance Act. Nobody envied Mr. Bevan in the negotiations he would have to conduct on this matter in the next year or two. The precise procedure would have to be negotiated and so would the relation between the basic salary and the capitation fee. Lord Addison did not think it would be possible to devise a system whereby these could be standardized. In remote districts the

basic salary would probably have to be higher than in other places. There would still be an element of competition, which, so far as it was wholesome and proper, none of them would wish to damage. The Government could not accept the amendment.

LORD CRANBORNE said the Government had been wise not to put up the Lord Chancellor to speak on this amendment, for he would have been embarrassed in dealing with the argument that competition was of value in a profession. The House contained many of the greatest authorities on all questions and listened to their advice. Speaking for himself he had come to the conclusion, taking into account the experience of Lord Horder and Lord Moran and their knowledge of the individual members of their profession, that the case they had made out was unanswerable. For that reason the Opposition felt obliged to take the matter to a division.

LORD READING said that in his own profession he had seen too many young men obliged to abandon their career in the early stages because they had no means of going on with it. He knew of others who desired to enter the medical profession but had been similarly barred. Perhaps they had been able with Government grants to take the necessary qualifications but had been left with nothing to enable them to embark upon the profession afterwards. For these reasons his friends did not feel disposed to oppose the Government. He suggested that the Government should give an assurance that it was not in their mind, in the present condition of affairs, to embark upon a wider scheme of State medical service and State control of service. LORD ADDISON said he could and did give that assurance.

On a division the amendment moved by Lord Llewellyn with regard to the remuneration of medical practitioners was carried by 53 to 37.

Certificates: Partnerships

LORD MAUGHAM moved to insert a subsection to provide that nothing in the Act should be deemed to debar and no regulation should be made to debar any medical practitioner from giving or issuing any certificates under this or any other Act in relation to or for the purpose of any of the service provided under this Act on the grounds that such medical practitioner was not included in any particular list of medical practitioners undertaking to provide general medical services. He said the amendment was brought forward to relieve the anxiety of doctors who did not at present intend to go on the list and feared that regulations made under the Clause might preclude an independent doctor from giving certificates which were necessary under Acts of Parliament. The LORD CHANCELLOR said that under the Bill there was no distinction between the independent doctor and the doctor who was operating under the public service. That assurance had been carefully checked. LORD MAUGHAM withdrew his amendment and Clause 33 as previously amended was agreed to.

On Clause 34 (distribution of medical practitioners providing services) the House accepted an amendment proposed by Lord LISTOVEL to ensure that an appeal by a doctor against a decision of the Medical Practices Committee must be decided, as well as heard, before the successful applicant was allowed to take up a new practice. LORD MUNSTER then moved to add two new subsections in the same Clause. The first provided that the Medical Practices Committee and any Executive Council, as also the Minister, in determining appeals, should have regard to a desire expressed by the members of a family to work together and to a desire expressed by a medical practitioner to succeed to the practice of his father or other near relative. The second draft subsection proposed that in considering candidates for a vacancy among medical practitioners practising together as a partnership the Medical Practices Committee and any Executive Council should consult the remaining members of the group before selecting the candidate to fill the vacancy. LORD MAUGHAM supported the amendment and said that unless it was clear that a son had a fair chance of succeeding to his father's practice practitioners with children who they hoped would become doctors would be disposed not to come on the list.

LORD LISTOVEL said that the existence of family or group relationships would be a material factor which the Executive Council could not fail to take into account in advising the Medical Practices Committee about an application to practise, and it would also be considered by the Minister in the event of an appeal. The competence of the doctor himself would be an important consideration, but it was obvious that other things being equal preference would be given to an applicant having ties of this kind. He offered to consult Mr. Bevan about the amendment and see if it was possible to devise a form of words which could be put in the Bill. LORD MUNSTER withdrew his amendment and Clause 34 as amended was agreed to.

Sale of Goodwill

On Clause 35 (prohibition of sale of medical practices) LORD MAUGHAM moved to amend in subsection 2 the words "any person who sells or buys the goodwill or any part of the goodwill of a medical practice which it is unlawful to sell by virtue of the last foregoing subsection shall be guilty . . ." by inserting the word "knowingly" after "who." He said this amendment was necessary to carry out the intention of the Clause as it stood. Under subsections (3), (4), (5), and (6) certain transactions were deemed to be a sale of the goodwill for the purposes of subsection (1) of the Clause. The consequence was that there might be people who committed what was made a crime by subsection (1) without knowledge of the circumstances in which that crime had resulted. There might be a sale under which a medical practitioner who was retiring sold his furniture or medical equipment, some of which was now very expensive, to a new practitioner who was coming in. The vendor could not know whether he would be able to establish or whether the purchaser would be able to establish that no part of the consideration was given for goodwill or part thereof. Similarly a tribunal might at some subsequent date say that the consideration for the sale, letting, or other disposition of premises for the purposes of a practice to another medical practitioner was substantially in excess of what might reasonably have been expected if the premises had previously been used for purposes of medical practice. Then both parties were held to have committed a crime. LORD MAUGHAM said his opinion was that the provisions of Clause 34, except so far as they related to the sale of goodwill by medical practitioners who were on the list on the appointed day, were ill-considered and went much too far. He had very strong grounds for asking the Government to insert the word "knowingly."

The LORD CHANCELLOR noted that no one was attacking the general principle of the prohibition against the sale of medical practices. The House would agree that if a man was getting full compensation from public funds under Clause 36 it was undesirable that he should also get compensation or payment for the sale of his practice from private sources. In subsection (2) the word "knowingly" was unnecessary because it was obvious a man would never sell or buy the goodwill of a medical practice unless he knew what he was doing. That sort of thing was not done when suffering from some mental aberration, or at least not often. In subsection (3) the Bill was dealing not with a direct and obvious sale of goodwill but with premises. There the Government had put in the word "knowingly," and in some of the later clauses it had again put in words enabling the defendant to answer a charge by saying that remuneration was not fixed by reference, for instance, to the taking of a new partner. His observation about compensation applied to existing people. Every form of evasion had to be stopped if possible and the clauses had to be stringent. There were two safeguards. Anybody in doubt who did not want to run his neck into a noose could go before the Medical Practices Committee. If he revealed the facts and they said "that is all right" then their certificate was complete protection. In the second place the Bill said the prosecutions could only be brought by the Director of Public Prosecutions and the Director could get a report from the Medical Practices Committee. He believed there was adequate protection to prevent an innocent person from getting into trouble about this thing.

The amendment proposed by Lord Maugham was negatived. The House accepted an amendment moved by the Lord Chancellor to correct a clerical error and make it clear that a fine could only be levied after conviction.

In the same Clause, subsection (3) commencing "where any medical practitioner or the personal representative of any medical practitioner knowingly sells or lets premises previously used by that practitioner for the purposes of his practice," LORD MAUGHAM moved to leave out "or the personal representative of any medical practitioner." He said in an ordinary goodwill the name was a great element, but in the case of a doctor goodwill had nothing to do with the name because the incoming practitioner had to carry on the business under his own name. He got very little advantage from the premises *per se*. Goodwill meant nothing more than that the man who was selling was required to give some assistance which might be great or small to the man who was purchasing. In the ordinary way the practitioner who was selling went round with the new practitioner and introduced him to the patients. If he was a celebrated surgeon there was no goodwill at all. The eminent medical practitioners who sat in the House of Lords had absolutely no goodwill they could sell because their business was connected with their own skill or genius. But the ordinary country doctor who agreed to help with an introduction might give some sort of benefit. Of course an Act of Parliament could say that a widow who sold the premises in

which she had lived with her husband for 20 years was liable to be treated as if she had committed a crime if somebody thought she had got substantially too much for them.

The LORD CHANCELLOR said that where a widow received compensation out of public funds in respect of a practice she should not get compensation for the same practice out of private funds. Lord Maugham was wrong in arguing that because a doctor had died there was no sale of goodwill. The fact that a place had been used as a doctor's surgery and consulting room for a long time, that patients had been accustomed to come there, and that it was fitted up might enable a higher price to be secured for those premises if sold to a doctor. One of the most important features in a sale of goodwill was the transfer of the case books. That constituted a very valuable element. It had to be proved against the widow to convict her that she was selling at a price substantially in advance of the price she would have received had she been selling to a person who was not a doctor. He could not see why Parliament should not prevent her doing that, and he maintained that the words "or the personal representative of any medical practitioner" ought to remain.

Lord MAUGHAM repeated that he was dealing with the case of the personal representative of a medical practitioner who had died after the appointed day. He had never heard anyone suggest that the handing over of a case book was a sale of goodwill. He asked the Lord Chancellor to reconsider what had been said.

The LORD CHANCELLOR said he would go into the matter again with his legal advisers, and Lord Maugham withdrew his amendment.

Clause 35 as amended was agreed to, as were Clauses 36-39. Pharmaceutical services, general dental services, and supplementary ophthalmic services are covered in Clauses 38-41. An amendment moved by Lord TWEEDSMUIR to Clause 40 was withdrawn and the Clause was agreed to. On Clause 41 (supplementary ophthalmic services) Lord CECIL had down amendments designed to secure provision of treatment for the deaf as part of the hospital and specialist services, "putting ears on the same footing as eyes." He moved the first of these, and was supported by Lord HORDER, who said that defects of hearing had never been given the same prominence as defects of sight, partly because the study of the ear had not the same fascination as study of the eye. There was a great opportunity in the new medical services for research and study of the deaf person. He warned the House against confusing the aural medical practitioner and the maker of hearing aids. Lord LISTOWEL said the service which Lord Cecil desired for the deaf would be better carried out by Part II of the Bill, by the hospital and specialist services. He believed the deaf numbered about 400,000 against 4,000,000 who suffered from defective vision. Lord Cecil withdrew his amendment and Lord LISTOWEL moved a series of amendments to make clear in the Bill the distinction between ophthalmic opticians and dispensing opticians. The House agreed to the amendments and to Clause 41 as amended.

Disqualification of Doctors

On Clause 42 (disqualification of practitioners) Lord LISTOWEL moved drafting amendments which were accepted. Lord READING moved to leave out subsection (4) which runs:

"An appeal shall lie to the Minister from any direction of the Tribunal under the last foregoing section, and the Minister may confirm or revoke that direction."

He moved to substitute:

"(4) Any person aggrieved by a direction of the Tribunal either under the preceding subsection or under subsection (8) of this section may within one month after the date on which notice is given to him by the Tribunal of their direction appeal against the direction in manner provided by Rules of Court to the High Court, and in any such appeal the High Court may make such order or give such direction in the matter as it thinks fit."

The Tribunal itself, Lord Reading said, consisted of three persons, of whom one only was a person of legal experience. If it decided that the continued inclusion of an individual in a list would be prejudicial to the efficiency of the service it could either exclude him from a particular list on which his name appeared or it could exclude him from any list anywhere in the country of practitioners employed under the National Health Service Act. These were formidable powers to entrust to any tribunal where only one member had legal experience, because as the service grew and embraced a greater proportion of the medical practitioners exclusion from it was going to mean professional death to the person concerned. The next step under the Bill was that the person on whom this sentence of professional death had been imposed could appeal to the Minister who employed him for this purpose and came into this hearing to all intents as a party. The Minister could depute the hearing of the appeal to some person on his behalf.

The House knew nothing about this person. He might be a Civil Servant who himself was subject to the Minister. In that event the Minister was master not only of the appellant to the Tribunal but also of the judge as well. That must be an intolerable position.

Lord SIMON asked the Lord Chancellor whether he thought that the argument of Lord Reading could reasonably and properly be withstood.

Lord MESTON said there were certain things that a doctor must not do, and if he did them he was liable to be found guilty of gross professional misconduct and in the normal event would appear before the General Medical Council. This Bill had nothing to do with the G.M.C., and the Government had stated in the House of Commons that gross professional misconduct did not come within the words "prejudicial to the efficiency of the services." The Bill, however, did not say so; it made no such limitation. A doctor might do many things which might not be professional misconduct. They might be on the borderline or might concern his medical duties as apart from his moral conduct. He might have a tendency to absorb too much alcohol. He might prescribe the wrong medicines or be negligent or lazy. All these things came within the words "prejudicial to the efficiency of the services." Was it really suggested that a man who had devoted his whole life to medicine should be professionally destroyed by the report of an inspector which was probably not read by the Minister?

The LORD CHANCELLOR said the House was fighting over a well-trampled battleground. The matter had been very closely considered, and it was one on which the Government was bound to stand. The Bill was a development of the old National Health Insurance Act, under which the removal of a doctor from a list was a matter for the Minister and for the Minister alone. Lord Jowett said he had been closely connected with that Act and had never heard a single complaint from any doctor about the way it worked. The Government did not want the doctors to become Civil Servants; but they were in some sense in public employment, and the analogy between employer and employed was obviously there. If the Minister were entrusted with the duty of securing a service which he considered to be efficient it was impossible to ask him to deprive himself of the right of dismissal.

Lord CRANBORNE said he did not know whether there was a demand for an appeal to the High Court from the doctors, but he had come across a demand for greater protection than was given under the Bill as it stood at present. On this point the doctors were extremely nervous. It was essential that in the early inquiries the doctors should be given the benefit of counsel and of calling evidence. He asked the Government to consider before the Report Stage if something of that kind could be done. The LORD CHANCELLOR undertook to see if he could find a solution to that point.

Lord READING said he did not think that the matter had been advanced much further, and with reluctance he withdrew his amendment.

Miscellaneous Clauses

On Oct. 23 Clause 42 as already amended was agreed to. On Clause 43 (powers of Minister where services are inadequate) Lord ADDISON recognized the misgivings which the comprehensive words in the Clause promoted. He said the intention was that the Minister should be able to take action to deal with a particular shortage or emergency which had been discovered. He thought the Government should consider whether it could frame words which would meet the needs of the emergency instead of being of general application. Lord Llewellyn withdrew an amendment, and the House agreed to Clause 43. It also accepted Clause 44 (recovery of charges in respect of certain appliances and dental treatment) after Lord Llewellyn had withdrawn an amendment. Clauses 45-47 were agreed to without discussion.

On Clause 48 (provision of courses for medical and dental practitioners) Lord READING moved an amendment to authorize the provision of refresher courses for nurses employed in connexion with services provided under any part of the Act. Lord HORDER supported the amendment. He said there was totally inadequate reference to the work of nurses throughout the Bill. In the House of Commons Mr. Bevan had said the matter would adjust itself because the nurse could always go back into a hospital. That was a totally inadequate means of dealing with the postgraduate training of nurses. Lord ADDISON said that in this clause for the first time the State went out of its way to provide for medical men to have postgraduate training and to get refresher courses, but not one noble lord said "Thank you." This was amazing. There was no place in the world which had equal facilities to London for postgraduate training, and the Government intended to do whatever it could to help the medical profession and the teaching colleges so to develop. Nurses were different from the practitioners dealt with in Part IV of the Bill. They were whole-time servants and not

paid as he hoped the doctors would be—partly by capitation fee. It was to help men who were not whole-time servants to get this training that the provision in the clause was inserted. Those who were whole-time servants, such as nurses and medical men employed whole-time, would be provided with facilities and would be expected to undergo regular refresher courses. LORD READING withdrew his amendment.

Clause 48 was agreed to, as were Clauses 49-52. Clause 53 (grants to local health authorities) was approved after discussion. Clause 54 was agreed to, and so, after discussion, was Clause 55. Clauses 56-59 were agreed to; also Clauses 60-65. On Clause 66 (superannuation of officers) LORD LISTOWEL, for the Government moved in subsection (2) to leave out "so employed who leaves his employment" and to insert "who leaves employment in Scotland or Northern Ireland entitling him to participate in superannuation benefits (whether provided under the said Act or otherwise)." He said the amendment was to confirm the pension rights of health officers which would otherwise be prejudiced. Suitable entrance to the health services in England might come from the Scottish local government service. The amendment had been drafted to cover them. The amendment was agreed to, and Clause 66 as so amended was accepted. Clauses 67-71 were agreed to. After discussion the Committee agreed to Clauses 71, 72, and 73. On Clause 74 (regulations) LORD MUNSTER moved that no regulations should be made to determine the areas for which the regional hospital boards were to be constituted unless a draft had been laid before Parliament and had been approved by each House. The LORD CHANCELLOR said the regulations about the regions would be made separately, and Lord Munster withdrew his amendment. Clauses 75-77 were agreed to.

On Clause 78 (interpretation) the House accepted an amendment proposed by LORD LISTOWEL stating that a dispensing optician meant a person having the prescribed qualifications for the fitting and supply of optical appliances. It also accepted an amendment that ophthalmic optician meant a person having the prescribed qualifications in optics, including the measurement of errors of refraction, in orthoptics, and in the fitting and supply of appliances. LORD MAUGHAM suggested that the word "specialist" should also be defined. It occurred constantly in the Bill, and in practice there would often be a necessity to know whether a man was specialist or not. There should be some definition making it reasonably clear that only if they did not undertake general practitioner work were they to be treated as specialists. LORD MORAN said what Lord Maugham suggested would not be practicable, because there were only half the specialist consultants who were needed for the purpose of the Bill, and during a long period—it might be ten years—a man might be both general practitioner and consultant. The General Medical Council had gone closely into a suggestion that there should be a register of medical consultants, but he did not think that was likely to be pressed. He considered it impracticable. Clause 78 as amended was agreed to and the remaining clauses agreed to.

Hospital Committees

The first schedule was agreed to, as was also the second schedule. In part two of the third schedule (regional hospital boards, hospital management committees, and boards of governors of teaching hospitals) LORD MUNSTER moved to change the provision that a hospital management committee shall include persons appointed after consultation with the senior medical and dental staffs. He desired to substitute consultation with a committee representing this staff. LORD MORAN said he thought the amendment really meant that the medical staff as a whole should be consulted. A medical staff was a democratic body and did not recognize any distinction between junior and senior members. The LORD CHANCELLOR agreed that where there was a medical committee the whole body ought to be consulted. The Minister intended to encourage the formation of these committees everywhere. Where there was no committee the Minister's intention was to consult with the consultants and specialists—not the housemen. He gave an undertaking that where there was a medical staff committee that would be consulted as an entity without picking out the older and distinguished members. Lord Munster withdrew his amendment. The Lord Chancellor accepted an amendment proposed by LORD LUKE to provide that before making appointments to fill vacancies the board should also consult the committee. LORD MORAN moved that on the board of governors of a teaching hospital not more than two-fifths of the members appointed by the Minister shall be nominated by the University with which the hospital is associated. The proposal of the Bill was for one-fifth to be so appointed. The LORD CHANCELLOR thought that the amendment would overweigh the teaching proportion. Another fifth were to be appointed by the medical and dental teaching staff. A teaching hospital had the threefold function of treatment of patients and of research and of teaching hospitals. For the future there must not be an undue emphasis on the teaching side.

LORD MORAN said it was admitted in the whole profession that the patient's interest must always be looked after. In the last 25 years he had seen a weaning of public opinion from the idea that a teaching hospital did not exist for the care of the sick but for the teaching of knowledge. The amendment was withdrawn, as was an amendment moved by Lord Moran to provide that not more than one-fifth of the personnel of the board of governors of a teaching hospital should be nominated by the medical staff committee of every hospital in the group. He recalled that in the provinces a teaching hospital often comprised two or three institutions. The LORD CHANCELLOR promised to see whether suitable words to deal with the point could be inserted on the report stage. He refused an amendment to provide that before making appointments to fill vacancies the Minister should consult the board.

The third schedule as amended was agreed to, as was the fourth schedule after rejection of amendments dealing with the constitution of health committees. The fifth, sixth, and seventh schedules were agreed to with a consequential amendment in the seventh. The eighth schedule was agreed to. On the ninth schedule (amendment and appeal of enactments relating to persons of unsound mind and mental defectives) LORD LISTOWEL moved an amendment to enable the medical superintendent of a resident hospital to allow to be sent out on trial a patient received there under contract. The amendment was accepted, as were other consequential amendments moved by Lord Listowel, and the schedule as amended was agreed to. Consequential amendments were made in the tenth schedule, one of which substituted the words "Minister of Health" for "Board of Control" in Section 92 of the Children and Young Persons Act, 1933. The tenth schedule was then agreed to, and the Committee Stage was concluded.

REPORT STAGE

The National Health Service Bill was considered on the Report stage in the House of Lords on Oct. 28.

On Clause 7 the LORD CHANCELLOR moved an amendment—which was agreed to—to ensure that any gifts made to voluntary hospitals between the date of the passing of the Act and the appointed day should be used according to the wish of the donor.

The LORD CHANCELLOR moved a further amendment to provide that every board of governors and hospital management committee should ensure, so far as was reasonably practicable, that the objects of an endowment and observance of any conditions attached to it, including, in particular conditions intended to preserve the memory of any person or class of persons, were not prejudiced. He said that he felt very strongly that it would be wrong to interfere more than could be helped with the wishes of people who had given money to hospitals, although there must of course be a certain amount of latitude.

LORD MAUGHAM, who had tabled an amendment in the same sense, congratulated the Government on having found a means of meeting the general wish of the House. LORD LLEWELLIN thanked the Government for having met the Opposition in the amplest possible way. The amendment was agreed to.

Clinical and Research Facilities

An amendment to Clause 12, inserting in the Bill the duties of hospital management committees, was agreed to. The amendment consisted of the following new subsection:

"(2) It shall be the duty of the hospital management committee of any hospital or group of hospitals, subject to and in accordance with regulations and such directions as may be given by the Minister or the Regional Hospital Board, to control and manage that hospital or group of hospitals on behalf of the Board, and for that purpose to exercise on behalf of the Board such of the functions of the Board relating to that hospital or group of hospitals as may be prescribed."

The amendment also added the following new paragraph: "(a) to provide for the university with which the hospital is associated such facilities as appear to the Minister to be required for clinical teaching and research."

LORD ABDINGTON moved an amendment to Clause 19 to secure the delegation to non-county boroughs of a substantial part of the control of the day-to-day duties in connexion with their health services, if they applied for that authority. LORD O'HAGAN said he hoped it would also be possible to include urban district councils. LORD LLEWELLIN said that as an amendment had been accepted making mandatory the delegation of certain powers by the L.C.C. to London boroughs, he thought it right that the counties should be similarly treated.

The LORD CHANCELLOR said that his colleagues in the Coalition and in the present Government felt strongly that where there was a local authority service in any area there must be

one local authority and not several. The proposal that partition of the service should be permissive impinged on another vital principle. A decision must be taken that the thing should be done one way or the other, and not left to be a matter of bargaining or political agitation in the future. The amendment was withdrawn.

Terms of Service

On Clause 33 Lord LLEWELLIN moved that medical practitioners should be given at least three months' notice of the conditions of the medical service before having to decide whether they should enter it or not. The LORD CHANCELLOR said that he could not accept the amendment, but he gave an assurance that the period of notice to be aimed at should be six months. The amendment was, by leave, withdrawn.

The LORD CHANCELLOR accepted an amendment to Clause 34, moved by the EARL OF MUNSTER, to enable effect to be given to a desire by any practitioner to practise in partnership.

Lord CECIL moved an amendment to Clause 41, on arrangements for general dental services, requiring that provision should be made in the new health service for the treatment of deafness. Lord ADDISON, for the Government, said that the provision desired by Lord Cecil could not be made on the Clause before the House, but he gave an assurance that before the Third Reading of the Bill he would do his utmost to see whether reference to treatment of deafness could not be inserted in an earlier clause. He would not, however, give any pledge on the matter. On this understanding the amendment was withdrawn.

Disqualification of Practitioners

Lord LLEWELLIN moved an amendment to Clause 42 to make certain that a practitioner should have proper representation, that he could call witnesses and other evidence on his behalf, and that he could, if he wished, have the hearing in public. Lord READING, supporting, said that it ought to be made quite clear that the person appointed by the Minister to hear an appeal should possess legal qualifications capable of enabling him to take a proper judicial view of the evidence. The amendment was agreed to.

The LORD CHANCELLOR moved a new clause to ensure the preservation of associations of denominational hospitals. He agreed that such steps should be taken in the appointment of a resident surgeon, or the matron, but he could not extend it, as Lord Idlesleigh wished, to the staff. The Lord Chancellor said that for himself he would not care two little bits, if he were to be operated on, whether the surgeon possessed sound doctrines on the question of the justification of faith or not. He thought the hospital management committee could be depended on to see that the appointments they made conformed to the considerations of the clause.

Lord IDDESLEIGH said that so far as the Roman Catholic faith was concerned, they did not base their appointments on the faith of the candidates. He was a little more anxious about the staff, because there was the more important moral consideration a patient might have in regard to what a doctor believed about euthanasia. Lord READING said the matter intimately and deeply concerned the Jewish community, and he was grateful to the Lord Chancellor for this happy solution. The new clause was read a second time and added to the Bill.

An amendment by Lord LLEWELLIN to the Seventh Schedule to ensure that the chairman of the tribunal should be a practising barrister or solicitor of not less than ten years' standing was agreed to.

The Report stage was concluded.

Medical News

At the bicentennial celebrations of Princeton University honorary degrees were conferred on Sir Henry Dale, M.D., F.R.S., and Sir John Boyd Orr, M.D., F.R.S.

Prof. N. Hamilton Fairley, M.D., F.R.S., has been appointed honorary consulting physician in tropical medicine to the Ministry of Pensions.

The annual spring graduate course in ophthalmology and otolaryngology will be held at the Gill Memorial Eye, Ear and Throat Hospital, Roanoke, Virginia, U.S.A., on April 7-12.

A course of lectures on recent advances will be given in the House of the Royal College of Obstetricians and Gynaecologists (58, Queen Anne Street, W.) on Fridays, Nov. 1, 15, and 29, Dec. 13, and Jan. 10, at 5 p.m. Admission is free, by ticket, for which early application is necessary, to the secretary of the College. Applicants should state for which lectures tickets are required. Details will be published in the diary column of the *Supplement* for the appropriate weeks.

A conference of clergy, doctors, and nurses on collaboration in the service of the sick will be held in the library of the Royal National Hospital, Ventnor, on Monday, Nov. 4, beginning at 10.30 a.m.

Dr. H. Mandiwall will address a meeting of the Medical Group of the Royal Photographic Society on "Dental Photography" at the Society's house, 16, Princes Gate, S.W.7, at 6.30 p.m., on Thursday, Nov. 7. The address will be illustrated.

The Board of Control (Lunacy and Mental Deficiency) is returning from St. Annes on Sea to London and as from Monday, Nov. 11, its address will be 32, Rutland Gate, Knightsbridge, S.W.7. Telephone: Kensington 3456.

The Chelsea Clinical Society will hold a meeting at the South Kensington Hotel, 41, Queens Gate Terrace, S.W.7, on Tuesday, Nov. 12, at 6.30 for 7 p.m. A discussion on backache will be opened by Mr. B. H. Burns, Mr. Charles Read, and Dr. M. Bewley.

The British Council for Rehabilitation (32, Shaftesbury Avenue, London, W.) has arranged a short course on rehabilitation to take place in London from Nov. 12 to 14 inclusive. The course, which is one of a series to be held in various centres during the next twelve months, is intended to provide an opportunity to study the various phases of rehabilitation as one unified service. It is open to members of the medical profession and the ancillary medical services, to representatives of industry, social workers, and others specially interested in the subject.

At a meeting of the Medical Society of the L.C.C. Service to be held on Wednesday, Nov. 13, at 4.30 p.m., at the County Hall, Westminster Bridge, S.E., a discussion on "Penicillin in the Treatment of Disease" will be opened by Dr. J. Alston, Dr. B. Young and Mr. J. Jemson.

The annual meeting of Fellows and Members of the Royal College of Surgeons of England will be held at the College in Lincoln's Inn Fields, on Wednesday, Nov. 13, at 5.30 p.m., when a report from the Council will be laid before the meeting. Fellows and Members can obtain copies of the report on application to the Secretary, and a copy of the agenda will be issued on or after Nov. 8 to any Fellow or Member who applies for one.

The Royal Dental Hospital of London will hold its annual clinical "At Home" at 32, Leicester Square, on Saturday, Nov. 23, at 3 p.m. Cases of clinical interest illustrating the scope of the work undertaken at the hospital, especially the treatment of children and the young, are to be shown by members of the staff, and the various departments of the hospital and of the School of Dental Surgery will be open for inspection. On the same evening, at 7 for 7.30 p.m., the dinner of past and present students will be held at the Savoy Hotel, with Mr. E. D. D. Davis, F.R.C.S., in the chair.

A David Anderson-Berry Silver-Gilt Medal, together with a sum of money amounting to about £100, will be awarded during 1947 by the Royal Society of Edinburgh to the person who, in the opinion of the Council, has recently produced the best work on the therapeutic effect of x rays on human diseases. Applications for this prize are invited. They may be based on both published and unpublished work and should be accompanied by copies of the relevant papers. Applications must be in the hands of the general secretary, Royal Society of Edinburgh, 22, George Street, Edinburgh 2, not later than Jan. 31, 1947. It should be noted that an extension of the period allowed for the receipt of papers has been made.

The 50th anniversary of the foundation of the British Mycological Society was celebrated in London from Oct. 20 to 25. On Oct. 22, at the Royal Institution, the president (Dr. J. Ramsbottom) gave an address on "Mycology Then and Now," and papers on "Medical Mycology: Mould Products" were read, with Sir Alexander Fleming in the chair. The conference was continued on the following day. International delegates to the jubilee meeting were entertained by the British Council. The last item in the programme was a dinner in the refectory of the London School of Hygiene and Tropical Medicine.

Dr. Fred Grundy, barrister-at-law, medical officer of health for Luton, has been appointed chairman of the executive committee of the British Social Hygiene Council in the place of the late Dr. Otto May.

The branches of the General Register Office which were evacuated to the New Cumberland Hotel, Blackpool, at the beginning of the war returned to Somerset House on Sept. 30. While the Registrar-General and a small staff remained at Somerset House throughout the war, the general work of the Office has been carried out at Blackpool, the records of births, deaths, and marriages being arranged and indexed there and then sent to Somerset House to be kept in the vaults. The staff at Blackpool dealt also with all correspondence in connexion with the records. With the return of these evacuated branches the whole of the Office will be housed in London, except a part of the Statistical Branch and the whole of the Central National Registration Office, which remain at Southport.

EPIDEMIOLOGICAL NOTES

Paratyphoid in Sheffield

Our cases of paratyphoid fever were notified in the City of Sheffield on Wednesday, Oct. 16, and 4 more on Oct. 18. A letter was sent by the medical officer of health to general practitioners on that day, and a further 66 cases were notified Oct. 25.

The outbreak is due to paratyphoid B, and Dr. A. Felix reported that organisms isolated from 7 cases were all Phage type 2. The symptoms at onset in many cases were vague or misleading. Diagnosis was difficult until the recognition of rose spots and enlarged spleens in a few cases prompted the use of agglutination tests and stool culture. The majority of cases have shown malaise, fever, and gastro-intestinal disturbance, but in a few occipital headache with some stiffness of the neck have been the presenting symptoms. Splenic enlargement and rose spots have appeared in most cases. So far the disease has not been of a serious type and the incidence in the sexes is about equal. The age distribution up to Oct. 25 is interesting:

Sex	Age in Years					Total
	0-5	5-10	10-15	15-20	20 plus	
Male ..	15	11	4	1	1	32
Female ..	22	11	—	3	6	42
Totals ..	37	22	4	4	7	74

Up to the present the source of the infection has not been found. By Oct. 29 the number of cases involved had risen to 94.

Discussion of Table 1

In *England and Wales* there were further rises in the incidence of measles 224, and scarlet fever 27; the notifications of both diseases have increased by two-thirds in the past few weeks. A rise was also recorded for whooping-cough 51, following a continuous decline over seven weeks. There was a fall in the notifications of diphtheria 50 and of dysentery 19.

No local variations worthy of note were observed in the trends of scarlet fever or whooping-cough. Lancashire was mainly responsible for the fall in the incidence of diphtheria: this county the cases fell from 94 to 53. The increase in cases of measles was confined to a few counties, notably Durham 97, Middlesex 48, and Devonshire 48; the only decrease of any size was Lancashire 43. The returns for dysentery were the smallest for over five years.

In *Scotland* a decrease was recorded in the notifications of acute primary pneumonia 22, diphtheria 17, and scarlet fever 16. Increases were reported for whooping-cough 40 and cerebrospinal fever 9.

In *Eire* the notifications of diphtheria declined by 8 and of measles by 6. The incidence of diarrhoea and enteritis remained unchanged with 58 cases, of which 47 were recorded in Dublin C.B.

In *Northern Ireland* the returns for scarlet fever showed an increase of 22 and for diphtheria 5. Of the 54 cases of scarlet fever 23 were notified in Belfast C.B.; the remaining cases involved 15 areas.

Statistical Review for 1942

The publication of the Registrar-General's *Statistical Review for 1942* shows that the mortality in that year improved compared with the earlier war years. The death rate was 12.3 as against 13.5 and 14.4 in the two preceding years. Infant mortality recovered from the setback in 1941, when a rate of 60 was recorded, and fell to 51 per 1,000 live births, which qualified the lowest previously recorded rate. Maternal mortality (including abortion) was 2.02 per 1,000 total births. The death rate from diphtheria, 192 per million children under 15, was the lowest ever recorded.

Deaths from tuberculosis began to increase in 1940. The deaths during 1939-41 were 21,523, 23,470, and 23,339. In 1942 the number of deaths fell to 20,730, the lowest figure ever recorded. Cases, and fatal cases, of cerebrospinal fever rose in 1940 to about ten times the pre-war level. A small decrease was noted in 1941, and in 1942 the cases fell to 5,286 with 143 deaths, which were little more than half the corresponding totals of the previous year. There were 3,891 civilians killed in air-raids compared with 22,215 and 19,543 in 1940 and 1941. A decrease in the number of suicides was recorded.

Week Ending October 19

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,048, whooping-cough 375, diphtheria 278, measles 2,385, acute pneumonia 407, cerebrospinal fever 30, dysentery 57, acute poliomyelitis 20, paratyphoid 22, typhoid 5.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct. 12

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales, and Eire.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Atiology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Bathing after a Heavy Meal

Q.—Is it true that bathing in cold water soon after a heavy meal carries the risk of sudden death?

A.—This belief is widely held, and the Royal Life Saving Society's handbook warns readers "on no account to bathe shortly after a hearty meal"; however, it does not describe the consequences of transgression. Cramp, which is a painful muscular spasm, cannot of itself be fatal, though it is possible that a bather so afflicted might drown. Even this is uncertain, for many of the authorities on swimming regard the dangers of cramp as greatly exaggerated. Thus, Dr. Hunter Barron, himself both a noted swimmer and a frequent sufferer from cramp, wrote in 1886 that cramp seldom killed and most of the alleged instances were examples of heart failure. The cause of cramp in swimmers is itself debated. Winmann, in *Colymbetes sive de Arie Natandi*, published in 1541 and the first known book on the subject, attributed it to cold. Although this is still currently believed, recent authors regard it as mere superstition. Cramp is more rationally presumed to be a symptom of muscular fatigue, although the blood supply to the muscle and a disturbed salt metabolism are of importance in some cases. That cramp occurs more readily after a heavy meal than at other times is unproved, although it would be easy to give physiological reasons for its doing so. Inability to move the limbs would presumably be a symptom of cramp.

Medico-legal authorities speak of the possibility of shock from the sudden application of cold to the skin causing reflex stoppage of the heart. Crookshank (*Trans. med. leg. Soc.*, 1909-10, 7, 11) believed that one-third of the fatalities apparently due to drowning were the consequence of this reflex inhibition. There is again no evidence that such an occurrence is more common after a meal. In short, there is evidence, albeit unsatisfactory, that very occasionally immersion in cold water may cause sudden death, but none that this rare accident is more common after a heavy meal. It is easy to see that such a tradition could arise from occasional instances of coronary thrombosis, to which both sudden exertion and a large meal are recognized predisposing factors.

Trichomonas Vaginalis and Streptococci

Q.—Can you give me any information about a non-haemolytic streptococcus which is said to be found in conjunction with *Trichomonas vaginalis*?

A.—This question probably refers to the claim by Hibbert (*Amer. J. Obstet. Gynec.*, 1933, 25, 465) that *Trichomonas vaginalis* can produce vaginitis only when there is present in the vagina a non-haemolytic streptococcus the characters of which are not specifically defined. In support of his claim Hibbert maintained that *Trichomonas vaginalis* may be present in the vagina unassociated with evidence of infection; that in most cases of trichomonas vaginitis a non-haemolytic streptococcus is present, often as the predominating organism; that cases of vaginitis may occur in which the non-haemolytic streptococcus is apparently the causative organism; and that treatment with a broth filtrate of the organism produced cure or amelioration of the mixed infection with disappearance or reduction in the numbers of non-haemolytic streptococci but not of the trichomonas. In addition, three volunteer patients in whose genital tract *Trichomonas vaginalis* was implanted

without producing clinical infection developed vaginitis a culture of the non-haemolytic streptococcus was added, claims have not apparently been substantiated, and in the discussion that followed Hibbert's paper there was much comment on his findings.

Notification of Gastro-intestinal Diseases

Q.—Please define "dysentery" and "diarrhoea and sickness syndrome (gastro-enteritis)" in relation to notification (a) the Public Health Regulations and (b) under the Food and Drugs Act.

A.—In the Public Health (Pneumonia, Malaria, Dysentery, 1919, and the Public Health (Infectious Diseases) Regulations, 1927 (S.R. & O., 1927, No. 1004), it is stated "dysentery includes amoebic and bacillary dysentery." There is no "clinical" definition or description of the disease. The absence of clinical description is common to all the notified infectious diseases, with the exception of puerperal pyrexia.

By the Food and Drugs Act, 1938, Section 17, it is the duty of a registered practitioner to notify the medical officer of health of the district of any patient who is suffering or suspected of suffering from food-poisoning. In the Act "food" is defined as "any article used for food or drink for human consumption other than drugs or water, and includes (a) any substance intended for use in the composition of or preparation of food; (b) any flavouring matter or condiment; (c) any thing intended for use as food. Food-poisoning means poisoning caused by the partaking of any substance which comes under the given definition of food."

The "diarrhoea and sickness syndrome (gastro-enteritis)" which has many synonyms—is not generally notifiable, but so in some areas by local order with variations in the age limit. In one area it may be notifiable only in children up to 2 years old; in another area the age limit may be 5 or even 10. If, therefore, a child is found to be suffering from diarrhoea and vomiting in an area where gastro-enteritis is notifiable it is possible to notify the case under the Public Health (Infectious Diseases) Regulations if dysentery is suspected; under the Food and Drugs Act if food poisoning is suspected; and under the local order if gastro-enteritis is suspected. The final decision would rest on the history, and on the extent and nature of the clinical and bacteriological evidence.

Radiotherapy of Hodgkin's Disease

Q.—What is the prognosis in cases of Hodgkin's disease treated by radiotherapy?

A.—Radiotherapy is not a cure for Hodgkin's disease. It will abolish local enlargement of lymph nodes, but subsequently other groups are affected. Finally the patient reaches a stage of cachexia in which there is little response to further irradiation. It is doubtful whether life is prolonged by this treatment, although symptoms are temporarily relieved. Few patients survive more than four years.

Adrenaline Secretion and Asthma

Q.—It is commonly stated that psychological imbalance is one of the most important aetiological factors in spasmodic bronchial asthma, and that an attack is often determined by an acute increase of apprehension or anxiety. In such an event one might expect the endogenous secretion of adrenaline to be correspondingly increased, and this would go far to counteract any tendency to bronchial spasm. Is there any evidence that the production of adrenaline is deficient in asthmatics, or that their over-anxious temperament is responsible for a sub-clinical state of adrenal exhaustion? If not, how may this apparent paradox be explained?

A.—No evidence has been found that the production of adrenaline is deficient in asthma, and the absence of other signs of lessened sympathetic activity supports the view that there is probably no type of asthma caused by a deficiency of natural adrenaline secretion. Also there are no pathological changes in the adrenals in asthmatics. The paradox referred to in the question exists only if the psychological factors that precipitate asthma lead to an increased output of adrenaline. In anxiety states and neuroses generally it cannot be said that an increased secretion takes place, and, while there is possibly an enhanced sensitivity to adrenaline in some cases, this is not to be taken as indicative of any well-defined humoral change.

It is possible that the psychological factors which precipitate asthma may in fact give rise to a parasympathetic overaction and thus facilitate the onset of an attack. It has recently been suggested that the emotions of anger and elation are associated with parasympathetic excitation, and that of fear with sympathetic excitation. In this last connexion it has been noticed during conditions of prolonged fear, as in air raids, that thymatic subjects have not had attacks in circumstances here they might have expected them. Here it is possible that increased adrenaline production has prevented the onset of bronchial spasm in the manner suggested in the question; it seems highly probable that, in so far as psychological factors play a part in asthma generally, they do so by increasing the parasympathetic sensitivity to a greater extent than the sympathetic sensitivity of the bronchial musculature.

Benzyl Benzoate Dermatitis

Q.—Can you suggest treatment for a skin affection apparently due to prolonged application of benzyl benzoate? The patient suffers a severe irritation when he gets warm in bed, but has no discomfort during the daytime.

A.—It is assumed that the patient referred to has developed chronic dermatitis from the prolonged use of benzyl benzoate emulsion for scabies, and is not suffering from an independent itching dermatosis. The dermatitis is thus exogenous and would respond to rest, avoidance of baths, and simple greasy applications, such as oily calamine lotion or boric-zinc ointment to which a small amount of arachis oil has been added. Sedatives given at night are helpful, and whole-blood injections, if the skin permits, assist in allaying itching.

Pituitary Extract in Obesity

Q.—What is the present-day teaching as to the oral administration of whole-gland pituitary extract? In treating obesity how much pituitary whole gland administered?

A.—There is no experimental or clinical evidence in favour of the view that whole-gland pituitary extract given orally exercises a hormonal influence in man or other mammals. Some clinicians still hold the view that it augments the effect of thyroid in cases of obesity, and others prescribe pituitary gland because the patient has already received thyroid alone without appreciable benefit. If so administered, tablets of 1 or 2 grains (65 or 130 mg.) of pituitary whole gland or anterior pituitary gland (dried extract) are often prescribed.

Quite apart from the probable ineffectiveness of pituitary gland by mouth, it is doubtful if any available pituitary hormone given by injection has any influence on obesity. Some years ago Collip described an extract of pituitary gland which increased the metabolic rate and lowered the respiratory quotient, indicating metabolism of fat, and some initial clinical work with this hormone was published. However, nothing further has been heard of this latter work for several years, and it therefore seems doubtful whether any positive results have been sustained.

Leuco-erythroblastic Anaemia

Q.—Should leuco-erythroblastic anaemia be differentiated by reason of the stimulating or irritating effect of certain lesions on the bone marrow or by the blood picture? If by the blood picture, should not familial acholuric jaundice, von Jaksch's syndrome, and the erythroblastic anaemias also be considered leuco-erythroblastic?

A.—It is important when discussing leuco-erythroblastic anaemia to agree upon a definition of the term. It refers not to a "disease" but to certain changes in the peripheral blood. These changes are: anaemia, which varies in degree but may be insignificant, with erythrocytes usually of normal size; reticulocytosis; the presence of nucleated red blood cells; a total leucocyte count ranging from 2,500 to 30,000 per c.mm. or even higher; and a characteristic alteration in the differential leucocyte count. This alteration is not simply "the presence of immature cells" but a "shift to the left" of the granular series, with a regular gradation decreasing from large numbers of fully segmented neutrophils, through regularly diminishing proportions of cells of all grades of immaturity, to a small percentage of myeloblasts. In some cases the "shift" does not extend as far as the myeloblast. Defined in this manner

a leuco-erythroblastic anaemia may accompany a large variety of disease processes, from carcinomatosis of the bone marrow to acute haemolytic anaemia.

This is equivalent to saying that, as leuco-erythroblastic anaemia is a symptomatic blood change and not a "disease," the label should be applied to those cases in which the blood change exists, irrespective of the underlying pathological process. It is true that there is a tendency to limit the use of the term to cases in which this blood picture is associated with carcinomatosis of the bone marrow, myelosclerosis, and related disorders. It is also true that in these affections leucopenia and thrombocytopenia are common, while in others leucocytosis is the rule, but the restriction is illogical. The question illustrates the pitfalls of haematological nomenclature and the need "to define one's terms."

Corneal Herpes

Q.—What are the earliest signs by which one can recognize corneal herpes, and what is the treatment? Does it cause corneal scarring?

A.—Corneal herpes is a rather indefinite term. Presumably it refers to corneal lesions of the herpes simplex or herpes zoster type and not to mere vesicle or bulla formation. The difficulty arises from the fact that recognizable vesicles suggestive of herpes simplex or zoster are rare in the cornea in these affections, while vesicle formation which has nothing to do with these affections is not uncommon. Taking the aetiological rather than the morphological sense of the question, it is again difficult to be unequivocal, for there are a whole series of corneal lesions which are regarded as herpetic in origin, the commonest being dendritic ulcer, superficial punctate keratitis, disciform keratitis, and some varieties of keratitis profunda. In all these affections diminution or loss of corneal sensation is the most striking early feature, and this is most marked in the corneal complications seen in herpes ophthalmicus. Generally an associated herpetic lesion is absent, and the assumption that these corneal lesions are herpetic in origin is based on rather inconclusive laboratory findings.

The treatment of corneal herpes depends largely on the type of corneal lesion. In all cases two drops of atropine 1% are instilled three times a day, and the eye protected either by dark glasses or by a bandage. In dendritic ulcer the denuded epithelium may be touched with pure carbolic or a 30% solution of sodium sulphacetamide, and such treatment may have to be repeated frequently, even daily. In superficial punctate keratitis no local medication, apart from the instillation of atropine, is of any value, and this probably also applies to disciform keratitis and to keratitis profunda. Immune serum has been suggested for superficial punctate keratitis, but results are conflicting. There is no treatment known to abort an attack of corneal herpes, and the prognosis depends on the type of lesion. In superficial punctate keratitis recovery is the rule after six to twelve weeks, and dendritic ulcers run almost as protracted a course. In both conditions corneal scarring is unusual, but dendritic ulcers tend to recur. Occasionally disciform keratitis clears remarkably well. More frequently both disciform keratitis and keratitis profunda leave extensive and marked corneal opacities.

Air Travel for a Baby

Q.—Is there any contraindication to a journey by air to New Zealand for an infant of 7 weeks? Should the baby be protected by inoculation against yellow fever?

A.—A full-term normal infant would probably tolerate the flight satisfactorily, but it would be essential to provide an infant's oxygen tent (which can be improvised from an infant's gas mask) in case of cyanosis, or in the event of any part of the flight being at an altitude of over 7,000 ft. (2,100 m.). In the case of a premature baby or of one who has shown evidence of atelectasis or intracranial haemorrhage the journey by air would be contraindicated. The risk of failure of the heat-control system in the plane should also be considered. Under these circumstances there is a very great drop in temperature if the plane is travelling at 10,000 ft. (3,000 m.) or higher.

Infants and small children stand protective inoculations against yellow fever well, and do not appear to be upset by these injections. Inoculation is compulsory, as in adults travelling by air.

LETTERS, NOTES, ETC.

Amoebic Dysentery

Lieut.-Col. C. CROPPER (Keighley) writes: With reference to the question and answer on amoebic dysentery (Aug. 10, p. 215) I should like to make two constructive comments. I have found that in very many patients phenobarbitone by no means prevents the emetic effects of emetine bismuth iodide. The simple precaution, however, of "washing down" the capsule with an iced drink, so that it reaches the duodenum before it melts, works admirably. The capsule of E.B.I. must not be taken until four hours after the last meal of the day. This method renders phenobarbitone quite unnecessary. Secondly, retention enemata will be neither effective nor tolerable without close attention to the details of technique. I have found "bowel washouts" ill-advised, as they tend to bring down into the lower bowel the contents of the ileum, thereby defeating the object of the manoeuvre and incidentally causing an unpleasant gripping pain. A bicarbonate enema of the smallest effective volume is in my experience, both as patient and physician, the maximum preparation called for; at least four hours thereafter the chiniofon is introduced. The evacuant enema is given in the morning at any time that suits the nursing staff, and the retention enema at any time in the afternoon; and the latter is usually retained indefinitely—i.e., until the next morning's evacuant enema. If not, 1/2-1 dr. (1.8-3.5 ml.) of tinct. opii may be added to subsequent retention enemata. Restriction of meals is unnecessary. On the above lines the desired result is achieved—viz., the maintenance of the chiniofon in contact with the ulcerated mucosa in the maximum concentration for the maximum time. It is essential that treatment be carefully supervised, with deliberate study of the individual patient's reactions; otherwise all that is achieved is the subjection of the patient to a prolonged and trying ordeal. My own impression is that the best results are given by a combination of chiniofon enemata with oral diodoquin, but many cases still defeat all attempts at cure.

Milk "Priority"

Dr. G. L. DAVIES (Hove) writes: The daily papers show that the public is again becoming restive about milk priorities, and rightly so. Doctors, with some reason, had hoped that by this time the irksome task of deciding who in every case was entitled to extra milk would have been a thing of the past. However, as the food situation continues to deteriorate, people will look round for some ailment which they may put forward to entitle them to extra milk, and by now they have got to know the ropes. Holders of priority milk certificates—and some have now held them for a matter of years—are as a whole a selfish race of people, and any determined suggestion on the part of a doctor that they are now better and should give up their claim to priority only produces some exhibition of rudeness and a mild fracas in the surgery. Some have had certificates on the strength of symptoms suggestive of peptic ulcer, and they resolutely refuse to go and have their symptoms verified or disproved by x rays, usually contriving to find some excuse to delay this inconvenient matter. It is now time that the last word in this business was taken out of the hands of the family doctor and entrusted, may one suggest, in every large centre of population, to a small panel of medical men and women who are, preferably, not in general practice. The family doctor should be asked to submit a few written details about each case and add his private opinion, and the final decision should rest with the referees. Meetings at which applications for extra milk (i.e. for those cases which present some difficulty) are considered might take place once a month, so as not to take up too much of the time of the doctors concerned. Adequate payment per session should be made to each doctor by the Ministry of Food. To some all this will appear like trying to make a mountain out of a molehill, the sort of small campaign which a Prussian general once said wasn't worth the bones of a single grenadier. As a doctor in a numerous working-class practice, striving each day to cope with ill-defined ailments which are unresponsive to ordinary medical treatment, one is forced to the conclusion that the human body is beginning to rebel against synthetic vitamins, and little enough of those. Until the war ended we heard much about the writing on the wall. What we hear in our surgeries and what our wives hear in queues is writ far larger than any fictitious writing on the wall. Let our rulers ignore it at their peril. [See also p. 661 on this subject.]

Scorpion Sting

Dr. B. V. RAMASWAMY (Bangalore, South India) writes: In the *Indian Medical Gazette* of Nov., 1939, and Jan., 1940, there were two small notes about scorpion sting. (i) "Fresh leaves of *Acalypha indica* when rubbed well at the site of the sting relieve the pain and cure the patient in about five minutes." (ii) "A few whiffs of chloroform inhalation almost immediately cure the pain. About 2 dr. (7 ml.) may suffice for nearly 50 persons." Since then I have tried chloroform inhalations for scorpion stings with great success. There are two types of pain experienced by such patients. One is a local, throbbing pain at the site of the sting, and the other a rapidly spreading, shooting pain. If the patient gets the treatment

within 5-10 minutes of the sting both the pains disappear in about 5 minutes. In cases where the treatment is begun after some time—more than half an hour after the sting—the shooting pain appears in 5 minutes, but the local pain persists though in a lesser degree. To eliminate that pain I usually inject a local anaesthetic all round the site of the sting, which gives complete relief. *Treatment*.—A few drops of anaesthetic chloroform are sprinkled on a small piece of cotton-wool and held near the patient's nostrils. It is then asked to inhale deeply a number of times. Most patients if treated early find relief of pain in 2-5 minutes. I would very much like others to try this simple treatment and report their experience. I would also like to know how chloroform neutralizes the toxins of the scorpion.

Varicose Veins

Mr. R. ROWDEN FOOTE (London, W.) writes: This all too common condition has received scant notice from the statisticians in the past. A few months ago inquiry at the Ministry of Health produced the answer that no figures were available. In fact they had no knowledge as to how many of the population suffered from the condition or how much invalidism was caused by varices and the complications. My attention has recently been drawn to morbid figures in a Ministry of Health publication *On the State of Public Health during six years of War (1946)* which seem to give confirmation to the unproven prevalence of this disease in the community. I need only quote a few statements from this book taken at random in order to bring out my points, the figures being quoted per 1,000 of the admissions to E.M.S. hospitals during certain of the war years. The total number of diseases of veins in males treated as in-patients in E.M.S. hospitals in 1945 shows the astonishing figure of 86 per 1,000 in England and per 1,000 in Scotland; in 1943 this figure was reduced to 75, 1,000. This figure, reaching nearly 10% of hospital admissions only exceeded by one other group of patients—those suffering from diseases of the skin and cellular tissues. Under the heading "Periods of Disablement for Men from the ages of 15 to admitted to E.M.S. hospitals from the Services during 1942-1943" we find that out of approximately 2,000 cases of varicose veins

	213 are incapacitated for	10 days
654 "	"	" 14 "
122 "	"	" 21 "
227 "	"	" 28 "
198 "	"	" 42 "
313 "	"	" 56 "
110 "	"	" 91 "
6 "	"	" 182 "

In other words varices, forming 10% of all hospital admissions, and being the second largest group of complaints treated by the E.M.S., present a very high figure as far as duration of incapacity is concerned. A further point brought out by these statistics is that in the diseases of veins men's rates were much higher than those for women. It has been said that statistics can "prove anything, even the truth"; but even so, here is serious food for thought. Why is it that the humble varix receives so little consideration in this country? In many hospitals it still serves as practice for the student or recently qualified surgeon. Varicose ulcers, which should become rare with adequate treatment, still tend to multiply and to be relegated to the dark corners of our hospitals. Phlebitis is treated by immobility and hypostatic eczema by unguents. The "set up" of the average varicose department is reminiscent of the state in which many fracture clinics functioned in my early student days. It is to be hoped that in the process of time this prevalent disease may receive the same expert care as is now being given in our orthopaedic departments. One hundred years ago, standing by the bedside of a sufferer from varicose ulceration, Sir Benjamin Brodie said to his students: "Here is a case of a very distressing nature, and such an one as may meet you at every turn of your practice; and your reputation in early life will depend more upon understanding a case of this kind than on your knowledge of one of more rare occurrence. . . ." (*Lectures on Pathology and Surgery*, 1846.) What has been done to put the treatment and care of the varicose patient into any better state than it was when these words were spoken a century ago?

Correction

Prof. S. LEITIS, of Moscow, wishes to correct two sentences in the translation of his article "The Importance of Autoregulation in Nitrogen Metabolism" published in the *Journal* of June 8. On p. 875, column 2, line 16 from the end the words "increase in the nitrogen metabolism" should read "increase in the nitrogen content." On p. 376, line 9 from the top, the following words should be added: "after introduction of protein or nitrogen metabolites."

Allen & Hanburys, Ltd., announce that from Nov. 4 they are adopting a 5-day working week. The offices and warehouses at Bethnal Green will be closed on Saturday mornings, but their West End branch at 7, Vere Street, W.1, will be open to deal with orders for urgent medicines.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 2 1946

ANNUAL PANEL CONFERENCE

THURSDAY, OCTOBER 24, 1946

ACCEPTANCE OF MINISTER'S OFFER COMING DISCUSSIONS ON CAPITATION FEE

The Annual Conference of representatives of Local Medical and Panel Committees was held in the Great Hall, British Medical Association House, London, on Thursday, Oct. 24. Dr. J. A. BROWN (Birmingham), who in the course of the proceedings was, without a contest, elected Chairman of the Conference for another year, presided, and was supported by Dr. E. A. Gregg, Chairman of the Insurance Acts Committee, Dr. Charles Hill, Secretary of the Association, and Dr. J. W. Bone, Treasurer of the National Insurance Defence Trust. The agenda and the expected length of the Conference were modified as a result of the Minister's new offer fully to apply the Spens Report to the current capitation fee and inviting the Insurance Acts Committee to enter into discussions on the report forthwith; several amendments were withdrawn in view of the altered situation, but the discussions on the capitation fee, the attitude of the Minister, and the possibility of further contest before a satisfactory outcome is reached occupied fully half the time of the Conference. There was a full attendance of representatives from all parts of Great Britain.

Application of the Spens Report

Dr. E. A. GREGG, who was greeted with cheers, proposed as a recommendation from the Insurance Acts Committee:

That the Minister's offer, in the letter of Oct. 18 from Sir William Douglas, be accepted.

[The letter of Oct. 18 from the Permanent Secretary of the Ministry of Health appeared in the *Supplement* of last week (p. 103) and read as follows: "The Minister is willing fully to apply the Spens Report to the current capitation fee from Jan. 1, 1946, the increase of 2s. being regarded as a payment on account. To this end he invites the Insurance Acts Committee to enter into discussions on the Report forthwith, with special reference to the current capitation fee. The discussions will be conducted expeditiously."]

In presenting this recommendation Dr. Gregg said that it was unnecessary for him to explain that the Conference met that day under conditions considerably different from those anticipated when the agenda were prepared. It was unnecessary for him to enter upon any lengthy review of the history—the very unsatisfactory history—of the capitation fee. He would go back only to the days when Mr. Ernest Brown was Minister of Health. The I.A.C. had discussions with Mr. Brown, and eventually succeeded in convincing him that the conditions concerning the capitation fee were completely unsatisfactory. Mr. Brown agreed, and stated plainly that there was only one way of dealing with the question, namely, to open discussion "from the ground up" and to determine what would be reasonable payment for doctors doing health insurance work. That undertaking was given by Mr. Brown, and as soon as circumstances warranted they pressed for the fulfilment of his promise. In due time the Spens Committee was appointed and set about the task of investigating the remuneration of practitioners engaged in a public service. When the Spens Committee Report was issued the Insurance Acts Committee approached the Minister and asked that its recommendations be implemented. The Minister met them with the requirement that in such discussions over the Spens Report consideration must also be given to the remuneration in another service which

had not yet been passed into law, which had not been approved by the medical profession, and in which the profession had not signified its intention of taking part. It was pointed out to the Minister that the I.A.C. represented the insurance practitioners of the country only and that it was concerned with obtaining a satisfactory remuneration for doctors engaged in that service and with nothing else. The Minister, however, still insisted on his conditions that the two things—namely, the current insurance remuneration and the remuneration in any future service—should be discussed together. Finally they arrived at the state of affairs expressed in a motion which it had been intended should be brought forward by the I.A.C. and which would have authorized that committee at its discretion to put in the resignations of insurance practitioners unless the Minister was willing fully to apply the Spens Report to the current capitation fee with effect at least from Jan. 1, 1946, or failing agreement, to refer to the Spens Committee or a representative section of it, or other agreed independent body, the interpretation of the Spens Report in relation to the current fee. The line the I.A.C. had taken had been endorsed by an overwhelming majority of Panel Committees and their constituents throughout the country.

Dr. Gregg thought that there must have been echoes of these events in Whitehall because he could not otherwise explain the invitation received from the Ministry that representatives of the Insurance Acts Committee should go there again—an invitation accompanied by the remark that there had been some misunderstanding. He was prepared to believe that there had been a misunderstanding on the part of the Ministry concerning the real temper of insurance practitioners. However, four representatives of the committee, together with the Secretary, attended at the Ministry and the matter was reopened, and after much discussion they arrived at a form of words which expressed in general terms the opinions of those participating. That form of words—which did not wholly satisfy the representatives—was brought back to a full meeting of the committee, and, after discussion, Sir William Douglas was invited to attend and came at very short notice. It was explained to him that the committee felt grave misgivings concerning one phrase in the proposed procedure:

"Discussions . . . on the factors common both to current insurance remuneration and to remuneration in any future service."

After further discussion the procedure set out in Sir William Douglas's later letter of Oct. 18, already quoted, was accepted by the I.A.C. as a recommendation to the Conference. There might be arguments about this communication, but the committee believed that a sufficiently precise undertaking had been given to justify them in entering upon the discussions. They had in fact enough here to enable them to "get on with the job." He therefore asked for the authority of the Conference to accept the Minister's offer as stated in the letter of Oct. 18.

Talk of "Victory"

Dr. R. W. COCKSHUT (Hendon) said that a great victory had been won by insurance practitioners and Mr. Bevan had sustained a defeat. The victory was due without doubt to the fact that the practitioners had stood solid behind their representatives. He hoped in future they would talk less about what happened in 1911 and more about what happened in 1946. He knew that there were people who deprecated any talk of victory, but the fact ought to be put on record that

Mr. Bevan had in effect said to the profession, "My patience is exhausted. Here is 2s. Take it or leave it," and the profession had left it. Mr. Bevan had now agreed to enter upon further discussions on the basis which the I.A.C. had laid down. This victory had been won by the ordinary insurance doctors, and, moreover, it was a victory for the British Medical Association.

Dr. GORDON WARD (Kent) said that he was not going to reply to Dr. Cockshut but he wanted a little more information to take back to his own Panel Committee. The exact form of words which the I.A.C. had refused to accept might reveal the Minister's mind. He also desired to know whether the committee had in view any sort of figure to which they were prepared to stick in the forthcoming negotiations. It was inaccurate to say that the Spens Report promised 15s. if 40,000,000 people were in the service. He would like the committee to say, "Fifteen shillings or we go back to a special Conference." The sum of 15s. might be 15s. in the new service, and that would be, presumably, less the basic salary, if any, less payments to practitioners who were taking assistants, and less anything else the Minister cared to include. The profession had obtained an advantageous position and he was not so churlish as to withhold praise from the Insurance Acts Committee, but this was not a victory yet.

Dr. J. A. IRELAND (Shrewsbury) said that he too did not look upon this as victory as yet. It was misleading to talk of victory. Loose statements had been made in the press that the doctors were going to have a capitation fee of 15s. given to them by the Minister. There was no foundation for this whatsoever. The implementation of the Spens Committee Report depended upon para. 19 of that report, in which it was stated that the 15s. referred to a 100% service for the whole population, and that was taken on the basis of the 1939 figures, to which betterment must be added. There was one thing of vital importance, namely, that the proposed discussion now to be opened should not be long delayed. The Minister had often said to representatives of the profession, "I know that you are divided." There was very little division apparent in the present temper of the profession, as shown by the willingness of between 95 and 100% of practitioners to place their resignations in the hands of the committee—a unity never attained before. But the discussions should be speeded up. In other important trade disputes matters were settled often within a week. Although the Minister's undertaking must be accepted, one month should be ample time in which to complete the discussions.

Dr. W. JOPE (Lanark) agreed that a word of caution was necessary. He did not like to hear talk of victory when the battle had only just started. It was true that a break-through had been made, but victory had by no means been won. He hoped that before the Conference broke up the I.A.C. would be given some power to deal with any situation which might develop in the immediate future. He added that the present favourable position had been reached notwithstanding a very ill-timed communication by a body other than the B.M.A.

Dr. GREGG said that for his part he did not think there was any reason why they should not have the terms of the communication received originally from the Minister with which the committee was not satisfied. They were:

"Discussions to be begun immediately with the Insurance Acts Committee on the factors common both to current insurance remuneration and to remuneration in any future service so as to apply the Spens Committee report to insurance remuneration. Every effort will be made to complete the negotiations expeditiously. The capitation fee decided upon will be paid retrospectively to Jan. 1, 1946—the 2s. increase being a payment on account."

That was the communication which the committee considered at its meeting a week ago and with which it was not satisfied. On the question of the 15s. which had been mentioned, such a figure did not exist. They were faced with a position in which they had a report from a responsible body stating that practitioners' incomes were too low before the war. They had to relate that report to the payment received under National Health Insurance. There was subsequently brought into insurance in 1942 a class of people who were able and accustomed to pay fees considerably higher than the fees of the lower-paid industrial class, namely, those non-manual workers whose incomes reached £420. They had also to remember that there was a betterment figure to allow for the diminished value

of money. With those points before them they had to put out from the Spens Report what figure ought to be paid 15s. mentioned in the Spens Report was related to another of circumstances altogether.

He agreed that the term "victory" might be open to some criticism, but, after all, it was a victory when it was a responsible Minister, who at first had refused to talk in the way they wanted to talk, being obliged to turn and say that he was willing to adopt a different proposal. He knew no other name for what had been achieved victory. But it was a victory that had to be devoted to Alamein was not the winning of the war but it was the turning point, and this was their Alamein. (Cheers.) He agreed with Dr. Ireland that speed was essential, and he was prepared to move a later resolution to give a certain power to the committee to exercise pressure in the way of getting up as much speed as possible.

The motion accepting the Minister's offer as contained in the letter of Oct. 18 was put to the Conference and unanimously.

A rider was moved by Dr. W. LIVINGSTONE (Stoke-on-Trent) to the effect that in accepting the Minister's invitation they should make clear to him that his phrase "with special reference to the current capitation fee" must not be construed as suggesting that the negotiators had any mandate in matters pertaining to the future national health service was agreed to.

Dr. GREGG said that he did not think that the Conference need have any doubt regarding the firm position which the I.A.C. would take up with the Minister. They had on many times that they had no intention of being forced into a position of discussing anything in relation to some future

Expeditious Application

Dr. GREGG further moved:

That this Conference authorizes the Insurance Acts Committee to take any necessary action to secure full and expeditious application of the Spens Committee Report to the current capitation fee, and to include, if the Committee considers it necessary, the collection and use of the resignations of insurance practitioners.

It was essential that the Minister should realize that the committee had behind it a firmly united profession. The resolution was carried unanimously.

A Solid Profession

The SECRETARY (Dr. Charles Hill) announced the results of voting on the Insurance Acts Committee's recommendation to insurance practitioners to place their resignations in the hands of the committee unless the Minister was willing fully to apply the Spens Report to the current capitation fee. He said that up to the previous day reports had been received from 146 Panel Committees. In 63 areas the voting was unanimously in favour of the I.A.C. recommendation; in 29 areas there was one dissident; in 14 areas 2 dissidents; and in 40 areas more than 2, though in most of these areas the number of dissidents did not exceed 5. Over 95% had expressed their willingness to resign if called upon.

Time Limit for Negotiations

Dr. PARKER (Swansea) moved that there should be a time limit to negotiation and suggested Jan. 1, 1947, thus leaving no loophole for long-drawn-out discussions. Dr. J. A. IRELAND moved to substitute Dec. 1, 1946. He thought that five weeks from the termination of the present Conference was ample time. Dr. A. V. RUSSELL (Wolverhampton) and Dr. W. WOOLLEY (Bristol) spoke to the same effect. Dr. W. D. STEEL (Worcester) thought that with every desire to get these discussions through expeditiously they ought to be careful before fixing a definite date. This matter must be looked at from a practical point of view. After all, to say that the discussions must be concluded by Dec. 1 left them with only five weeks.

Dr. GREGG said that the Insurance Acts Committee was anxious to see that this matter went through quickly and by the resolution just passed the Conference had given the committee power to expedite it. But the question of betterment might involve considerable investigations, and it might be necessary

ry to call in the evidence of people who were specialists in at line. He asked that the committee should not be bound by any actual date. Moreover, they might remember that whatever fee was ultimately determined it would be back-dated to Jan. 1 of the present year.

The motions to impose a time limit either of Dec. 1, 1946, or Jan. 1, 1947, were lost by an overwhelming majority.

In reply to a question the SECRETARY read from the first schedule of the Regulations:

"A practitioner is entitled at any time to give notice to the Insurance Committee that he desires to withdraw his name from the Medical List and his name shall be removed therefrom at the expiration of three months from the date of such notice or of such shorter period as the Committee may agree."

to this there was a proviso:

"If such notice is given by the practitioner within one month after the issue to him by the Committee of a notice informing him of the proposed alteration in the terms of his service, including any amendment of the allocation or distribution scheme, two months shall be substituted for three months as a maximum period for which he may be required to continue to undertake insurance practice."

In the position contemplated by this notice the period would be three months from the day the notice had been put in.

National or Regional Action

Dr. F. C. COZENS (Kent) moved that should it be necessary or any withdrawal of service it should be by way of national and not regional action. National action would show the unanimity of the whole body of practitioners. Dr. BREACH (Kent) said that his constituency was somewhat concerned as to how withdrawals would operate along the margin of regions if the doctors in one region were practising normally and those in the adjacent regions were withdrawing. Dr. S. WAND (Birmingham) hoped the Conference would not pass any resolution concerning a particular method of carrying out a fight should it be necessary. They could not discuss the machinery of carrying out a fight in a Conference of that kind, and he suggested that this resolution and others of like tenor should be referred to the I.A.C. Dr. GREGG said that regional withdrawal had never been seriously pursued. There had not been any suggestion that withdrawal of service should be other than national. It was agreed to refer this motion to the committee.

Public Relations

Dr. E. M. TUSTIN (Somerset) moved that, if the necessity for direct action arose, notices explaining briefly the reasons for the action of the doctors be sent to all insurance practitioners for exhibition in their waiting-rooms. Dr. C. F. R. KILLICK (Somerset), supporting this suggestion, said it was important that the outstanding facts of the matter should be published. Dr. GREGG accepted this suggestion on behalf of the I.A.C.

Dr. W. WOOLLEY (Bristol) moved:

That in the event of it being necessary to use insurance practitioners' resignations, the Insurance Acts Committee be asked to take the most energetic action to ensure that the public is fully informed of the necessity for this action; that particularly the methods of the Ministry of Health in its dealings with the medical profession over a period of years be made known in a manner easily understandable by everyone; and that when the resignation forms were sent to practitioners, the accompanying notice will contain the notice that this will be done.

The public, he said, should be informed that this was not a mere political battle. They were not just against this Minister or this Government. Points to be emphasized were the 1941 story concerning the "cash in the pool," the unilateral scrapping of the agreement and the raising of the income limit to £420, and the questionable evidence offered at the Court of Inquiry in 1937.

Dr. D. F. HUTCHINSON (Middlesex) strongly supported the motion. Dr. A. C. DAWES (Smethwick) urged that the Public Relations Committee of the B.M.A. should undertake a special press campaign to bring the doctors' case before the public.

Dr. H. H. D. SUTHERLAND (London) said that the section of the I.A.C.'s report (*Supplement*, Sept. 28) headed "Insurance Capitation Fee" had the essentials of a "best seller," and with

an appropriate introduction might be offered to the public as a statement of their case.

Dr. GREGG said that they were well represented on the Public Relations Committee of the B.M.A. in Dr. Dain, its chairman. There were many factors to be taken into consideration in adjusting the figures, but it was abundantly clear that insurance practitioners in general were solidly behind them. Dr. M. J. MURRAY (Dundee) said that he and his partner were on the panel in three insurance areas. In their principal area they both voted for the I.A.C. recommendation, but in the other two areas neither of them voted, thus accounting for four of the "missing." Dr. WOOLLEY's motion was carried.

Dr. J. MCCREA (Berkshire) proposed a motion deploring the fact that the publicity given to the matter had failed to make it clear that the Minister had already refused to carry out his promise to apply the Spens Report to the current capitation fee and that the unity of insurance practitioners had eventually compelled him to do so. The press notices, he said, were meagre and misleading. It ought to have been made clear to the public that what practitioners had asked for was not a given capitation fee but the implementation of the Spens Report. Dr. DAIN said that the Public Relations Committee had been steadily at work for two or three years. Its members were beginners at this job, but they had now learned a good deal about it, and their relations with the Press had greatly improved and were in the main excellent. It was relatively easy to get their case stated in the national newspapers, but less easy in the local ones, and it was here that Panel Committee secretaries in their own districts could help. The Berkshire motion was withdrawn.

If Resignation becomes Effective

A motion by Lancashire asking the committee to circularize individual doctors with a guide as to the conduct of their practices in the event of their resignations becoming effective was accepted by Dr. Gregg for appropriate action.

Among other motions referred to the I.A.C. was one from Birmingham, suggesting that if resignations became operative, practitioners should treat former insurance patients as private patients, charging them the fee adopted for the district and giving them a receipt on a form centrally supplied, analogous to the present G.P.4, enabling the patient to claim reimbursement to the individual doctor's debit and to be placed on the doctor's list as from the date of his resignation or of the issue of the form consequent upon a national settlement.

Congratulations for the Committee

Dr. WOOLLEY moved a resolution of congratulation to the Insurance Acts Committee on its success so far on the question of the capitation fee. This was no formal proposal but a real "Thank you" to the committee, in which he included Dr. Hill. Dr. F. E. GOULD seconded, and the motion was carried by acclamation.

Dr. GREGG said that he had been on the I.A.C. for 25 years, and this was the first occasion on which he could recall a resolution passed in exactly these terms. His committee was a good one, which knew its job thoroughly. He went on to make an appeal for maintained unity. While he always respected those who put forward a minority view, he begged them, once a majority decision had been taken, to sink their own views and pull with the rest.

The Mileage Grant

Dr. R. W. RAE (Staffordshire) moved that immediate steps be taken to secure the heavier weighting of mileage, as suggested in para. 16 of the Spens Report. Country practitioners felt that if the capitation fee was inadequate, mileage was doubly inadequate. Dr. A. SIMPSON (Roxburghshire) urged a substantial increase in mileage remuneration. The motion was carried.

Dr. J. MCCREA (Berkshire) moved that any consideration of the capitation fee should include a proportionate increase of the mileage grant. The grant was not merely a contribution to car expenses: it was quite impossible for the rural practitioner to have as many patients on his list as his colleagues in the town. Dr. GREGG thought it would be better to leave mileage to be dealt with on its merits rather than to claim that the increase

should be proportionate to an increase granted on something else. The Berkshire motion was withdrawn.

Dr. T. O. JONES (Denbighshire) moved that in addition to the heavier weighting of the mileage grant, the payment for distances over four miles should be steeply increased. A doctor in a rural area with a list of 600 had to work much harder than an urban practitioner with a list of 2,000. The urban practitioner had the further advantage that more of his patients attended at the surgery, and when he visited patients he could cover more in a given time. He had also to attend an unusual number of acute cases which in an urban area would be sent to hospital immediately. This motion was referred to the committee.

NATIONAL INSURANCE DEFENCE TRUST

Dr. J. W. BONE (Treasurer of the Trust) said that the amount now held by the Trust was £315,000, entirely in gilt-edged securities. The Trustees had allocated nearly one-third of this to the Emergency Guarantee Fund, and the proposal that a second £100,000 should be so allocated had been noted. In addition the B.M.A. had guaranteed from its own funds another £100,000, so that a total of £300,000 was in waiting should the emergency arise.

Dr. D. L. S. JOHNSTON (Halifax) moved to emphasize the need for vigilance and unity in regard to any new service—irrespective of any inducements which might be made to enter it—and for increased financial support for the Trust by all possible means. Their salvation, he said, lay in themselves, not in the public, in spite of all that had been said about public relations, and the best way to back up the I.A.C. would be to provide an even larger fund. Dr. A. V. RUSSELL (Wolverhampton) supported Halifax, and said that his own constituency was making an immediate and special effort to follow the example of West Bromwich, which had actually paid 101% of its quota of the £1,000,000 objective. The motion was carried.

Dr. W. MACMILLAN (Worcester) moved a resolution drawing attention to the fact that from the extra remuneration recently granted on account by the Minister it was possible immediately for Panel Committees to complete their N.I.D.T. quota without undue hardship, and urging that all committees be recommended to do so without delay. The completion of the quota, he said, was of the highest importance. Worcester, which had contributed 33% of its quota, had agreed to raise its contribution from 4d. *per caput* to 6d. *per caput*, to be deducted from the cheques in January of next year. Dr. W. D. STEEL (Worcester) said that practitioners were receiving an extra payment of 2s. per insured person, and it should be easily possible for committees to raise their quota to 6d., equivalent to one-quarter of the additional sum received. The Worcester motion was carried unanimously.

Dr. OSCAR WILLIAMS (Llanelli) moved that as a token of appreciation of the work of the I.A.C., insurance practitioners be asked to guarantee to the Emergency Guarantee Fund, for one year, whatever additional sum was obtained over and above the present 12s. 6d., as a result of the talks with the Ministry. This would be without prejudice to the increase of the contributions to the Trust Fund as urged by Worcester. Dr. W. JOPE dissented. Why send representatives to the Minister to get as much money as possible and then use the money to fight him? Dr. GREGG said that there was a good deal in Dr. Jope's point. It would be a maladroit move for money to be received exactly in this way, but he saw no reason why practitioners who found themselves in a better financial position than they were before should not search their hearts to determine how far they might increase any guarantee they had already given. It was agreed to pass to the next business.

Dr. J. T. DALY (Worcestershire) moved to request the committee to consider what steps should be taken to aid those practitioners who, having borrowed money to buy their practices, found themselves unable to resign from N.H.I. practice because debarred by their agreements with financial agencies. In one part of Worcestershire the greater number of practitioners were under financial obligations to certain insurance companies, and while wholeheartedly in favour of resigning if the I.A.C. requested them to do so, found it impossible in the absence of some guarantee which would allow them to cut adrift from these obligations. The currency of the loans was dependent on their continuance in medical service under the

Insurance Acts. Dr. GREGG said that there was something here which required to be investigated, but the seriousness of the difficulty for the individual practitioner would be very considerably modified if he was one of a large number all taking the same action. It was inconceivable that reputable doctors which had advanced money, when they learned that the action to be taken was not individual but concerned the whole profession, would fail to assist and co-operate. He was prepared to accept the motion; the circumstances set out, affecting certain practitioners, would have to be faced. The motion was agreed to.

Dr. F. GRAY (London) announced that the London Panel Committee had decided that it would give its full support to the National Insurance Defence Trust, and in future would collect contributions for that fund only.

The report of the Trustees was approved.

NEW ENTRANTS INTO INSURANCE

Dr. W. WOOLLEY (Bristol) moved a resolution suggesting that a new contribution card should be provided with a detachable part containing a space for the employer's signature and details at present given on Form Med. 50 (revised), this part to be presented by the insured person to the doctor of choice and the card to take the place of the medical card which the latter had been received from the Insurance Committee. Dr. P. V. ANDERSON said that it was too much to expect the Minister to do such a thing. Dr. GREGG said that they had been trying for years to find some solution of this new entrant problem, but they were now within measurable distance in probability of the end of this particular service, and the Minister would tell them of the large stocks of existing stationery; the extravagance of undertaking such a departure. Nevertheless, he was prepared to lay the suggestion before the Ministry. The motion was referred to the committee.

On the formal motion of Dr. E. F. BARNARDO (Reading) the recommendation of the Insurance Acts Committee that no pregnant woman should be summoned to a centre for examination by a regional medical officer after the thirty-second week of pregnancy was supported by the Conference.

DISPENSING CAPITATION FEE

Dr. W. N. STEVENS (West Suffolk) asked the Conference to express the opinion that the present dispensing capitation fee was totally inadequate. Dr. PARKER (Swansea) said that in Wales in 1945 the average cost per insured person was 55.12d., an increase of 5d. over 1944, and of no less than 22d. over 1935 and 20d. over 1939 figures. The 55.12d. was the average; the highest figures in 1945 were 69d. per insured person in Brecon and 67d. in Carnarvon. In view of the rising costs they ought to aim at least at a dispensing fee of 5s.

Dr. J. C. PEARCE (Chairman, Rural Practitioners' Subcommittee) said that his subcommittee had done its best to get out the figures supplied by the doctors themselves. His subcommittee was desirous of obtaining figures from practitioners who were careful bookkeepers, and then it would go into the matter again. Dr. STEVENS pointed out that chemists could recover their purchase tax; doctors found it extremely difficult to do so. Dr. GREGG said that the committee was not satisfied that the dispensing fee was adequate, but the difficulty was to obtain the information from practitioners. The West Suffolk motion was carried with one dissenter.

Dr. H. W. POOLER (Derbyshire) moved to request the I.A.C. to consider means whereby the dispensing lists of rural practitioners could be very drastically curtailed. He said that certain rural practitioners in Derbyshire wanted if possible to be relieved of the duty of dispensing, and this for two reasons: (1) those who did not keep a dispenser wanted to be relieved of the additional work, and (2) those who did keep a dispenser wanted to be rid of this additional expense. In certain areas there were chemists from adjoining towns or villages who would be glad to establish a dispensing service at specified times in some of the remoter places if given facilities to do so.

Dr. F. GRAY said that the B.M.A. had a joint committee with the pharmacists, and this question of dispensing in rural areas was one of the matters under discussion. No final conclusions had been reached as yet, though he might say that the pharmacists showed a willingness to do more dispensing than at present.

it he did not think he could hold out any hope for any new arrangements coming into force before April 1, 1948.

Dr. J. A. FRIDHAM said that the Dorset Panel Committee was against such a suggestion as Derbyshire had brought forward. The patient should be considered, and no proper service as available for the patient by means of dispensing arrangements for an hour or two in a village. Even in urban areas a good deal of dissatisfaction with chemists' facilities was expressed, the shops closing a considerable time before the average doctor's surgery was finished. Dr. W. N. STEVENS said that many of his patients had to come five miles to see him, and if they had then to wait three hours to get their medicines would be intolerable.

Dr. GREGG, in accepting the Derbyshire motion for consideration by the Committee, said that there was no reason why a panel Committee in any area should not make special arrangements with local pharmacists.

General Motions

The Conference negatived a motion by Ayrshire concerning the Emergency Guarantee Fund. The decision of the B.M.A. Council was that the unexpended portion of the total fund be returned to the B.M.A., the N.I.D.T., and the individual guarantors in proportion to the amount contributed. Ayrshire wanted a refund to be in the first place in full to individual guarantors in proportion to the amounts they had contributed, and then, should there be any residue, repayment should be made to the B.M.A. and the N.I.D.T.

Dr. N. E. WATERFIELD (Surrey) moved to request the committee to consider whether any hardship was inflicted on any doctors being called up for recruitment, either as specialists or as general duty officers, in the Forces, and, if so, whether his hardship was such that steps should be taken to mitigate it, possibly on lines similar to those taken under somewhat similar circumstances during the war. Dr. GREGG said that the number of doctors engaged in general practice who were called up for general service duty was extremely small and was getting less. General service duty officers were being recruited almost entirely from young doctors who had not yet gone into practice. The motion was agreed to.

A motion by Burton-on-Trent that as long as established general practitioners were being called up for service a protection of practices scheme should be continued was referred to the Committee.

The Conference agreed, on a motion by Swansea, to make strong representations to the Minister to secure adequate supplies of liquid paraffin, olive oil, glucose, and Optrex, for the treatment of insurance and other patients.

THE NATIONAL HEALTH SERVICE PROPOSALS

Goodwill in Practices

Dr. A. BEAUCHAMP (Birmingham) moved:

That this Conference reaffirms the decision of the Special Conference of April, 1946, that there must be no interference with the present custom of buying and selling practices.

Dr. H. W. DONOVAN (Birmingham) seconded.

Statement by Dr. Dain

Dr. GUY DAIN, Chairman of Council, said that this proposal rather led them from National Health Insurance into the realm of the new National Health Service, and possibly as Chairman of Council and of the Negotiating Committee he might say something on this subject. The Minister had made no attempt to meet the situation which the profession had placed before him. He had not retreated from his position with regard to the purchase and sale of practices. He had taken the illogical standpoint that the sale of practices was immoral and was tantamount to the selling of blocks of patients, but apparently he was not prepared to stop the sale and purchase of dentists' practices or of the practices of consultants and specialists who, in certain instances, had bought their practices.

It was to be hoped that in the coming weeks the profession would show by its votes in the plebiscite that it was determined to stand by its principles, one of which was the retention of goodwill in practices. He thought they were in a very strong

position at the moment. They had succeeded in winning the first round or, at any rate, on a show of strength had caused the Minister to alter his mind. It was possible, he hoped, on a further show of strength to persuade him to alter his mind again.

In a few weeks the members of the profession would be asked to answer a question, and it was important that the implications of the question should be understood. If they were in favour of retaining their principles and wished to see them established before any new service was agreed they would vote against the carrying on of any negotiations for the building up of regulations. He was satisfied that any agreement on their part to enter into negotiations on detail while their principles were not accepted would be fatal to any prospect of establishing their principles later on. If they were prepared to act together in the way in which it had been shown that insurance practitioners could act together they would not only establish their principles but obtain a proper remuneration for their services as well.

He instanced two or three important principles which the Act failed to include. One of them was that any practitioner who wished to do so might come into the Service. The Minister had not conceded that, although it was in the National Health Insurance Service. The profession also desired to have the right of appeal to the courts before erasure of a name from the list. If the members of the profession thought that these things were of importance they would vote against their representatives' entering into discussion on the regulations for carrying on the service. They had before them the encouraging example of the profession in Australia where a Government had set up a service which, because it failed to satisfy medical opinion, remained a dead letter. In this country they did not want to see any medical service a dead letter, but they wanted to see one in which they could work with satisfaction to the community and to themselves.

The Council had met on the previous day to consider the question of the plebiscite. The question was a simple one: "Do you wish the Negotiating Committee to institute discussions with the Minister on the subject of the regulations?"

The present position of the Bill was that it was almost through the House of Lords, which had made a number of amendments. These would go back to the House of Commons, and if not accepted would come to the Lords again. The session ended on Nov. 6 or 7, and if the Bill had not received Royal Assent by then it would be a dead letter, and the Government would have to introduce it again and carry it through all its stages next session. It was not expected that any support of their case in the House of Lords would be sufficiently vigorous to stop the passage of the Act this session, though the time was short. Their future depended on their own exertions. It was most important that every doctor should understand the position before he voted in the plebiscite, and it was necessary to get the fullest representation of medical opinion.

Asked what was the position if they did not negotiate and the Minister framed his own regulations, Dr. Dain said that if the profession decided by a sufficient majority to take no part in negotiations the Minister's regulations would be useless, because the Act would have no doctors to work it. The profession could perfectly well stand together. Patients would be treated. From the economic point of view the average doctor's income in this country was derived at least to the extent of two-thirds from private practice. They would not be faced with an enormous economic disaster. They would continue to treat the members of the public as private patients, as the majority were treated to-day. He did not think they should enter upon this with trepidation. If they stood firmly together no real harm could come. The Government was by its programme compelled to produce a service, and it was agreed that such a service to be workable must command the willing acceptance of the medical profession. The conditions on which their willing acceptance depended could be readily stated, and by their own solidity he believed they could get them established. It was for them to see that the medical service was satisfactory. They should not have any difficulty in maintaining a reasonable standard of livelihood in the absence of a public service, and he hoped that they would not be terrified for fear of economic consequences into the acceptance of something of which they disapproved. (Loud applause.)

In reply to a further question he pointed out that there was no real parallel between the Minister's refusal to discuss principles and their own refusal to discuss regulations. The two things were not on the same footing.

Dr. GREGG reminded the Conference that the negotiations now referred to concerned the regulations necessary to bring the scheme into operation. The Minister still refused to negotiate in any way concerning what he called the fundamental principles of the Bill.

The motion reaffirming the decision that there must be no interference with the present custom of buying and selling practices was carried without dissent.

It was announced that the following were the six members of the Insurance Acts Committee who had been elected by the Conference (out of 16 candidates): Drs. A. Beauchamp (Birmingham), I. G. Innes (Hull), J. A. Ireland (Shrewsbury), J. A. Pridham (Dorset), F. M. Rose (Preston), W. Woolley (Bristol).

The Conference closed after according a hearty vote of thanks to its Chairman, Dr. J. A. Brown.

HEARD AT HEADQUARTERS

Mr. Bevan with the Students

The Minister of Health spent two hours with the students the other day, talking about the National Health Service Bill. He began with the affable remark that the British Medical Students' Association was a more important body than the B.M.A., "because you and I will have to live together when some of those presiding over the B.M.A. will only be in a position to require your services." He noticed that the students in a questionnaire had approved a comprehensive health service, but some of their other replies were a little contradictory. The majority desired the ownership and administration of voluntary hospitals to remain unchanged. But, said Mr. Bevan, he or his successor in the House of Commons would have to answer for a service which covered everybody in the country, and he could not do that if he had to work through institutions which denied his authority—"a very obvious thing, but a good many do not seem to have grasped it." "A National Health Service cannot be articulated to self-motivated voluntary hospitals." To have things remain as they were was surely hardly worthy of young and adventurous opinion.

On the other hand he noted that the majority of the students were in favour of general practitioners being remunerated partly by salary. There they did not march with some other medical views. Around this question of salary arose all the charges about "State Slaves," "mere Civil Servants," "regimented doctors," "Bevan's boys." "It is really all nonsense, you know." It had been said that with this scheme in operation all sense of adventure would die out of a man when he qualified. "All poppycock!" Apparently the sense of adventure was sustained if the young practitioner was left to the mercies of the moneylender. His idea in providing a basic salary was to ensure the young doctor his bread-and-butter and leave him the inspiration to get his gammon. Moreover, to a salary could be attached additions for postgraduate attainments, whereas such things could not be appended to a capitation fee.

No Direction

"There is no direction in this Bill," Mr. Bevan told the students. The only direction was that if a young doctor wanted to enter the public service he must, like anyone else, enter the public service where the public service needed him to enter it. He read out the usual figures showing inequality of doctor distribution—one doctor to 1,180 people in Hastings, one to 4,105 in South Shields, and so on. It was said that a doctor should be allowed to settle where he liked. Well, he had never heard that squatters were popular in the medical profession; in fact many young doctors came to him complaining bitterly of restrictive clauses in their agreements as assistants. That was what the profession was doing now; all he was doing was to bring about a negative control by a positive distribution of doctors over the country. He added that it was impossible to introduce a scheme of this kind without treading on corns, and medicine was "a very corny profession." One had only to go back to the conflicts of 1911-12, when the principles now being

advocated so warmly by the medical profession were denounced by the very same people, or their predecessors, as outrageous invasions of liberty. Mr. Bevan was boisterously confident about the success of his scheme. It was far less controversial than it seemed. Many of those who opposed it in public thought better of it in private. It was accepted by the great municipal authorities and, on the whole, by those responsible for the best features in the voluntary hospitals, and the best elements in the profession on the specialist side. "We have still to win the British Medical Association." He gave a side glance at his recent concession over the capitation fee—very pleased it had contented them, and, unlike more famous or more notorious men, he did not care an ounce about prestige—only about getting the best atmosphere in the profession.

The Right of Appeal

On one point Mr. Bevan was less happy. It concerned the question of appeal to the courts. He claimed that what he had done in this Bill was to give an additional safeguard to what existed already in national health insurance; in other words, he was putting in a tribunal between the local executive (equivalent to the insurance committee) and the Minister. What would happen if there was an appeal to the courts and a judge reversed the decision which was the result of all this apparatus? It would mean that the doctor concerned would go back into the Service. Thus the judge, in effect, would be the person who selected those who were under contract with the State. That would be, in Mr. Bevan's view, an intolerable position. Nevertheless, surely the same position arises in any successful action over wrongful dismissal or breach of contract.

The students, who bombarded him with questions for an hour and a quarter, seemed to be very anxious about unorthodox practice. Mr. Bevan's answer was that if anyone wanted to practise an unorthodox form of treatment the best way for him to do it was to get himself entitled to practise in the orthodox manner. He was not against heterodoxy, being a little bit that way himself, but in this legislation he had to keep within the "church," and practitioners must keep within the "church," too, if they wanted to be unorthodox. Many questions were fired at him about the right of private practice. He said that he would regard it as a major defect in the whole scheme if fee-paying continued on any large scale. Indeed, salary and capitation payment would be based on the assumption that very few people would pay fees.

Open Diplomacy

Sir William Douglas, Permanent Secretary of the Ministry of Health, created a very pleasant impression when he met the Insurance Acts Committee the other day. His frank, disarming manner helped to resolve a difficult situation. He had been asked to attend the committee at a moment's notice, and he came from Whitehall forthwith, making a jocular protest against this interference with the traditional Civil Service siesta. He showed a complete understanding of the committee's difficulty. Within half an hour or so, thanks to his co-operation, the committee reached agreement on a recommendation to the Panel Conference, although agreement had seemed impossible after two hours' previous debate.

Restrictive Covenants Discountenanced

The Hospitals Committee at its last meeting decided to reverse a previous decision concerning restrictions on future practice to be imposed on hospital house officers on appointment. Earlier this year the committee considered a letter from a district hospital which stated that the medical staff had requested that a condition should be imposed on a resident house-surgeon who was to be appointed that he should not practise within a radius of ten miles of the hospital during the ten years following the end of his appointment. The Committee was asked whether this was a reasonable procedure, and replied that some restriction was not unreasonable, but that a period of ten years and a radius of ten miles were excessive, and that three years and five miles would meet the case. In some quarters, however, any restriction of this kind was objected to, and was taken to be equivalent to the "negative direction" proposed by Mr. Bevan—indeed, worse than his, because the Minister would apply his direction only when he considered that no vacancy existed, whereas such restrictive covenants would apply irrespective of the needs of the area.

The matter has since been before the Central Ethical Committee, and it believes that there is no ethical justification for imposing such a condition. The view given some years ago by the solicitor, when the question arose in connexion with another hospital, was that while it was difficult to see why the hospital should require such a covenant, it would probably be held to be enforceable in law, and that the radius in this case, five miles, was not so wide as to be likely to lead the court to upset the covenant. In 1928 the Association conducted an inquiry into the subject. Out of 52 hospitals circularized, 44 had no restrictive clause in the agreement. The others had clauses in which the radius ranged from two to ten miles and the period from six months to five years. The Hospitals Committee, after considering the matter afresh, decided after a short debate that any such restriction ought to be dropped.

Correspondence

The Capitation Rate

SIR,—Early reports indicate that the profession is resolved to resign from National Health Insurance work unless it is remunerated at a level consistent with the findings of the Spens Committee. Indeed it would be impossible to find any good reason why we should continue to offer our services at a price that has long been, and is now publicly, recognized to be inadequate. The Spens Report has established our contention that for years the Ministry of Health has obtained our services at a grossly unfair rate. Mr. Bevan might well have disclaimed all responsibility for this and hastened to show that it ranked as one of the social injustices his party were determined to abolish. Instead he had the sheer effrontery to offer us a paltry sum more consistent with the attitude of his predecessors than the spirit of the Spens Report.

Possibly in more ways than one this is a foretaste of the shape of things to come; but we must be most careful not to permit Mr. Bevan, the public, or ourselves to confuse this very clear issue with any negotiations over the new National Health Service. There are some who appear to be anxious to divert this culmination of our old unanimity over the capitation rate to the purpose of an eleventh-hour display of unity in the much more controversial matter of the future Health Service. Just as Mr. Bevan hoped to garnish his Bill with our long overdue deserts, these medical opportunists hope to induce us to spew it out with our universal distaste for his failure to redress standing injustice. Probably neither party will succeed in influencing our attitude by such methods, but confusion of the two issues might easily forfeit public sympathy with us in any action necessary to secure just remuneration under the present system. Probably a majority of our panel patients have no particular reason to dislike the new health legislation and would not be sympathetic with any movement which became identified with opposition to the Government's Bill. On the other hand it may be anticipated that panel patients will be prepared to suffer some inconvenience to support our just claim for adequate pay. That is not a new conception to most wage earners. From a publicity point of view it would be a pity to complicate the sordid but simple little story of Mr. Bevan's bad faith with the enormous diversity of facts and prejudices relating to the National Health Bill.

There is another good reason for refusing to allow either Mr. Bevan or anyone else to confuse the issues: it is important that whatever we may claim or receive under the present system, it should not necessarily be considered adequate to meet the requirements of any system that might take its place. Obviously payment must be related to terms of service in each case, but the Spens Report quite rightly does not prescribe for any particular case; and we should be unwise to permit its application to one situation to modify its bearing on another. In fact whatever service we have in future we must insist on the constant application of the findings of the Spens Committee rather than accept it as a basis simply for adjustment of present capitation fees or initial remuneration in a new service. Any system of payment must in future be related by formula to the cost of living, and if the capitation method is to persist, the rate will also have to be related directly to the number of doctors

and inversely to the total population. We must insist on the sanctity of the Spens Report as the financial standard to be preserved for periodic checking of our position. Let us see to it that on this occasion and every future one it is handled with respect and applied simply and directly to the case in point.—I am, etc.,

Etc.

J. SHACKLETON BAILEY.

The Day's Work

SIR,—At the last meeting of the East Riding Panel Committee the Spens Report came up for consideration. It was then pointed out that although there was a figure of how much a general practitioner ought to earn, no one had ever decided how much work a doctor could be expected to do with reasonable efficiency—i.e., how many of the population one doctor could look after.

Taking the Spens Committee figure of £1,300 as a basis, we find that the average expenses of the practitioner are 40% of his gross earnings, and therefore a net income of £1,300 means a gross income of £2,166. With a capitation fee of 15s. this means a list of 2,888 patients. How much work does this entail? Statistics kept in this area in 1938 show that the average attendance on insured persons was 5.5 per annum; therefore 2,888 patients means 15,884 attendances (visits and surgery) per year. Taking 307 working days (i.e., omitting Sundays and the six public holidays) this gives an average of 51 attendances per day. But it is agreed by all practitioners that the amount of attendance on insured persons has increased during the last eight years, so it is quite fair to take a figure of at least 6, which gives a daily attendance of 56.4. With the capitation fee of 12s. 6d. we get a daily figure of 67.7.

Most of the practitioners in this area find that whereas one-third of their income comes from insured persons, these persons make two-thirds of their work. It is therefore fair to argue that when the whole population can get their medical attention without having to consider doctor's bills, the amount of attendance will be proportionately increased (which may be a good thing for the patient, but not for the doctor). This committee has always held that any National Health Service should be the best, so that no one should think that by going outside the Service he could obtain better treatment, but my colleagues all complain that they cannot do as good work as they would like because to make a reasonable income they have to look after more patients than they can treat efficiently.

The point that our negotiators should consider is, how many patients can a doctor see in a working day of reasonable hours, and give them efficient treatment? Can he see an average of 56.4 patients a day? I doubt it, particularly in a country practice, where many miles have to be covered, and which includes midwifery, accidents, dressings, minor operations, etc., in addition to letter-writing, telephone calls, and if he has no dispenser or secretary, making up medicines and keeping records. I know that there are doctors who say that they have done 70 visits and seen a similar number in their surgery, but this is not doctoring. I might mention here that during the war the Central Medical War Committee decided on a figure of 3,000 to one doctor in an urban district, 2,700 in a semi-urban district, and 2,400 in a rural district; and these were the maximum that a doctor could be expected to attend.

My own opinion is that in peacetime no doctor should be asked to look after more than 2,000 of the population if he is to do his work efficiently and have time to read a medical book occasionally, a little leisure, and see something of his family and friends. If I am correct the Minister of Health will have to alter his ideas of what he should pay the doctors. In conclusion, I note that the Spens Committee stated that its findings were in the 1939 value of money.—I am, etc.,

SIDNEY F. FOURACRE.

Chairman, East Riding Panel and
Local Medical Committee.

Witherssea.

A mass meeting of dentists passed a resolution on Oct. 20 refusing National Health Insurance dental patients at the fees imposed by the Minister of National Insurance. They will be treated as private patients at fees recommended by the Dental Benefit Council. The meeting was the last of a series that has been held throughout England, and it took place in London, at B.M.A. House.

H.M. Forces Appointments

COLONIAL MEDICAL SERVICE

The following appointments have been announced: R. B. Baird, M.B., Ch.B., D. P. Burkitt, M.B., B.Ch., F.R.C.S., A. R. Darlow, M.B., B.S., A. M. Best, M.R.C.S., L.R.C.P., Medical Officers, Uganda; A. M. Barnett, M.R.C.S., L.R.C.P., A. C. Franks, M.R.C.S., L.R.C.P., C. L. Hall, B.M., Ch.B., and W. T. Thom, M.B., Ch.B., Medical Officers, Tanganyika; W. L. Barton, M.B., Ch.B., G. C. Bisley, M.R.C.S., L.R.C.P., P. L. Candler, M.B., B.Ch., W. Waterston, L.R.C.P.&S., and J. R. Connolly, L.R.C.P.&S., Medical Officers, Kenya; P. P. D. Connolly, M.B., B.Ch., and J. H. McDonald, M.B., Ch.B., Senior Medical Officers, Tanganyika; S. C. Buck, M.B., Ch.B., Medical Officer (Pathologist), Northern Rhodesia; M. Calvert, M.B., B.Ch., N. W. J. Hctreed, B.M., B.S., M. C. Keter, M.B., Ch.B., P. R. Cooper, B.M., B.Ch., P. B. Siones, M.B., B.S., and N. Leitch, B.M., B.Ch., Medical Officers, Nigeria; A. H. R. Coombes, M.R.C.S., L.R.C.P., D. W. Goud, M.R.C.S., L.R.C.P., R. W. Holloway, M.D., J. S. Willis, M.D., J. R. Handforth, M.B., B.Ch., Medical Officers, Hong Kong; W. S. Dykes, M.B., Ch.B., and R. J. O'Kane, M.B., Ch.B., Medical Officers, Malaya; M. H. Hughes, B.M., R. F. Antonio, M.B., Ch.B., and G. M. Edington, M.B., Ch.B., Medical Officers, Gold Coast; P. W. J. Searle, M.B., Ch.B., Medical Officer, Grade II, Fiji; W. Sheffield, M.B., Ch.B., and A. J. Evans, Medical Officers, Northern Rhodesia; W. L. Cummings, M.B., Ch.B., District Medical Officer, St. Vincent, Windward Islands; P. G. Griffiths, M.C., M.B., B.Ch., Medical Officer, Fiji; C. H. Gurd, M.B., Ch.B., Medical Officer, St. Helena; A. E. Association Notices

AREAS OF SWINDON AND TROWBRIDGE DIVISIONS

Notice is hereby given by the Council of the British Medical Association to all concerned that the municipal borough of Malmesbury has been transferred from the area of the Swindon Division to that of the Trowbridge Division.

CHARLES HILL,

Secretary.

Oct. 19, 1946.

Diary of Central Meetings

NOVEMBER

- 6. Wed. Ordinary meeting of Council, 10 a.m.
- 8. Fri. G.M.C. Committee, 2 p.m.
- 19. Tues. Undergraduate Subcommittee: (Film Committee), 2 p.m.

Branch and Division Meetings to be Held

NUNEATON AND TAMWORTH DIVISION.—At Red Lion Hotel, Atherstone, Tuesday, Nov. 5, 8.30 p.m. Dr. A. E. Carver: The Importance of a Psychosomatic Approach to the Problems of Everyday Practice.

RICHMOND DIVISION.—At Royal Hospital, Richmond; Friday, Nov. 8, 3 p.m. Clinical meeting.

Meetings of Branches and Divisions

MORPETH DIVISION

A meeting of the Morpeth Division was held on Oct. 11, 1946, with Mr. A. A. Bonar in the chair. A letter was read from Sir Arnold Lawson appealing on behalf of the "Christmas Gifts Fund," and it was agreed to postpone discussion of this matter until next meeting.

The chairman then introduced Mr. J. I. Munro Black, who gave a most interesting address on "Otitis Media," dealing mainly with the great advance in treatment brought about by the introduction of the sulphonamides and penicillin. He subsequently gave a short talk on "Hearing Aids for Deaf Persons." A vote of thanks was proposed by Dr. B. B. Noble and seconded by Dr. T. A. S. Brown.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Fri. (Nov. 1), 5 p.m., Prof. C. A. Pannett: Pancreatic Surgery. Mon., 5 p.m., Mr. Terence Miliin: Surgery of the Prostate. Tues., 5 p.m., Mr. C. Price Thomas: Surgical Treatment of Pulmonary Tuberculosis. Wed., 5 p.m., Prof. R. St. L. Brockman: Intestinal Obstruction.

ROYAL SOCIETY OF MEDICINE

Section of Orthopaedics.—Tues., 8 p.m. Short papers by Mr. R. H. Young: Protrusion of the intervertebral disk. Illustrated by a film. Mr. G. K. McKee: Use of the crossed Trislin nail and tibial graft in fractures of the neck of the femur. Mr. M. C. Wilkinson: Intertrochanteric osteotomy for tuberculosis of the hip. Mr. W. Sayle Creer: Some points about Monteggia fracture.

Section of History of Medicine.—Wed., 2.30 p.m. Paper by Prof. J. J. Izquierdo (Mexico City): The neglect of Harvey's *De Motu Cordis* in Spanish-speaking countries and its recognition after three centuries.

Section of Surgery.—Wed., 8 p.m. Discussion: Treatment of acute peritonitis. To be opened by Prof. John Morley, and Mr. C. G. Rob.

Section of Neurology.—Thurs., 8 p.m. Clinical meeting at Maida Vale Hospital for Nervous Diseases, W.

Clinical Section.—Fri., 5 p.m. (Cases at 4 p.m.)

THE LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—Tues., 5 p.m. Dr. R. T. Brain: Electrotherapeutics. Thurs., 5 p.m. Dr. G. B. Mitchell-Heggs: Penicillin in Diseases of the Skin.

MEDICAL RESEARCH SOCIETY.—At University College Hospital Medical School, Gower Street, W.C., Thurs., 5 p.m. Lecture by Dr. W. J. Kolff: The Artificial Kidney.

POSTGRADUATE NEWS

The 20th Annual Lloyd Roberts Lecture will be delivered in the Physiology Theatre of Manchester University by Prof. Michael Poianyi, F.R.S., on Tuesday, Nov. 19, at 4.15 p.m. Subject: "The Foundations of Academic Freedom."

The Fellowship of Medicine announces: (1) Course of six lectures on Clinical Aspects of Psychiatry, on Tuesdays and Wednesdays (afternoons) at West End Hospital for Nervous Diseases, from Nov. 5 to 20. (2) Course in obstetrics and gynaecology for general practitioners, daily, at Queen Charlotte's Maternity Hospital and Chelsea Hospital for Women, from Nov. 25 to 30.

WEEKLY POSTGRADUATE DIARY

BLACKPOOL: VICTORIA HOSPITAL.—Thurs., 8 p.m. Mr. Thorburn: The Early Diagnosis of Malignant Disease of the Ear, Nose, and Throat.

APPOINTMENTS

LONDON COUNTY COUNCIL.—The following appointments have been made in the mental health services of the Council at the Maudsley Hospital: Assistant Clinical Director; Eric Guttmann, M.D.; Physician, Andrew Paterson, M.D.; Senior Registrars, Marjorie Roth, M.D., and D. N. White, M.B., B.Ch.

ROYAL SUSSEX COUNTY HOSPITAL, Brighton.—Honorary appointments: Consulting Physician, Gladys M. Wauchope, M.D., F.R.C.P., Physician, & Kemball Price, M.D., M.R.C.P., W. A. Bourne, M.D., M.R.C.P., H. O. McOregor, M.D., M.R.C.P., Surgeons, H. J. McCurich, M.S., F.R.C.S., W. R. Forrester Wood, F.R.C.S., Assistant Surgeon, J. C. F. Lloyd Williamson, M.D., F.R.C.S., Ear, Nose, and Throat Surgeons, H. G. Downer, M.B., Ch.B., T. S. Allen, F.R.C.S.Ed., Assistant Ear, Nose, and Throat Surgeon, G. A. Fraser, M.B., Ch.B., Radiotherapist, E. Millington, M.R.C.S., L.R.C.P., Assistant Dermatologist, E. Colin Jones, M.B., B.S., Psychiatrist, A. W. Watt, M.B., Ch.B., D.P.M., Anaesthetist, J. H. Crawford, M.R.C.S., L.R.C.P., R. Binning, M.R.C.S., L.R.C.P.

WILLES, W.H., M.R.C.S., L.R.C.P., D.P.M., Psychiatrist to Nottingham County Borough and Nottinghamshire County Council Child Guidance Centres

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

HEMPHILL.—On Oct. 23, 1946, at Queen Charlotte's Hospital, London, 10 Patricia, wife of Dr. Peter Hemphill, a daughter.

MARRIAGE

THOMAS—HEBERT.—On Oct. 26, 1946, at St. Peter's Church, Llanbedr, Denbighshire, H. Arwel Thomas, County Medical Officer of Health, Wrexham, to Blodwen Herbert, widow of Capt. Reginald Herbert, of Bolton and Winchester.

DEATHS

DAVIDSON.—On Oct. 14, 1946, at Eden Mount, Carlisle, Ian Mackenzie Davidson, M.D., F.R.C.S.Ed., beloved husband of Dr. Josephine Davidson and very dearly loved second son of Mr. and Mrs. Norman Davidson 6, Lynedoch Place, Glasgow, C.3.

FRASER.—On Oct. 8, 1946, at Forthill, Aberdeen (following operation) Roderick Martin Fraser, M.B., Ch.B., aged 47 years, of 2, Bayhead Street, Stormoway.

PEACOCK.—On Oct. 22, 1946, at the East Suffolk and Ipswich Hospital, William Henry Peacock, C.B.E., M.B., beloved husband of Mary Hamilton Peacock, Henry Peacock, Church Street, Shropshire, and formerly of the West African Medical Service.

NAYLOR.—On Oct. 19, 1946, at 49, Longhill Road, Caistor, S.E.6, Maurice Craven Naylor, M.R.C.S., L.R.C.P. (late of Rammarsh), aged 80.

TETRA-ETHYL LEAD POISONING

BY

DAVID A. K. CASSELLS, M.D., M.R.C.P.Ed.

AND

E. C. DODDS, M.V.O., M.D., D.Sc., F.R.C.P., F.R.S.

Director of the Courtauld Institute of Biochemistry, Middlesex Hospital, London

Tetra-ethyl lead is the active ingredient of ethyl fluid, an anti-knock compound which for many years past has been widely used by the oil industry for addition to petrol. The toxic properties of tetra-ethyl lead are well known and have been very completely investigated and described—notably by Kehoe—following the occurrence of cases of poisoning when the manufacture of this substance was begun on a commercial scale in the United States in 1924. The absence hitherto of any cases of tetra-ethyl lead poisoning in this country has probably distracted attention from the possibility of its occurrence, and it may be timely to show how it can occur and to recall the symptoms, diagnosis, and treatment of the condition.

Properties of Tetra-ethyl Lead.—Owing to its ready miscibility with fats and oil, tetra-ethyl lead can be absorbed through the intact skin. The vapour given off is readily absorbed through the pulmonary epithelium, and though the substance is of low volatility its vapour pressure is of great significance toxicologically, since it is chiefly from inhalation of the vapour that poisoning is liable to occur. Air saturated with its vapour at ordinary temperatures contains approximately 5 mg. of lead per litre. Its toxicity is a function of the lead content and not of any peculiar qualities characteristic of the compound, but its fat-soluble character allows selective localization in the nervous tissues of the body, and for this reason tetra-ethyl lead poisoning is essentially a central nervous system intoxication (Kehoe, 1925, 1927).

Aetiology

The risks of tetra-ethyl lead poisoning occur, first, in the manufacture of tetra-ethyl lead and of ethyl fluid, the latter containing 60% by weight of tetra-ethyl lead and being the form in which the compound is added to petrol; and, secondly, in the blending of ethyl fluid with petrol. These processes, however, are so well controlled and their hazards so fully understood and so vigilantly guarded against that the occurrence of other than the mildest manifestations of lead absorption is very rare in the manufacture of the product and virtually unknown in lead-blending (Kehoe, 1934; Kehoe and Machle, unpublished data, 1936).

In addition the hazard involved in the cleaning of storage tanks which have contained leaded petrol has long been recognized. A sediment which can be likened to a muddy sludge is deposited on the bottom of every bulk-petrol-storage tank after a period of time. When leaded petrol is stored this sludge contains organic lead compounds and as a result is highly toxic in the same way as is concentrated tetra-ethyl lead, and may, from inhalation of its vapour during cleaning operations, give rise to similar acute and fatal illness. Machle (1935) reports 11 out of 17 cases of lead poisoning as occurring in this way between 1930 and 1935 in the United States.

The possibility of the occurrence of lead poisoning in the distributive and allied trades and among the general public

from the use of leaded petrol, where the concentration of lead has not exceeded approximately 1 in 1,300, has been widely investigated and uniformly discounted (Kehoe, Thamann, and Cholak, 1934, 1936; Final Report of Departmental Committee, 1930; Lind, 1936). Thus in the consideration of tetra-ethyl lead poisoning it is important to distinguish between contact with the concentrated products which are potentially toxic and the diluted leaded petrol which in normal concentrations is relatively innocuous.

In this country up to 1940 the only opportunity of contact with the concentrated product was in the blending of imported ethyl fluid with petrol. Blending was carried out in several refineries and depots throughout the country by a group of some 300 men. The process of blending was a standardized one, and in addition the men were under careful medical supervision. No cases of lead poisoning or any clinical evidence of lead absorption were noted among this group up to 1943. Laboratory workers were similarly controlled, and were equally free from toxic effects (Boldero and Robertson, personal communication).

After the outbreak of war the opportunities of contact with tetra-ethyl lead in this country increased. The manufacture of tetra-ethyl lead and of ethyl fluid was begun in 1940, and has been carried on ever since; but, under the most carefully controlled plant conditions and with very complete medical supervision, including regular laboratory investigations, no cases of poisoning have occurred. The workmen, tested before employment, showed a mean urinary lead excretion of 0.0328 mg. per litre. With exposure to lead this had risen a year later to 0.0774 mg. per litre, but with improvement in technique and with experience it had fallen in a further year's time to 0.0562 mg., and has remained in this region for the past four years, the latest figure being 0.0493 mg. per litre. Furthermore, the amount of ethyl fluid blending increased for a time, but laboratory analysis of urine samples from 1943 onwards showed no evidence of lead absorption attributable to this operation, nor did medical examination reveal any clinical evidence of lead intoxication.

Thus experience in this country followed that of the United States in the absence of toxic sequelae from the manufacture and handling of the concentrated products once the dangers were understood and the hazards controlled.

Throughout the war all aviation petrol contained tetra-ethyl lead, and from approximately the beginning of 1942 all petrol used by the Armed Forces, and to a large extent by the civil population also, contained that substance. During the war, however, many operations involving the handling, packing, and distribution of such petrol—much of it in small containers—had to be carried out under conditions which would not have been tolerated during peacetime. Much of the work was done by hand under security conditions of black-out precautions and

blast protection, which seriously interfered with the basic safety measures of effective ventilation.

Can-filling; Can-washing

Reports from abroad of certain cases of lead poisoning, characterized by the sudden onset of cerebral symptoms and occasionally ending fatally, drew attention to the possible hazards connected with the filling of very large numbers of petrol cans under conditions of operation described above.

Although it was realized that the absence of tropical conditions and the intermittent nature of the work rendered less likely the occurrence of such cases in this country, an investigation of can-filling was carried out in two localities in Britain. No cases showing clinical signs or symptoms attributable to tetra-ethyl lead poisoning were uncovered, but laboratory analysis of urine samples from a random selection of male and female can-fillers and can-washers showed that lead was present in such concentration as to point to a possibly hazardous lead exposure (Table I). Furthermore, estimation of the

amount of lead in the atmosphere showed a higher concentration than was considered desirable for prolonged periods of work in the buildings concerned, being higher than the safe limit of 1.5 mg. of lead per 10 cubic metres of air defined by the American Public Health Association (1943) (Table II).

TABLE II.—Average Concentration of Lead in Atmosphere in Can-filling Buildings in Milligrammes of Lead per 10 Cubic Metres of Air

		Plant X		Plant Y	
		Day	Night	Day	Night
Face level	11.9	4.78	5.21	2.26
Random point in building	4.65	3.37	1.2	1.2

Conditions were much improved by the installation of more efficient ventilation, by the introduction of mechanical filling, and by the enclosure of the filling machine, the average amount of lead in air being reduced to 2 mg. per 10 cubic metres. Gradual diminution in the urinary lead concentrations of the operators then occurred, and this was further hastened in the case of can-washers by the substitution of unleaded fuel in washing out the cans—a step which had the additional effect of reducing the amount of lead in the atmosphere of their building to 1 mg. per 10 cubic metres. Urine analysis, continued for a few months after these operations had ceased, showed a further drop in the mean lead urinary concentration to 0.08 mg. per litre.

Thus although there were no clinical symptoms of lead poisoning the degree of lead absorption was potentially too and could only have derived from exposure to leaded petrol.

Other Refinery Operations

It was thought, too, that the conditions under which petrol had to be handled from time to time gave rise to increased lead absorption by other refinery operators, since some men who were giving urine samples on account of occasional ethanol fluid blending, began to show higher urinary lead concentrations than the operation of blending could explain, especially since the amount of blending had by then greatly diminished.

Such men were engaged in tank-dipping, in the filling of road and rail cars, and more especially in attending to pumps in underground or semi-underground pump-houses. Here some leakage of petrol always occurred and the atmosphere smelt strongly of spirit; nor were the men too careful in running the ventilation system, especially in winter-time. Some of these men showed mild symptoms of intoxication as evidenced by disturbance of sleep and the occurrence of fantastic dreams, while at the same time they had urinary lead concentrations as high as 0.275 mg. per litre. Two of the men for a time compared their dreams each morning; another expressed himself as unable to compose his mind sufficient to go to sleep. No more serious manifestations occurred, however, and with the success of the Normandy campaign in the handling of large quantities of such fuel, and consequently in the amount of exposure, diminished very considerably and all symptoms disappeared.

Lead absorption also seemed to be greater in operators of those depots which, for safety's sake, had been built below the level of the surrounding countryside and in which, as consequence, natural ventilation was poor. Thus while the mean urinary lead concentration of all the lead-blenders in the country was 0.0535 mg. per litre (± 0.0338), that of the operators in two such depots was 0.157 and 0.188 mg. per litre.* On clinical examination these men showed no evidence of lead intoxication, and would have attracted no attention had not their urinary lead figures been so much higher than normal.

Tank-cleaning

After the cessation of hostilities a number of tanks which had been specially constructed for war purposes, and notably those which had contained aviation petrol, were no longer required in service. Accordingly it was decided to close them down after they had been cleaned. It was known that the sludge on the bottom of all these tanks contained organic lead compounds and that the operation of cleaning required strict observance of precautions designed to protect workmen from exposure to these compounds. The sludge was present in a storage tanks which had contained leaded petrol, irrespective of the lead concentration of the fuel; it contained organic lead compounds varying in amount from 0.044 to 0.084%, a series where analysis was carried out. The vast majority of the tanks in question were underground, and for this reason they presented far more serious cleaning problems than the normally associated with the usual type of bulk-petrol-storage tank built above ground.

Briefly, the operation of tank-cleaning consisted in sweeping the floor and scraping the sides and supporting pillars of underground tanks of 500, 2,000, and 4,000 tons capacity after the petrol had been pumped out and the air rendered gas-free by ventilation. Men engaged in the work were required to wear an air-line mask and were supplied with a complete outfit of clothing, including boots, gloves, and headgear. A warm bath was provided at the end of the day before the ordinary clothing was resumed.

The programme of tank-cleaning was begun in different parts of the country in the autumn of 1945, and in some instances the regulations governing the cleaning procedure came to be overlooked or disobeyed, with the result that several cases of poisoning occurred, while elsewhere the operation was carried through for months without even the mildest lead absorption resulting.

In all, there occurred twenty-five cases of tetra-ethyl lead poisoning of varying severity, two of them being fatal. Of four very severe cases, three occurred in foremen or charge-hands.

Case Histories

Case 1.—Aged 42. Started tank-cleaning on Oct. 31. After 3 weeks he was suffering from lack of appetite and broken up, and his mates thought he looked ill. He had a long week-end break and resumed work on Nov. 20 for a further week, during which he slept badly and had troublesome dreams, in one of which he had constantly to be brushing rats off his chest while he lay in bed. He felt sick, but couldn't vomit. On Nov. 28 his behaviour became odd in that he interfered with the apparatus used by the other men and complained of a loss of money which he had not in fact sustained. In the evening he became noisy and violent, and appeared to be having fits. He was admitted to hospital in the early morning of Nov. 28, and was found to be in a convulsion, deeply cyanosed, with an almost imperceptible pulse; he died within minutes of admission. At necropsy a few white patches were seen on the arachnoid which were reported as suggestive of lepto-meningitis or of lead or alcoholic poisoning. Sections of liver, spleen, stomach, and brain showed only the general appearances of degenerative change of varying severity. Analysis of the organs for lead showed the following, in milligrammes of lead per 100 g. wet tissue: brain, 0.74; liver, 2.35; spleen, 0.29; kidneys, 0.79. Normal maximum concentrations of lead in these tissues may be taken as brain, 0.09; liver, 0.28; spleen, 0.07; kidneys, 0.16 (American Public Health Association, 1943). Since tank-cleaners at this time were not under medical supervision, no sample of urine was available for analysis, but the quantity of lead found in the tissues, along with the symptoms described, left no doubt that the cause of death was acute lead poisoning.

Case 2.—Began tank-cleaning on Oct. 31, and first complained of "sleeplessness" on Nov. 16. He had a week-end break, during which he was restless by day, slept badly, and suffered from a mild diarrhoea for two days. He resumed work on Nov. 20 and continued to have insomnia. A few days later his letter home to his wife was confused and queer; he contradicted himself in it several times. He continued at work until Nov. 29, when he came rambling in his talk. He said he felt very weak and that he must go off and rest. He was admitted to hospital later on the same day, restless and violent. He was confused, amnesic, and orientated in time and place. He was suspicious, impulsive, violent, and suicidal, requiring continuous strict nursing supervision. His blood pressure was 108/60 while violent, the lowest reading being 94/60 during a quiet spell. The pulse rate ranged from 72 to 84, and his temperature was subnormal. Superficial reflexes were brisk, deep reflexes diminished, plantar responses flexor; cranial reflexes appeared normal. There was some incontinence of urine, and later a double incontinence. Blood examination showed 4.65 million red cells, 94% haemoglobin, 8,750 white cells, and no punctate basophilia or stippling of the red cells. Urine on Dec. 11 showed 0.440 mg. lead per litre, specific gravity 1014; on Dec. 19 0.98 mg. per litre, specific gravity 1020. Blood urea was 65 mg. per 100 ml. on Dec. 11, and 30 mg. per 100 ml. on Dec. 21. He was given glucose-saline and magnesium sulphate intravenously and received strong sedation: 40 ml. hexobarbitone intravenously between Dec. 4 and 6, 127.5 gr. (8.3 g.) "nembutal" (pentobarbitone sodium) between Dec. 4 and 18, and 14 litres glucose-saline with 1 g. magnesium sulphate intravenously between Dec. 4 and 15. His condition gradually deteriorated. He developed frequent muscular twitches and attacks of spasticity and was restless, talkative, and hallucinated. On other days he was quieter, but gradually he became weaker and lost much weight; he was semiconscious by Dec. 24. Next day there was a marked change in his condition. He became entirely rational; the twitches ceased; bowel and bladder control were regained; at night he slept well, and from that day he steadily improved. His blood pressure was 110/70 at this time, but a week later it was 120/80. His weight was only 7 st. 4.5 kg.). March 26 he weighed 12 st. 4 lb. (78 kg.) and his blood pressure was 140/85, pulse rate 72, temperature 98° F. (36.7° C.). His only recollection of the illness was of his dreams, in which he was usually struggling against terrific odds, but always successfully. His urinary lead was 0.086 mg. per litre, specific gravity 1013; and he complained only of slight stiffness in both knees. His condition otherwise, both physically and mentally, was normal.

Case 3.—Aged 43. Started tank-cleaning on Nov. 13, spending between five and six hours daily in the tanks. On Nov. 21 he suffered from nausea and vomiting in the evening and was off work next day. On Nov. 28 he had diarrhoea and vomiting, and was sweating and tremulous; he had difficulty in falling asleep and spent most of the night talking and smoking. He was irritable and excited. On next day by his doctor, he was thought to be suffering from influenza gastro-enteritis. He spent four or five days in bed but could not sleep, or such sleep as he had was broken by frightening dreams. In one of these he was seized by an octopus and had to fight with a knife in order to escape. He twitched during sleep. He then began to be odd in his behaviour, passing strange remarks and quoting scripture, doing everything in a great hurry and

shouting instead of talking quietly, and he seemed very nervous. On Jan. 2 he was seen by a psychiatrist, who found him confused and depressed and to have delusional ideas, and who recommended his admission to a mental hospital. By Jan. 8 he had lost between one and two stones (6-12 kg.) in weight. He was restless and somewhat inarticulate. His colour was good. His pulse rate was 48, temperature 97.2° F. (36.2° C.), and blood pressure 90/55. His superficial and deep reflexes were exaggerated. His movements were clumsy and spasmodic, but muscle power and tone were good. Mental confusion and delusional ideas were still present. Blood examination showed no punctate basophilia or polychromasia. Urinary lead concentration was 0.215 mg. per litre, specific gravity 1014, six weeks after his last exposure. He became violent a few days later and was admitted to a mental hospital in a state of acute delirious mania. During the first 24 hours he received four injections of 2 ml. of "sominifaine." On Jan. 21 he was still a little confused at times and suspicious, but he had made some progress and his blood pressure had risen to 110/60. He improved steadily and was mentally normal by Feb. 8, when his urinary lead concentration was 0.295 mg. per litre. He was discharged on April 1, mentally well and in a much improved physical condition. His urinary lead concentrations gradually diminished as follows: Feb. 18, 0.210; March 20, 0.135; May 2, 0.091; June 28, 0.063 mg. per litre.

Case 4.—Aged 31. Began tank-cleaning on Oct. 31, and had difficulty in falling asleep as early as the night of Nov. 1. He continued at work till Nov. 7, when he felt light-headed and very tired. He saw a doctor on Nov. 8 and was sent home for a week. He continued to sleep badly in spite of sedation, but his appetite was good. He returned to work on Nov. 20 and after one day felt sick and nervous and could not eat his breakfast. He returned home, where his appetite improved, but his sleep was broken by nightmarish dreams. He remained under his doctor's care till Dec. 3, when he was certified fit to resume work. On that day news of the death of a fellow workman was received, and he was re-certified as unfit for work. On Dec. 7 he looked well and had a good colour, but was a little confused mentally and apt to repeat himself. He had a fine tremor of hands and tongue. All reflexes were exaggerated except the biceps jerk, which was only just elicited. Muscle power and tone were good, pulse rate 48, blood pressure 110/55. Blood examination showed no punctate basophilia or polychromasia. The urinary lead concentration was 0.350 mg. per litre, specific gravity 1025, seven weeks after his last exposure. With ordinary convalescent treatment and mild activity in the open air, he made a good recovery and was fit for work a month later.

Case 5.—Aged 33. Started tank-cleaning on Oct. 31 and worked till Nov. 6, when he felt queer about the stomach and bought some stomach powder, after taking which he ate a good tea. He could not sleep that night and lay awake till morning. He could not eat his breakfast. He saw a local doctor and returned home to bed. He stated that he had no recollection of anything thereafter for a week or two. Seen by his doctor on Nov. 7, his case was diagnosed as "gastritis"—his appetite was poor and he had vomited several times. He slept very little even with the help of sleeping tablets until nearly a week had elapsed. He was sent to see a consultant with regard to his stomach, and was referred to a psychiatrist, who found him in a muddled anxious state just as if he was recovering from a hysterical fugue. He showed no sign of mental confusion or of organic change in the central nervous system. The picture was that of a neurosis. Blood examination on Dec. 6 showed 4.8 million red cells, 98% haemoglobin, 7,600 white cells; a few punctate basophils were seen, but not enough to justify a diagnosis of lead poisoning. A further blood examination on Dec. 7 showed no abnormality of any sort. His pulse rate was 78, blood pressure 120/80. Urinary lead concentration was 0.210 mg. per litre, specific gravity 1019, two months after his last exposure. He steadily improved in health and was fit for work a month later.

Case 6.—Aged 38. Began tank-cleaning on Jan. 2 and continued for one week. On Jan. 9 he felt sick, vomited once, and had severe diarrhoea with no abdominal pain. He had difficulty in falling asleep, and his sleep was fitful and troubled by weird, at times terrifying, dreams in which quaint human beings and animals figured. He was certified by his doctor as suffering from gastro-enteritis and did not return to work. The stomach condition settled down within a day or two, but his appetite remained poor and the sleeplessness persisted. During the day he was restless, irritable, and nervy, and wanted to be on the move all the time. On Jan. 15 his doctor thought him neurasthenic, especially as he had difficulty in passing urine from time to time. On Jan. 19 he looked better, though still anxious and apprehensive. Superficial reflexes were brisk, deep reflexes not exaggerated, muscle power and tone both good. There was some coarse tremor of hands and fingers, with some incoordination of movement. Blood pressure 112/60; pulse rate 64; urinary lead concentration 0.455 mg. per litre, specific gravity 1025. On Jan. 21 he was thought to be progressing satisfactorily since he was sleeping better and his appetite had improved. On the morning of Jan. 23 he suddenly became worse with maniacal

symptoms and delusions, trembling violently, sweating profusely, and talking incoherently. He was given 2 gr. (0.13 g.) of "luminal" (phenobarbitone), repeated in four hours, without effect; by evening he was in a state of acute mania, screaming at the top of his voice, and had to be forcibly restrained in bed. He was quite disorientated in time and place. There were no convulsions, and he died soon afterwards. At necropsy there were no changes except a few subserous petechiae in the heart and pericardium. Analysis of the organs showed the following in milligrammes of lead per 100 g. of wet tissue: brain, 0.6; liver, 2.5; spleen, 0.27; kidneys, 1.2.

Nineteen more men suffered ill effects. Nine of these at one depot had a mean urinary lead excretion of 0.249 mg. per litre, with a range of 0.110 to 0.480 mg. Their symptoms, in order of frequency, were: sleeplessness (including difficulty in falling asleep), broken sleep, and troubled dreams; a nasty sweet taste in the mouth and a bad smell to the breath; lack of appetite; diarrhoea with or without abdominal pain; trembling, shakiness, giddiness; complaint of loss of weight. On examination most of the men displayed increased deep and superficial reflexes, a slow pulse, and lowered blood pressure; some showed a tremor of hands and tongue. None showed mental confusion. There was no basophilic stippling of the red cells.

Six men at another depot, after one or two weeks of tank-cleaning, suffered from sleeplessness shortly followed by lack of appetite and, in some cases, bowel movements which were "watery and slimy—not a real motion." Here it was only after one man had consulted his doctor about insomnia and had been advised to have a change of work that mention of this symptom was made, and all discovered they had been having the same experience. They had been explaining away their sleeplessness to themselves in various ways—e.g., lack of exercise in the winter-time. The supervisor had attributed his insomnia to "worrying needlessly about the job and the men." These men, three months after ceasing this work, had a mean urinary lead concentration of 0.143 mg. per litre, with a range of 0.078 to 0.215 mg. Blood examinations at this time showed no stippling of the red cells or any other abnormality.

Four men at yet another depot showed a mean urinary lead concentration of 0.210 mg. per litre, with a range of 0.175 mg. to 0.240 mg. They had shown similar symptoms—viz., sleeplessness, anorexia, and nausea. Two of them had induced vomiting in an attempt to rid themselves of the feeling of sickness. One man had auditory hallucinations in the form of voices talking to him and people walking behind him, and was considered by his doctor to be suffering from an anxiety state, from which he took about six weeks to recover. None showed any red blood cell changes.

By contrast, 15 men who had done this same work continuously for three months under careful supervision showed a mean urinary lead concentration of 0.048 mg. per litre. The range was from 0.016 to 0.073 mg. except for one case where the figure was 0.135 mg. All these men were symptomless, all had put on weight, and their state of health was the envy of their friends and relatives.

Symptoms

The earliest symptoms in 25 cases of tetra-ethyl lead poisoning were disturbance of sleep and symptoms referable to the alimentary tract. The classical signs and symptoms of lead poisoning—viz., abdominal colic, tremors and fibrillary twitchings, myalgia, neuralgia, constipation, pallor, blue line on the gums, paralyses, stippling of the red blood cells, and punctate basophilia—either did not occur or were a very minor part indeed of the picture.

The earliest indication, often coming on within the first week of exposure, was sleeplessness. A healthy man who regularly went to sleep about 10.30 p.m., "as soon as my head touched the pillow," would lie awake till 2 or 3 a.m., sleep for an hour, often with troubled dreams, wake up with a start, and perhaps snatch another hour of restless slumber before morning, or else find the morning arrive without further sleep. Following shortly upon insomnia, only rarely preceding it, came alimentary tract disturbance—lack of appetite, nausea, vomiting, and diarrhoea of varying severity with no abdominal pain. Subjective nervous symptoms were next in evidence—such as irritability, restlessness, nervousness, and anxiety, possibly tiredness.

The signs at this time were a slow pulse, subnormal temperature, low blood pressure, increased reflexes, and a slight loss of

body weight. With longer or more severe exposure the signs and symptoms progressed to increasing tiredness and loss of body weight, tremor, muscular weakness and twitching, oddities of behaviour, and evidences of mental confusion, and then, quite abruptly, came the onset of acute maniacal symptoms with suicidal tendencies, or the occurrence of a convulsion. Machle (1935) states that in general a given patient will manifest a type of mental response characteristic for him, and not related to the severity of his illness or its stage, but apparently dependent on his mental background. We agree that this was so in this series of cases.

Pallor was not a feature of any of the cases, nor did punctate basophilia occur. Some cases had been referred to a pathologist for blood examination, on account of a suspicion that it might be the cause of the illness, and had been reported "not suffering from lead poisoning" because of the absence of punctate basophilia.

Diagnosis

The diagnosis depends upon the occurrence of such symptoms as have been described, along with the history of exposure to a severe lead hazard. Recognition of what constitutes a severe lead hazard is all-important.

Urinary lead concentration will give some idea of the degree of exposure. If this is less than 0.1 mg. per litre at a time when symptoms of the above nature are displayed, tetra-ethyl lead is unlikely to be the cause. Mild symptoms may occur with a figure of 0.15 mg., but generally it is above this level and in severe cases it is more likely to be in the region of 0.3 mg. or more. Kehoe (1942) states that the upper limit of safe lead exposure as defined on the basis of urinary lead excretion of exposed workmen is represented by a mean value of approximately 0.10 mg. lead per litre for samples that exceed 0.15 mg. only infrequently and 0.20 mg. per litre rarely.

If a 24-hour sample of urine is obtained without unduly large quantities of fluids having been consumed previously, the urinary lead concentration figure may be accepted as it stands. If a single sample is analysed, varying in quantity from approximately 75 to 350 ml., its specific gravity should be taken into account in assessing the significance of the lead concentration. A procedure which has some value in this respect is to multiply the "mg. per litre" figure by 24/G, where G=1,000 (S.G. of sample, 1) (Levi and Fahy, 1945). A high lead concentration in a sample of low specific gravity obviously carries more significance than the same concentration in a sample of high specific gravity.

It is essential in collecting a sample to use a chemically clean container—not necessarily sterile—one which has been washed out with concentrated redistilled nitric acid and with doubly distilled water. One is dealing with microgrammes of lead, and unless a properly prepared container is used the figure obtained will be unduly high. In collection, the sample is passed directly into the container without using any intermediate vessel.

Among the lesions which may simulate this condition are encephalitis due to infection, neurosyphilis, unlocalized brain tumour, cerebral arteriosclerosis, uraemia, and cerebral manifestations of pellagra. Other types of cerebral intoxication caused by alcohol, mercury, carbon monoxide, and overdoses with drugs such as bromides and barbiturates must also be considered. It should be remembered that unquestionably severe lead exposure is required to cause lead encephalopathy in the adult (American Public Health Association, 1943).

The absence of stippling does not rule out tetra-ethyl lead poisoning; basophilic stippling of the red cells is common, absent, and was absent in all the cases described in this series.

Prognosis.—Death may occur rapidly within a few hours of the acute onset or may be delayed for some weeks. If death does not occur within this time, recovery is usually complete. There have been no permanent cerebral sequelae in this series.

Prevention

The careful observance of regulations in carrying out operations connected with tetra-ethyl lead will prevent the occurrence of poisoning, since the hazards are well understood and guarded against. Intelligent and unremitting supervision of the men is called for, and should be the responsibility of someone of higher status than foreman or charge-hand. A foreman, who died, neglected to take precautions and

ported to have said that he had worked with petrol all his life and it had never hurt him. One charge-hand, another case, thought that fifteen years of work with petrol solved him from the necessity for taking precautions.

Treatment

All that is necessary in the milder cases is removal from exposure, light exercise in the open air, a normal diet with plenty of fluids, and the relief of sleeplessness by adequate doses of a suitable sedative, preferably one of the barbiturates. The treatment of the severe case calls for strict nursing supervision in view of the impulsive suicidal tendencies sometimes displayed, and for adequate fluid intake and sedation.

Glucose, 5% in saline, may be given intravenously up to litres per day. If given as a drip, hexobarbitone may be added. "Somnifaine" and pentobarbitone sodium are other suitable sedatives, and may be given in repeated full doses to obtain rest. A retention enema of 4 to 6 oz. (110-170 g.) of saturated solution of magnesium sulphate often has a quieting effect when it can be retained. Morphine is contraindicated. Lachle (1935) recommends the intravenous administration of from 2 to 4 g. of magnesium sulphate in 2% solution accompanied by doses of pentobarbitone sodium up to 15 gr. (1 g.) orally by mouth. Reference to Case 2 of this series will give some idea of the amount of sedation which may be required in a severe case.

Ample fluids should be given throughout subsequent convalescence to aid the elimination of lead. After a severe exposure many months may elapse before the urinary lead concentration reaches a normal figure.

Summary

The properties of tetra-ethyl lead are briefly recalled.

The opportunities to develop tetra-ethyl lead poisoning in this country are described.

Twenty-five cases of tetra-ethyl lead poisoning of varying degrees of severity occurred during tank-cleaning operations, and six of the cases are described in detail.

The symptoms, diagnosis, and treatment of tetra-ethyl lead poisoning are discussed briefly.

We are indebted to Dr. R. W. Zeitlin for his help in two of these cases, and especially for his care of one of them throughout its course to a happy conclusion; also to Dr. Stanley H. Coleman, Dr. R. E. Hemphill, and Dr. G. Schwizer for their assistance in the other cases. The chemical analytical work upon which these observations are based was carried out in the Courtauld Institute by Mr. E. R. Smith. The blood examinations were performed by Dr. R. L. Harding, and to both of these gentlemen we wish to express our thanks.

The first number of *Anaesthesia*, the journal of the Association of Anaesthetists of Great Britain and Ireland, has now been published. It opens with a foreword by Sir Alfred Webb-Johnson, M.R.C.S., wishing the journal every success, and noting that the year of celebration of the centenary of the first operation under general anaesthesia in this country is a most opportune time for founding a journal which will make British teaching and records of discovery and achievement available for the medical profession throughout the world. The editor, Dr. C. Langton Hewer, contributes a note giving the reasons for launching *Anaesthesia*, and this is followed by an article on the inception and purpose of the Association of Anaesthetists written by Dr. H. W. Featherstone, its first president, and another, on the centenary of anaesthesia in Great Britain, by Dr. A. D. Marston, who now holds that office. The rest of the issue is taken up with short practical articles, a review, and some abstracts and items of news. *Anaesthesia* is published quarterly from 24, Thayer Street, W.1.

POST-PENICILLIN JAUNDICE

BY

ROBERT R. HUGHES, M.D., M.R.C.P.

Assistant Physician, Royal Southern Hospital, Liverpool;
Late Medical Specialist, R.A.M.C.

During recent years increasing numbers of cases have been reported in which infective hepatitis has been conveyed to patients by means of an infected injection. The cases fall naturally into two groups, the first of these being cases in which infected serum has been injected either intravenously or intramuscularly. Beeson (1943), Morgan and Williamson (1943), Steiner (1944), and other authors have reported the occurrence of jaundice after transfusion with whole blood or blood plasma. Similarly, hepatitis has followed administration of convalescent serum in the treatment of mumps and measles; jaundice has also occurred after yellow fever immunization where the vaccine contained human blood serum. Experimentally the disease has been transmitted to human volunteers by injection of blood or serum from patients in the pre-icteric or early icteric stages; this experimental work was summarized by McCallum (1944).

Into the second group fall those cases in which the disease may be conveyed by an infected needle or syringe. Salaman *et al.* (1944) reported a high incidence of jaundice in patients receiving intravenous injections of arsenic for syphilis at the Royal Victoria Hospital, Netley, and showed that the incidence of this condition could be much reduced by careful sterilization of needles and syringes. Sheehan (1944) reported further such cases, and considered that hepatitis following the administration of neoarsphenamine was due to the transmission of a blood-borne virus from one patient to another by unsterile syringes. Droller (1945) described an outbreak of jaundice at a diabetic clinic due to the collection of blood for blood-sugar estimation, and Sheehan (1944) reported cases following the withdrawal of blood for estimation of the erythrocyte sedimentation rate. It is here of interest to recall that Murray (1930) reported a high incidence of jaundice in patients treated with intravenous acriflavine for gonorrhoea; there can be little doubt from his description that the cases were identical with those at present under discussion.

Case Histories (Military General Hospitals)

During the past few months, while working in military general hospitals in India, it was noted with interest that a large number of cases of infective hepatitis admitted to medical wards gave a history of having received a course of penicillin injections within the previous seven months. A total of 124 cases of hepatitis were seen, and 36 of these were found to have had penicillin treatment. Clinically these cases were indistinguishable from those of infective hepatitis, post-arsphenamine jaundice, and homologous-serum jaundice admitted during the same period; hence it is unnecessary to describe the history of each case separately and in detail.

The initial symptoms were loss of appetite, abdominal discomfort, flatulence, nausea, and occasional vomiting, followed four or five days later by the onset of jaundice. On admission to hospital there were generally a slight fever for a few days, a moderate degree of icterus, and a palpable tender liver; the urine contained bile salts and bile pigments, and there was a moderate degree of granulopenia and also a raised icteric index or bilirubinaemia. One or two of these patients were seriously ill for a few days, but the majority of cases were quite mild; with strict bed rest the fever and other symptoms rapidly subsided, the jaundice cleared, and the patient was fit for discharge from hospital at the end of three or four weeks. There were no fatal cases. Table I gives a more detailed analysis of the cases seen.

TABLE I.—Analysis of Cases of Infective Hepatitis

Total number of cases of infective hepatitis	124
Number of these cases with a history of penicillin injections	
within the previous 7 months	36
Cases of gonorrhoea treated with penicillin*	9
Cases of syphilis treated with penicillin*	15
Cases of gunshot wounds treated with penicillin	2
Dermatological cases treated with penicillin	1
Cases of syphilis treated with penicillin but had had injections of arsenic and bismuth	5
Cases of gunshot wounds treated with penicillin but had received blood or plasma transfusions	5

* One case is included in both these groups, as the patient had gonorrhoea and later syphilis within the relevant period; both these diseases were treated with penicillin.

If the last two groups in Table I are excluded as possible cases of post-arsphenamine and homologous-serum jaundice there are left 26 cases (or 21% of the total number seen) in which the jaundice might be ascribed to penicillin treatment. Further details of these 26 cases are given in Table II.

TABLE II.—Clinical Details of Cases of Post-penicillin Jaundice

Case No.	Age	Disease	Dose of Penicillin (units)	Date Drug was Started	Date Drug was Stopped	Date of Onset of Hepatitis	Interval in Days	
							Min.	Max.
1	23	Syphilis	2,000,000	16/2/45	28/2/45	22/4/45	53	65
2	22	Gonorrhoea	100,000	6/2/45	6/2/45	17/5/45	109	100
3	30	Syphilis	2,000,000	17/3/45	29/3/45	13/6/45	76	88
4	28	"	2,000,000	19/2/45	4/3/45	27/5/45	84	97
5	34	Gunshot wnd.	1,333,300	27/3/45	7/4/45	19/6/45	73	84
6	20	Syphilis	2,000,000	28/3/45	9/4/45	25/6/45	77	89
7	34	"	2,000,000	19/4/45	15/5/45	29/6/45	59	71
8	22	"	2,400,000	10/2/45	17/2/45	29/6/45	132	139
9	23	"	2,000,000	14/4/45	26/4/45	4/7/45	69	81
10	20	Gunshot wnd.	1,000,000	20/2/45	2/3/45	13/7/45	133	143
11	22	Gonorrhoea	100,000	14/12/44	15/12/44	15/7/45	212	213
12	23	Gonorrhoea, syphilis	100,000	3/5/45	4/5/45	3/8/45	34	92
13	21	Furunculosis	2,400,000	23/6/45	30/6/45	13/7/45	68	72
14	24	Gonorrhoea	480,000	2/5/45	6/5/45	10/8/45	83	84
15	23	"	100,000	1/5/45	2/5/45	24/7/45	100	101
16	35	"	100,000	1/5/45	2/5/45	10/8/45	109	116
17	26	Syphilis	2,400,000	22/3/45	29/3/45	25/5/45	74	75
18	23	Gonorrhoea	100,000	11/3/45	12/3/45	16/6/45	42	54
19	27	Syphilis	2,000,000	23/4/45	5/5/45	23/6/45	79	86
20	27	"	2,400,000	29/3/45	5/4/45	2/8/45	141	150
21	24	"	2,400,000	5/3/45	14/3/45	12/7/45	83	91
22	25	Gonorrhoea	2,400,000	12/4/45	20/4/45	19/6/45	154	155
23	31	"	100,000	15/1/45	16/1/45	16/8/45	104	104
24	32	"	100,000	4/5/45	4/5/45	18/8/45	133	135
25	26	Syphilis	140,000	5/4/45	7/4/45	30/8/45	83	95
26	28	"	2,000,000	27/5/45	9/6/45	31/8/45	83	95

In each of the above cases the penicillin was given by intramuscular injection at 3-hourly intervals. Gonorrhoea was usually treated with 5 injections of 20,000 units and syphilis with 100 injections of 20,000 units or 60 injections of 40,000 units.

Comment on the Cases

On questioning an unselected series of 100 patients in the medical wards of the hospital it was found that only 4 of these had been treated with penicillin in the previous 7 months, hence there can be no doubt that the high percentage of jaundiced patients that had been treated with this drug is of statistical significance.

So far as is at present known, penicillin has no toxic effects when used in therapeutic doses. Local pain at the site of injection, venous thrombosis (when the drug is administered intravenously), fever, and urticarial rashes are all occasionally met with, but are considered to be due to impurities. One patient of a further series, reported below, received a total of 23,220,000 units within 48 days without any toxic effects being produced.

Clinically these cases were indistinguishable from other forms of jaundice known to be transmissible—infective hepatitis and post-arsphenamine jaundice. If in fact the disease was conveyed by the penicillin injections the incubation period is closely comparable with that known in the above two types of jaundice. In the present series the incubation period is 34 to 213 days; in post-arsphenamine jaundice the incubation period is about 100 days. Cameron (1943), in his report on the experimental transmission of infective hepatitis to human volunteers by injection of blood or serum from jaundiced patients, stated that the incubation period varied from 30 days to 6 months. The unusually long latent period of 212 to 213 days in Case 11 suggests that the association of penicillin treatment with jaundice may have been coincidental. The most probable explanation is that post-penicillin and post-arsphenamine jaundice are identical, and due to an infective agent conveyed from patient to patient by the injections. This would explain the relative frequency of jaundice after the treatment of syphilis (15 cases) and gonorrhoea (9 cases). In a V.D. treatment centre in this area 135 cases of syphilis and 419 cases of gonorrhoea were treated in a period of 8 months. The higher incidence of jaundice in syphilitics may be explained by the much larger number of injections (either 60 or 100) given and so the much greater possibility of conveying the infection to the patient.

Cases of Jaundice occurring in a Penicillin Research Unit

This unit, which was attached to an Indian Base General Hospital, was investigating the effect of penicillin treatment on

chronic bone infections due to war wounds. The case treated in a ward of 80 beds, in which also cases of the type were being treated by the general surgeons. Many cases had had blood or plasma transfusions and injected penicillin before admission.

During the period of the outbreak 170 cases were in the ward, and 66 of these were given penicillin injected. 10 cases of jaundice occurred, 9 of them in patients who had penicillin since admission. The other—the first case series—had had penicillin at another medical unit two months previously. Table III gives further details of these cases.

TABLE III.—Clinical Details of Cases of Jaundice at a Penicillin Research Unit

Case No.	Date of Wound	Penicillin Given Before Admission		Date Admitted to Unit	Penicillin Given at Research Unit	
		Date Started	Dose (units)		Date Started	Dose (units)
1	18/11/44	21/11/44	950,000	26/1/45	9/2/45	23,220,000
2	3/8/44	—	0	14/8/44	6/9/44	840,000
					22/9/44	1,200,000
					2/1/45	3,220,000
3	16/3/44	—	—	3/5/44	4/1/45	2,340,000
					17/4/45	1,600,000
4	29/5/44	—	0	25/11/44	2/1/45	2,340,000

					24/3/45	1,440,000
8	16/1/45	16/1/45	300,000	26/1/45	1/2/45	2,340,000
					2/3/45	2,340,000
9	15/5/44	—	0	25/10/44	21/2/45	1,880,000
10	14/5/45	—	0	17/6/45	3/7/45	320,000

With the exception of Case 1, penicillin was given to the above patients in doses of 20,000 units 3-hourly by intramuscular injection while at the Research Unit.

In this small series of cases there was one fatality (Case 1). The patient was a male of 18 years who sustained machine bullet wounds of both legs and a compound fracture of right femur. On May 3, 1945, when convalescent from wounds, he developed infective hepatitis and malaria (Case 1). The latter condition responded to mepacrine treatment, the hepatitis progressed, and he died on May 17. At post-mortem examination extensive liver necrosis was found.

Discussion of Research Unit Cases

In a closed community of this type the possibility of spread by droplet or intestinal infection must always be considered, however, in view of the fact that jaundice was confined to one ward only, and in that ward to the penicillin-treated cases, spread by syringe infection seems a more likely explanation. In this ward great care was taken over the sterilization of needles and syringes. The dose of 20,000 units of penicillin was made up to a volume of 2 ml., a freshly sterilized needle was used to withdraw this from the ampoule, and a second needle to inject the drug into the patient. In some cases a freshly sterilized syringe was employed for each patient, but in some the same syringe was in use for several patients in succession. Needles and syringes were sterilized by boiling for 15 minutes; the needles were handled only with forceps.

It is difficult to attempt to trace the spread of the infection from patient to patient: first, because an unknown percentage of the cases of hepatitis remain non-icteric and undiagnosed; secondly, because the period during which the patient is infectious is still not known. Lisney (1944) states that the patient is infectious for at least one week before the appearance of the jaundice, while Sheehan claims that the patient becomes infectious about one month after the onset of the incubation period. McCallum and Bauer (1944) have succeeded in conveying homologous-serum jaundice to volunteers by injecting serum withdrawn on the seventh day of the jaundice.

If Case 2 was infected by injections in September, 1944, could have transmitted the disease to Cases 3, 4, and 7 means of the course of injections starting on Jan. 2; and Case 4 could have passed the disease on to Case 6 by means of a course starting on March 24. Again, if the patient still remains infectious as long as 14 days after the onset of jaundice, Case 1 may have transmitted the condition to Cases 5 and 10.

Syringe Contamination during Intramuscular Injection

While faulty technique of sterilization or injection might lead to syringe contamination it was felt that this could not be the usual explanation of these cases of jaundice and that the traditional method of giving a series of injections from one syringe (while using a fresh needle for each patient) might well be at fault. Further investigation confirmed this view and demonstrated the frequent presence of blood in the syringe after a single intramuscular injection had been given.

Red Blood Cells in the Syringe after Intramuscular Injection

As it was impossible to detect minute quantities of blood plasma with the apparatus available it was decided to concentrate on detecting red blood cells in the syringe contents after an intramuscular injection. The following technique was evolved.

The needle and syringe were filled with sterile normal saline (0.85% sodium chloride), the needle (with the syringe attached) was inserted into the quadriceps extensor cruris, and 1 ml. of saline was injected. The needle, with the syringe still attached, was then immediately withdrawn, the needle was removed, and succeeding drops of saline from the tip of the syringe were examined microscopically for red blood cells; these were counted in a Neubauer counting chamber.

The syringes used were of the standard Army pattern, 2 ml., 5 ml., and 10 ml. in size; the needles were the usual office sizes 19, 21, and 23 (Birmingham English standard wire gauge), with a length of 50 mm., 38 mm., and 25 mm. respectively. The apparatus was freshly autoclaved before each injection. The results obtained are summarized in Table IV.

TABLE IV.—Red Blood Cells found in the Syringe After an Intramuscular Injection

(A) Injections Given Into a Muscle in a State of Active Contraction

Syringe	Needle	Volume Injected	No. of Red Cells in 0.9 c.mm. of Saline			
			Drop 1	Drop 2	Drop 3	Drop 4
ml.	S.W.G.	ml.				
2	23	1	3	0

2	21	1	0		
2	21	1	0		
2	21	1	0		
2	21	1	0		
10	21	1	2	11	
10	21	1	0		

Thus contamination of the syringe with red blood cells had occurred in 17 out of a total of 39 injections. This statement, however, needs further comment. It will be noted from Table IV that the red cell count rapidly diminished with each succeeding drop; this suggests that the syringe contents generally are not contaminated, but that the contamination is

confined to the small drop of fluid on or in the nozzle of the syringe when the needle is removed. This fact was further confirmed by the following experiment. A series of five intramuscular injections of 1 ml. was given from the same 10-ml. syringe; drops of saline were examined microscopically until no further red cells were found, and then the remaining fluid in the syringe was ejected into a centrifuge tube and spun for 10 minutes. On examining the fluid from the bottom of the centrifuge tube only one or two red cells could be found. From the above results it is apparent that the frequency and severity of syringe contamination vary according to whether the muscle injected is relaxed or is in a state of active contraction. With the muscle contracted, contamination occurred in 15 out of a total of 27 injections and up to 243 red cells in 0.9 c.mm. of saline were counted; with the muscle relaxed, however, contamination occurred in only 2 out of a total of 12 injections and a maximum of 2 red cells in 0.9 c.mm. were found.

Experiments have shown three possible mechanisms which, either separately or together, might account for this contamination. These are: (a) back pressure, forcing fluid from the muscle into the needle; (b) spread of blood from the tip of the needle towards the syringe; and (c) suction when removing the needle from the syringe, aspirating the needle contents back on to the tip of the latter.

Back Pressure from the Muscle

For some time it has been recognized by the dental profession that, when injecting a local analgesic under pressure into the fibrous tissue of the gum, fluid is forced back and contaminates the syringe. Hence it is customary for dentists to use a clean syringe for each different part of the gum if any evidence of infection is present. Again, when giving an intramuscular injection with a small syringe it is not uncommon to note that the plunger returns for a short distance when the pressure is released at the end of the injection. To demonstrate this more accurately a series of 12 intramuscular injections of 1 ml. of normal saline were given into the contracted quadriceps by means of a 1-ml. vaccine syringe. In two instances fluid was noted to return, to approximately the volume of 0.02 and 0.04 ml.

Further experiments were carried out in which saline was injected intramuscularly, and immediately the injection was completed the needle was switched (by means of a two-way tap) to a manometer, which consisted of a 1-ml. micropipette graduated in hundredths of a milliliter. The results obtained are detailed in Table V.

TABLE V.—Return of Fluid from the Muscle After Injection

Volume of Fluid Injected (ml.)	Muscle Tone	Volume of Fluid Returned (mL)
0.5	Relaxed	0.0025
1.0	"	0
2.0	"	0.005
3.0	"	0.100
0.5	Contracted	0.045
1.0	"	0.010
2.0	"	0
0.5	"	0.010
1.0	"	0
2.0	"	0.035

Thus varying amounts of saline up to a maximum of 0.1 ml. were returned from the muscle into the manometer. These latter results, however, are open to criticism. In the first place, a certain rise of fluid level in a narrow-bore tube can be caused by the surface tension of the fluid.¹ Further experiments suggest that this may partly explain these results, but it is my opinion that this is not the whole explanation and that the return of fluid is in part due to the elasticity of the muscle. Secondly, the conditions of the experiment are not comparable with those existing when a routine injection is given and when returning fluid displaces the heavy plunger of a syringe; it seems possible (although it is not proved) that returning fluid can displace fluid through leaky joints in the syringe without moving the plunger at all.

Spread of Blood Along the Needle Towards the Syringe

If the tip of the needle is contaminated with blood the red cells gradually spread along the needle towards the syringe.

To demonstrate this the following technique was used. An all-glass 2-ml. syringe with a No. 23 needle attached was filled with normal saline and a tiny drop of citrated blood (as used for estimation of sedimentation rate by the Westergren method) was placed on the tip of the needle by means of a Pasteur pipette. After an interval varying from 15 to 60 seconds the needle was cut off at the socket with wire-cutters, the socket removed from the syringe, and the drop of saline on the tip of the syringe examined for red cells. It was found that contamination could occur in 45 seconds, as the results shown in Table VI demonstrate.

TABLE VI.—*Spread of Red Cells Along the Needle Towards the Syringe*

Time Interval between Application of Red Cells and Cutting the Needle	No. of Red Cells in 0.9 c.mm. of Saline in Drop at Tip of Syringe				
	Expt. 1	Expt. 2	Expt. 3	Expt. 4	Expt. 5
15 secs.	0	0	0	0	0
30 "	0	0	0	0	0
45 "	0	4,608	396	0	0
60 "	780	0	0	13,392	13,392

Aspiration of Contents of Needle when it is Removed from the Syringe

That this actually occurs can be very simply demonstrated. A syringe with needle attached is filled with fluid and the plunger pressed until a small drop of fluid appears at the tip of the needle; if the needle is then removed from the syringe the drop is immediately sucked back.

Gross contamination of the syringe by this mechanism was demonstrated with a similar method. The syringe, with the needle attached, was filled with normal saline and a tiny drop of citrated blood was placed on the needle-tip; the needle was then removed from the syringe and the drop of saline at the tip of the syringe was examined for red cells. Contamination resulted, as can be seen in Table VII.

TABLE VII.—*Aspiration of Needle Contents on Removal from Syringe*

Size of Needle	No. of Red Cells in 0.9 c.mm. of Saline in Drop at Tip of Syringe		
	Experiment 1	Experiment 2	Experiment 3
23	105	Too numerous to count	Too numerous to count
21	Too numerous to count	14,544	" "
19	70,560	26,784	" "

Further experiments, which it is unnecessary to detail here, have shown that the amount of fluid which can be aspirated by this means may be as large as 0.1 ml.; this is more than the internal volume of the needles used. Hence it is probable that when the needle is removed from the syringe the whole of the contents of the needle (but not of the socket) are aspirated and replaced by air.

Discussion on Syringe Contamination

From the above experiments it is clear that in a high proportion of cases a syringe is contaminated after a single intramuscular injection of 1 ml. has been given. The limited number of investigations carried out suggests that contamination occurs as follows. A small amount of fluid is forced back into the needle after the injection, or traces of blood are left on the tip of the needle when it is withdrawn; this blood tends to spread slowly along the needle, and on removing the latter from the syringe the needle contents are aspirated, leaving a contaminated drop of fluid on the tip of the syringe. This drop contaminates the next injection despite the changing of the needle. It seems possible that in exceptional circumstances (and particularly when a large quantity is injected) fluid is actually forced from the muscle into the syringe and directly contaminates the syringe contents.

Summary

A series of cases of jaundice following penicillin treatment is reported. It is considered that this condition is transmitted from patient to patient by means of contaminated syringes.

Experiments are described which show that a single intramuscular injection of 1 ml. of fluid may lead to contamination of the

syringe used. The mechanism by which this contamination occurs is discussed.

I wish to thank Cols. W. C. MacKinnon and G. S. Douglas, and Lieut.-Cols. A. C. G. Gairdner and H. R. S. Harley, R.A.M.C., for permission to publish details of the cases reported in this paper.

PYOGENIC OSTEOMYELITIS OF THE SPINE

BY

PETER MARTIN, M.Chir.
Chelmsford and Essex Hospital

Although pyogenic osteomyelitis of the spine is generally considered to be a rare and fatal disease, a perusal of the literature and a more ready appreciation of the possibility of the condition lead to the conclusion that it is considerably more common than was originally thought and that it is by no means so far as has been considered. Wilensky (1934) and Kulowski (1938) in the United States have described the condition well, and Turner (1938) in this country has added to our knowledge. It is agreed that osteomyelitis of the spine, forming part of generalized bacteraemia, has been almost invariably fatal, and Butler *et al.* report a mortality of 100% in 13 cases, all occurring in children and young adults. It may be that penicillin will brighten this gloomy picture.

These cases are often so acute and fulminating that an antemortem diagnosis is not made owing to the intense toxæmia of the patients; the more hopeful variety of the disease is that where the pathology is limited to one or other region of the spine, and in these cases the mortality rate is somewhere in the region of 25%. There is reason to suppose that cases labelled tuberculosis of the spine, which do so well with an early firm bony fusion, are in reality cases of pyogenic osteomyelitis, will be discussed later, and when these cases are recognized may be that the mortality is even lower.

The disease is approximately three times more common in males than in females, and the age of onset is predominant in the third decade—that is, after the vertebrae are fully formed—thereby differentiating it from osteomyelitis occurring in long bones. This age incidence is no doubt due partly to the fact that there is no true epiphyseal growth in the vertebral bodies and partly to the presence of a cellular bone marrow with sluggish blood flow, thereby encouraging embolism and thrombosis in pyæmic states. Such a condition of bone and blood flow is normally present in the metaphyseal areas of long bones thus accounting for the more usual incidence of osteomyelitis in these bones in adolescence.

Aetiology and Pathology

The influence of trauma as an aetiological factor is doubtful and in Kulowski's series of 102 cases there was a history of trauma in 30%. In the present series Case 4 appears to date from a fall, and Case 3 is of interest as occurring after a lumbar puncture, whether or not that was a factor; but in the remainder there does not appear to have been any injury.

The lumbar region is most frequently involved, and the bodies of the vertebrae are generally affected, usually as a metastatic phenomenon, the primary focus being recognizable in about half the cases as a topical infection such as a boil, whitlow, tooth infection, septic wound, or another focus of osteomyelitis, and the causative organism, if it can be obtained either directly or by blood culture or from the primary focus, is a *Staph. aureus*, less commonly *albus*, or rarely a streptococcus. Direct infection can of course occur.

Pyogenic infection in the early stages gives rise to an abscessing lesion showing a liability to spread to adjacent segments.

This is due to the fact that the vertebral bodies lack a compact outer layer, thus allowing the intervertebral disk early to become subjected to the suppurative process; and the disk substance is rapidly and extensively destroyed by the action of the proteolytic enzymes of the pyogenic exudate and the adjacent body is directly infected. In tuberculous infection, however, the disk substance is not so readily destroyed, and, as it has no vascular or lymphatic connexion with the vertebral bodies bounding it, it offers a formidable barrier to the spread of the disease. For tuberculous infection to attack adjacent segments the process must spread under the anterior common ligament, whence it reaches neighbouring vertebrae by way of their anterior surfaces, and considerable remnants of disk substance may remain after destruction of adjacent segments by disease (Fig. 1).

FIG. 1.—Tuberculous disease of spine. Showing comparative persistence of intervertebral disk, collapse of the vertebra below and rarefaction of the bone of the anterior aspect of the vertebra above, and spread of disease anteriorly to, rather than through, the disk.

Radiologically these changes are of value in the differential diagnosis, as in pyogenic osteomyelitis early narrowing or disappearance of the intervertebral space is evident. Narrowing of the space is also seen in tuberculous disease, and in this case is due to disease-softened osseous or ligamentous tissue allowing the semifluid nucleus pulposus to prolapse into the vertebral bodies above and below, and is neither so early nor so marked a feature as in pyogenic infections. The abundant blood supply, with a local excess of calcium, results in early and massive new bone formation, giving rise at first to a "beaking" of the lower and upper margins of adjacent vertebral bodies, and later to a fusion of adjacent vertebrae by means of these bony outgrowths. Similarly the free blood supply and the cancellous nature of the bone rarely give rise to the formation of sequestra of such a size that they are not readily absorbed. This subperiosteal new bone formation, occurring often within a few months of the onset of the disease, is the exact antithesis of the pathology of tuberculosis of bone, where the essential lesion is destructive and where new bone formation and bony fusion hardly occur. In pyogenic osteomyelitis collapse of the bodies and gibbus formation are not common, as the severity of the symptoms leads to the patient's taking to his bed at an early stage of the disease. Suppuration is common and abscess formation often occurs, sometimes leading to the formation of large abscess cavities, which generally enlarge forwards and are guided in their course

usually by normal cleavage planes. Thus in the cervical region retropharyngeal abscesses may result; in the thoracic region posterior mediastinal abscesses, which may perforate pleural or pericardial cavities; in the lumbar region psoas or perinephric abscesses, and in the sacral region pelvic or perirectal abscesses, may be seen; and sinus formation is not an uncommon complication. Occasionally large abscesses form where the bone focus is minimal in extent and not detectable on x-ray examination. Unusually an epidural abscess occurs, and this results in compression, meningitis, or vascular disturbance in the cord, with a mortality rate of 50%. The onset of spinal symptoms in pyogenic osteomyelitis is sudden and dramatic compared with the slow and gradual appearance of similar symptoms in tuberculous disease, except in those rare cases in the latter condition where paraplegia has a sudden onset due to bone displacement. It is interesting to note that Browder and Meyers (1941) considered that 10 out of 14 cases of epidural abscess resulted as a direct spread from an osteomyelitis of the spine.

Signs and Symptoms

Clinically the onset is often acute, but sometimes subacute or insidious; in very acute cases the local signs may be overridden by the intensity of the toxæmia. Spontaneous intense lumbar pain, often diagnosed as lumbago or fibrositis, which is diffuse at first and later localized, is always present, and is usually of sufficient severity to confine the patient to bed, and often severe enough to render him helpless, fixed, and unable to move. It is accompanied by a marked degree of spasm of the erector spinae, and all movements of the spine are markedly limited and painful. Localized tenderness appears later owing to the original depth of the lesion, but once apparent it is very persistent. Should the disease attack the posterior processes, oedema and tenderness of the back muscles, and later abscess formation deep to or within these tissues, may occur. In the early stages a blood culture may be positive and the primary focus may be seen. Pyrexia and leucocytosis are present in varying degrees, but signs of an acute and severe systemic upset are often not prominent. An increasing leucocyte count indicates progress to abscess formation. When the bone focus is minimal an abscess may present clinically, and in cases of obscure, deep-seated pus pyogenic osteomyelitis of the spine should be considered. Where a sinus is present, injection of scrapings into a guinea-pig is of value in the differentiation of pyogenic from tuberculous osteomyelitis, or a secondarily infected tuberculous disease from an osteomyelitis of pyogenic origin. When the disease process is rapidly limited by the natural defences of the body—which, fortunately, is generally the case—the early tendency to a firm bony union is seen on x-ray examination, and may occur two to three months after the onset of the disease.

Diagnosis

The radiological findings are of great importance in the diagnosis of the condition, although in the fulminating cases no changes will be seen, as these have not had time to develop before a fatal outcome; and in some cases where the bone focus is minimal in extent they may never be evident (Case 1). When the disease attacks the body it may be two to three months before changes are seen on x-ray examination. The first sign is a narrowing of the intervertebral space, with a moth-eaten irregularity of the bodies bounding it. At the same time there is an increased density of the affected vertebrae, sometimes with areas of mottled rarefaction, in contrast to the generalized decalcification evident in early tuberculosis. At about the same time, or shortly afterwards, subperiosteal new bone is formed at the margins of contiguous vertebrae, leading to a beaking which continues to increase in size; these eventually fuse together, resulting in a bony ankylosis. This process is complete at a relatively early date, and in one case was seen seven months after the onset of symptoms in spite of incomplete immobilization in this particular instance.

The diagnosis in the early stages of the disease rests on the severe backache accompanied by pyrexia and a leucocytosis and possibly by rigors. In a number of cases there is a history of a primary focus of infection. Diagnosis is often not completely clear until a later stage, when x-ray changes become apparent. The differential diagnosis of the subacute or chronic

form from tuberculosis of the spine may present difficulties, but the following points should decide without any great doubt.

	Pyogenic Osteomyelitis	Tuberculous Osteomyelitis
Site of disease	Body usually, often appendages	Body almost invariably
Primary focus	Topical pyogenic infection present in 50%	Other tuberculous focus often detectable
Onset	Usually very sudden; sometimes gradual	Gradual
Pyrexia	Variable, often marked	Variable, seldom marked
Pain	Usually intense	Persistent aching
Leucocytosis	May be marked	Not a feature
Vertebral collapse	None	Usual
X-ray findings	Increased density. Subperiosteal new bone formation. Spread through intervertebral disk	Decreased density. No new bone formation. Spread via anterior surface of bodies
Cord involvement	Rare and acute onset	Common and gradual onset
Course	Short to bony fusion	Prolonged to recalcification and fibrous fusion

Treatment

The treatment of the condition consists in immobilization of the spine, preferably in a plaster bed, until the disease process is over and bony fusion is complete. Abscesses, if they form, should be evacuated with scrupulous attention to the prevention of secondary infection, and penicillin both locally and systemically plays an important part in the treatment. Fusion of the affected vertebrae by means of an Albee graft has been suggested, but this is not necessary, as new bone formation leading to bony ankylosis between adjacent diseased vertebrae is an early and constant feature.

Illustrative Cases

Case 1.—A child aged 4 was admitted with a history of being off colour for five days and complaining of a pain in his back. He showed signs of meningitis and there was intense spasm of the lumbar muscles. His C.S.F. contained pus and *Staph. aureus*. Laminectomy of the third and fourth lumbar vertebrae was done, and an abscess was found arising in the body of the third lumbar vertebra and perforating the dura. The arachnoid was intact. The abscess was evacuated; 30,000 units of penicillin were

FIG. 2.—Skiagram of Case 2 three months after the onset of backache, showing narrowing of the intervertebral space, moth-eaten irregularities of the bodies bounding the space, and generalized increased density.

instilled, and a further 60,000 units were injected into the ventricle. The patient made a complete recovery, but at no time were there any x-ray changes.

Case 2.—A man aged 54, on getting out of bed for the first time after treatment for multiple abscesses, experienced a sudden intense pain in the back. This pain confined him to bed, during which time

FIG. 3.—Skiagram of the same case 14 months after the onset of backache, showing firm bony union between beaks of affected vertebrae.

he showed a moderate fever with pyrexia up to 102° F. (38.9° C.). He was treated by recumbency, and three months later changes were apparent on x-ray examination (Fig. 2). Five months after the onset of symptoms subperiosteal new bone and beaking were seen, and he was allowed up in a plaster jacket. Bony fusion became apparent 14 months after the onset; this afterwards enlarged and strengthened (Fig. 3), and three months later he discarded all fixation and was symptomless, apart from stiffness of the lumbar spine.

Case 3.—A naval officer aged 32 developed pyaemic cellulitis of each arm following an osteomyelitis of the skull complicating a shrapnel wound. Sequestrectomy was done and the patient became symptomless. A lumbar puncture was performed to investigate the condition of the C.S.F. as a result of the head injury. Two months after this he developed a severe backache, with fever and a slight leucocytosis. He was treated in recumbency, and three months after the onset of backache x-ray examination showed signs of pyogenic osteomyelitis. The condition progressed satisfactorily and a sound bony ankylosis resulted (Fig. 4).

In this case a possible contributory factor is the lumbar puncture, causing a local lesion in the disk or adjacent bone, and leading to a focus of diminished resistance to infection. Alternatively the focus of disease and the lumbar puncture may have been coincidental.

Case 4.—A naval rating, aged 32, ten days after a fall down a pile of bombs developed an intense pain in the lumbar region of the spine. For the next three to four weeks he had a slight fever, the temperature rising to 102° F. (38.9° C.), with occasional rigors and a white cell count of 17,000. A month after the onset of the pain an upper premolar tooth was extracted, and pus containing a staphylococcus was obtained from the socket. He was treated in recumbency, and nine months from the onset firm bony fusion was seen on x-ray examination. He returned to full duty six months later.

In this case it is reasonable to suppose that the fall caused vascular damage in the body of the third lumbar vertebrae

ing up a local focus where staphylococci from the infected th socket lodged.

Case 5.—A naval rating aged 25 was admitted to hospital because a sinus of the posterior chest wall following the incision of an abscess at this site eight months previously. A skiagram showed increased density of the left side of the bodies of the third and fourth thoracic vertebrae, and the intervertebral space between these was narrowed. An oblique view showed beak formation of the

FIG. 4.—Lateral view in Case 3 seven months after the onset of backache, showing massive bony bridging.

lower border of the third dorsal vertebra. The adjacent heads and necks of the third and fourth ribs showed widening and irregular thickening, and a similar appearance was evident in the corresponding inverse processes. Examination of the pus from the sinus indicated a mixed staphylococcal and streptococcal infection, and biopsy of the sinus wall showed no evidence of tuberculous anastomosis.

The records of this case are incomplete, but according to the patient he was feverish at the time of the dorsal backache. The x-ray appearances point to a pyogenic infection, although an original tuberculous infection with a secondary pyogenic infection cannot be ruled out. It is in such a case that inoculation of a guinea-pig with sinus scrapings would be valuable, but this was not done owing to the patient's repatriation to Canada.

Summary

The aetiology, pathology, clinical signs and symptoms, and treatment of pyogenic osteomyelitis of the spine are described.

It is suggested that the disease is more common than has been thought.

It seems that many cases of osteomyelitis of the spine, labelled tuberculous, are in reality pyogenic in origin.

At least in adults the disease is less fatal than has been considered.

The notes of five cases are presented.

TREATMENT OF OSTEOARTHRITIS BY LACTIC ACID INJECTION

A SERIES OF 26 CONSECUTIVE CASES IN GENERAL PRACTICE

BY

R. MAWSON, M.R.C.S., L.R.C.P.

Stimulated by the work of Grant Waugh on intra-articular injection of lactic acid with procaine into the hip we recently gave his treatment to a series of 26 patients. The series comprised 6 cases of arthritis of the hip, 18 of the knee, 2 of the wrist, and consisted of the following types: osteoarthritis of the elderly; post-traumatic; so-called "menopausal"; post-infective; and residual deformity stage of rheumatoid arthritis. The cases occurred in semirural general practice and were taken from all social strata in our valley community. Economic factors prevented serial radiographs and periodic estimation of the erythrocyte sedimentation rate, and the treatment was domiciliary in all instances but one.

Case records were kept as simple as possible, and notes of progress consisted of statements made by the patient and his relatives, together with my own observations. It was difficult always to assess evidence of progress or deterioration in objective terms except when the patient showed dramatically changed physical signs—e.g., doubled range of movement at the affected joint. A guide to progress in this disease is the distance that can be walked before and after treatment. This criterion was used in most cases. However, clinical medicine in general practice includes sundry observations of patients in the street, in shops, in the village dance hall, and in the public house. I should be more pleased to see an osteoarthritic at the end of a fish queue than a small change in her sedimentation rate. Grant Waugh's assessment of progress was based on the degree of overall disability, expressed as a percentage, taking 90 to 100% disabled to describe patients confined to bed, and 70 to 80% for those able to walk with considerable difficulty.

It is not easy to classify stages of recovery. So often psychological factors distort the clinical picture. It is well known that all forms of rheumatism and neurosis are often closely related, but it is not desirable here to add to the boresome flavour of some of the observations made by certain workers in this field: "The cramped muscle reflects the cramped mind" is an illustration. Reference will be made subsequently to certain features of anxiety which obscure the slighter signs of recovery in this type of patient.

The clinical state before and after treatment was based on inquiry into the following: pain and tenderness; deformity and posture; anorexia and insomnia; maximum walking distance; stiffness and alteration of gait; effusion; mental distress.

Below are given a table showing results of treatment in the series of 26 and records of four typical cases.

Joints Affected	No. of Cases		Age Range	Av. No. of Injections	Results		
	M.	F.			Better	No Change	Worse
Hips ..	4	2	36-67	4	5	1	0
Knees ..	1	17	42-73	4	17	1	0
Wrists ..	0	2	—	2	1	1	0

Case Histories

Case 1.—Mr. D., a landworker aged 36, had suffered from osteoarthritis of the left hip for 7 years, the result of a fractured femoral neck in 1927 (4 months in plaster). His symptoms were pain, stiffness, and insomnia. Examination revealed quadriceps and gluteal wasting, concealed hip flexion, flexion 60°, extension nil, adduction and abduction very small, rotation nil. All movements were painful. Walking distance before treatment: 1/4 mile. (400 metres) in great pain. He was on the point of giving up his employment. Treatment consisted of four injections. The first injection brought a dramatic improvement; the patient could not only walk easily, but was actually able to run—something he had not been able to attempt for several years. The third and fourth injections produced much pain, and work stopped for 10 weeks. He is now back at work, and can walk up to 4 to 5 miles (6.5 to 8 km.) a day. There is still pain in the joint, but he can tie his left shoe-lace. All movements have increased, particularly flexion—almost to 90°. There is no concealed hip flexion. A radiograph

FIG. 1.—Radiograph of Case 1, Feb. 14, 1946.

(Fig. 1) taken on Feb. 14, 1946, reveals loss of spacing, flattening of the head of the femur, sclerosis and broadening of the neck with buttress formation, suggesting an old injury to the neck of the femur and now showing changes of osteoarthritis. From the appearance this buttress should interfere with the movement of

FIG. 2.—Radiograph of Case 1 taken on March 21, 1946.

the hip-joint. It is not quite clear whether the buttress has fused with the lower part of the acetabulum. Fig. 2 shows the condition on March 21, 1946.

Case 2.—Miss P., a housekeeper aged 63, had her hips, knees, and wrists affected during a period of 9 years, the cause being rheumatoid arthritis. She had great pain, particularly in the right knee; and knee movements were almost nil. She suffered from loss of sleep and appetite, and had been taking eight aspirins daily. She could only hobble around with the aid of two sticks, and had not been outside the house for months. She received two injections in the right knee, which was manipulated under pentothal. There is now almost complete loss of pain in the knee, which shows greatly increased movement. She can carry a loaded tea-tray upstairs, and she can walk half a mile (800 metres) to the post office with the aid of a stick. Her general state—colour, appetite, mental outlook—is very much improved. She is almost weaned from salicylates.

Case 3.—Mr. W., a gardener aged 65, had his right hip-joint affected for 8 years. His symptoms before treatment were pain (which made him give up work), stiffness and diminished movement, and he could walk only about 200 yards. He was given two injections. Increased movements at the right hip resulted and there was far less pain. He resumed work after the second injection. Since then (March, 1946) he has worked 8 to 9 hours a day and is able to attend to his own garden in the evening.

Case 4.—Mrs. B., a housewife aged 69, had the shoulders, wrists, and small joints of the hands affected, especially the left wrist. The symptoms were pain, anorexia, insomnia, immobility of wrists, and wasting of the small muscles of the hands. She was unable to feed herself through inability to grip knife and fork. Her bed had been put downstairs because she could not manage the stairs. Her walking distance before treatment was nil. The patient received two injections in the left wrist. Movements at that joint began a few days after the first injection. She can now flex to 70° and dorsiflex 30°, and there is no pain or swelling. Her grip has improved, and she can feed herself and get upstairs.

Technique

From 15 to 20 ml. of a stable solution of 0.2% lactic acid with procaine, having a hydrogen-ion concentration of 5.2, is injected into and around the hip-joint on each occasion. A similar amount may be injected into the knee-joint, but the wrist-joint will only take amounts varying from 2 to 5 ml. Skin sterilization is effected by 1% "cetavlon" or 1:1,000 acriflavine. Skin, subcutis, muscle, and joint capsule are infiltrated with "novutox," the average amount required being 20 ml.; it is greatest in the case of the hip-joint in obese patients, and smallest in injection of the wrist. For the hip-joint a 6-in. (15 cm.) Record needle with wide bore and of high tensile strength is employed. For the other joints sturdy intramuscular needles will suffice.

Approach to the hip-joint is made by two methods. (i) **Anterior:** The needle is inserted midway between the great trochanter and the intersection of the femoral artery with Poupart's ligament; it is directed upwards, parallel with the femoral neck, inwards and backwards. (ii) **Posterior (Fig. 3):** The needle is inserted at a point just posterior to the great trochanter, and in an upward, inward, and forward direction.

In dealing with the knee-joint the needle is inserted 1 in. (2.5 cm.) to the outer side of the patella (Fig. 4).

Approach to the wrist-joint (Fig. 5) may be carried out either (i) immediately distal to the tip of the ulnar styloid process between flexor and extensor carpi ulnaris tendons, or (ii) dorsally between tendons of extensor pollicis longus and extensor indicis.

Miscellaneous Observations.—An intra-articular injection of the hip-joint requires a strong needle with a sharp short bevel, as the capsule in chronic cases of osteoarthritis may be up to 1/2 in. (1.25 cm.) in thickness. The needle must be inserted slowly without undue force. Once inside the joint the solution will run in easily. If much pressure is necessary the fibres of the capsule are probably outside the joint cavity embedded in the more pressure than usual), and this pain increased as the effect of the procaine diminished. Pain of a deep boring character persisted for several days and required the administration of the stronger barbiturates during that time. The thigh was held in the position of rest—internal rotation, semi-flexion, and adduction. After the intra-articular injection the patient is asked to put the joint through all its movements by himself.

Usually it is found that there is an immediate loss of local discomfort after the injection. Gentle passive manipulation of the joint follows the patient's own active movements. For the next 48 hours the patient is advised to remain in bed so that the joint shall not suffer weight-bearing. If the services of a physiotherapist are available the wasted muscles around the joint and elsewhere can be treated. A second injection is given after 7 days, following exactly the same plan as before. Subsequent injections, up to 6, are given if needed.

Manipulation under "Pentothal" Anaesthesia

In certain cases (from whose aetiology tuberculosis can with certainty be excluded) it may be necessary to manipulate the stiff painful joint under pentothal. This procedure was found to be followed by some pain and anxiety. The former responded to salicylates only, and was of short duration. The anxiety

FIG. 3.
Posterior approach to the hip-joint.

FIG. 4.
Approach to the knee-joint.

FIG. 5.
Approach to the wrist-joint.

has its origin in the belief—so commonly held by the chronic arthritic—that the affected joint will never move freely again. The patient's return to consciousness is awaited and the joint manipulated and flexed to its fullest extent, so that on opening his eyes the patient sees the degree of angulation possible in his joint. Quadriceps weakness makes it impossible for the patient to flex the hip completely at this stage, but there is always an improvement on the original degree of movement. Quadriceps drill, patient masseur, and encouragement from the family will do the rest.

Stages of Recovery

The first symptom to disappear is pain, followed by a changed mental outlook. To patients who previously were lethargic and pessimistic new hope is given. Sleep and appetite improve. As atrophied muscles are stimulated by massage the patient

ventures to do more about the house, and gradually leave is taken of the bedroom. The difficulty of stairs is overcome, and provided progress is maintained the patient is soon in the garden. Fresh air and exercise enhance the sense of well-being, which in turn promotes recovery of the local condition.

Summary

A series of 26 cases of mixed forms of arthritis is reviewed after treatment by intra-articular acid injection. The technique of injection of hip, knee, and wrist is described.

Of the patients, 6 were wage-earners. Recovery was sufficient in all six to enable them to return to their previous employment.

Of the remaining 20, mostly housewives, 18 were able to resume or do much more housework, with considerable relief of symptoms. Of the other 2 cases, one declined to have more than one injection, for domestic reasons; the other, with active rheumatoid arthritis of the wrists, showed no improvement.

DISAPPEARANCE OF SECONDARY SARCOMATOUS DEPOSITS IN THE LUNGS AFTER STILBOESTROL THERAPY

BY

J. GUNN ROBERTS, M.B., Ch.B.

Assistant, Surgical Unit, Welsh National School of Medicine

The beneficial effects of stilboestrol in the treatment of carcinoma of the prostate are well known, where not only the primary growth but also secondary growths in lung and bone have been kept under control and in several instances have disappeared completely. Less permanent and less dramatic effects have been observed in several cases of carcinoma of the breast treated similarly. Few successes have been claimed in any other type of growth.

In this communication a case of malignant endothelioma is recorded where secondary growths in the lung disappeared radiologically after stilboestrol therapy and where the patient was apparently free of active tumour two years later.

FIG. 1.—Skiagram of chest (June, 1944) showing multiple secondaries in both lung fields.

Case History

A married woman aged 25 was admitted on Oct. 15, 1942, to the wards of the Surgical Unit with a swelling of the left shoulder region of five months' duration. The swelling was situated on the anterior aspect of the shoulder and was obviously attached to the deep surface of the deltoid muscle. Its edges were well defined and it was tender. There was no limitation of the movements of the joint. X-ray photographs of the shoulder and chest showed no obvious radiological abnormality. On the 23rd an exploratory incision was made over the tumour and a large infiltrating growth was found deep to the deltoid muscle; it was adherent to the periosteum of the humerus and extended upwards to the capsule of the shoulder-joint, from which it obviously had its origin. Most of the tumour was removed. Histologically it was diagnosed as a malignant endothelioma (Prof. J. B. Duguid). Because of the nature of the growth a fore-quarter amputation was carried out on Nov. 5.

The patient made a good recovery and was in excellent health until June, 1944, when she began to have severe chest pain; a cough developed and she started to lose weight rapidly. When seen a few weeks later she was obviously cachectic, had lost 2 stone (12.7 kg.) in weight, and was no longer able to carry out her household duties. An x-ray photograph of the chest showed extensive secondaries in both lung fields (Fig. 1). As a palliative measure stilboestrol therapy was recommended. She was given bi-weekly injections for several months by her own doctor, and later had a small maintenance dose by mouth; the exact dosage is not known.

She did not report to the follow-up clinic till November, 1945. By then her general condition was much improved; her cough, lassitude, and chest pains had completely gone and she had made good her previous loss of weight. A skiagram now showed the complete disappearance of the lung secondaries (Fig. 2). When last seen by

FIG. 2.—X-ray photograph eighteen months later, showing complete radiological disappearance of the secondaries after stilboestrol therapy.

on July 15, 1945, 3 years 9 months after her amputation and years 1 month after the institution of stilboestrol therapy, the patient was in excellent health and was without symptoms. X-ray examination still showed both lung fields clear of metastases.

I am indebted to Dr. J. B. Duguid, professor of pathology at the Welsh National School of Medicine, for the histological report.

With the signing by the President of the United States of the Hospital Survey and Construction Act, an appropriation of 375 million dollars is authorized during the next five years for the provision of hospitals and health centres. Three million dollars is also authorized for State-conducted surveys of need. These must be made preliminary to the granting of Federal funds for construction. The Act provides latitude for each State to develop its own programme of hospital and health centre construction, to be administered by State authorities under standards specified by the U.S. Public Health Service. The Surgeon-General will be assisted in establishing standards by a newly created Federal Hospital Council consisting of eight members to be appointed by the Federal Security Administrator.

Medical Memoranda

Subacromial Dislocation of Shoulder

In view of the rarity of posterior dislocation of the shoulder the following case is considered worthy of description.

CASE REPORT

The patient, a frail but active old lady of 88, was referred to hospital by her doctor, with a diagnosis of posterior dislocation of the left shoulder. The history was that she had slipped while cooking supper, and, being unable to put out her arm in time to save herself, she received the full force of the fall on the anterior aspect of the left shoulder with the forearm held across the body.

On examination the left arm was fully adducted and medial rotated, the forearm being held across the chest and supported by the opposite hand. The history was that she had slipped while cooking supper, and, being unable to put out her arm in time to save herself, she received the full force of the fall on the anterior aspect of the left shoulder with the forearm held across the body.

X-ray examination was carried out in the antero-posterior and lateral planes, and the presence of a posterior dislocation of the shoulder was confirmed. The radiologist's report (Dr. J. D. Brown) was as follows: "Left shoulder. Subacromial dislocation of the humerus. The head of the humerus is displaced upwards and rotated medially, and the neck rests on the posterior rim of the glenoid fossa, nearly the whole of which is uncovered. The conoid tubercle of the clavicle is much enlarged, and there is a false articulation between it and the coracoid process. The conoid ligament is ruptured, and these articular surfaces have separated, the scapula being displaced downwards and rotated, the inferior angle moving laterally."

Reduction by Kocher's method was accomplished without difficulty under gas-and-oxygen anaesthesia. The head of the humerus appeared to re-enter the glenoid fossa at the end of the first movement. The arm was immobilized in a sling for two days, then the sling was discarded and active shoulder movements were started. When seen again one month later the patient had a full range of movement in the left shoulder; she volunteered the information that this shoulder was better than the right one, which was the seat of rheumatism. In the radiographs taken after reduction osteoarthritic changes were seen in the acromio-clavicular and shoulder joint.

DISCUSSION

The rarity of this lesion is emphasized by the fact that no reference to a case could be found in the British literature of the past fifteen years. The present case is unusual in that, owing to the thin atrophic nature of the tissues, the diagnosis was obvious on clinical examination. Again, contrary to the usual finding, there was no difficulty in recognizing the displacement in the antero-posterior radiograph. This was probably due to the large area of the glenoid which was uncovered. Rendich and Poppel (1941) emphasized that clinical diagnosis is difficult, and that posterior dislocation is nearly always missed in the antero-posterior view. This view in the above case confirms their findings that in subacromial dislocation the lesser tuberosity forms the extreme medial profile at the posterior lip of the glenoid fossa, with the head of the humerus directed posteriorly and medially. This appearance may be simulated by a normal shoulder in full medial rotation, but the head of the humerus is directed backwards and laterally, and it is the greater tuberosity which forms the extreme medial profile.

In a similar case described by Patel and Chorton (1941-2) a man of 44 fell from a bicycle on to the anterior aspect of the left shoulder. This case was reduced by traction in abduction followed by adduction. Thomas (1937) emphasized the frequent association of posterior dislocation with fracture of the tuberosities or neck of the humerus, and also its occurrence during epileptic or other convulsions. He encountered only four cases in over 6,000 shoulder examinations. May (1943) reported on three cases treated by the Nicola operation. The first occurred in an epileptic and remained undiagnosed for eleven months; the second was a recurrent posterior dislocation; and in the third, operation was indicated because closed reduction proved unstable.

The common mode of production is backward and outward pressure on the head of the humerus, either direct or through the elbow, combined with adduction of the limb across the chest and medial rotation. Rendich and Poppel produced the lesion in the cadaver by forced medial rotation. In the present case the osteoarthritic changes in the shoulder may have played a part, through atrophy of the labrum glenoidale.

In cases which are not diagnosed, a new fossa forms behind the glenoid, and this false joint is compatible with a surprisingly good functional result. Failure to diagnose the lesion may be due to a misleading history or the presence of an associated fracture which may seem to account entirely for the symptoms.

SUMMARY

case of subacromial dislocation of the humerus is described in which, contrary to the usual finding, both clinical and radiological diagnosis presented no difficulty. Kocher's method was used to correct the deformity, and a good functional result was obtained. It was suggested that osteo-arthritis changes may have been an aetiological factor in this case. The condition should be borne in mind in cases of injury to the shoulder in which radiological diagnosis appears to be negative.

I wish to thank Mr. M. R. Ewing for permission to publish the case and for his help in preparing this article.

Double Gastric Ulcer with Perforation and Haemorrhage

Double gastric ulcer with perforation and haemorrhage are the most common of the complications of peptic ulceration, rarely do both occur simultaneously, or at an interval of some days, in a case of gastric ulcer. More rarely, two ulcers may coexist, one of which perforates and the other is the seat of the haemorrhage. Such an event one ulcer is in the stomach, the other in the duodenum. The interest in the following case lies in the fact that two separate ulcers were present in the stomach; one perforated and the other gave rise to a rapid and fatal haemorrhage.

CASE REPORT

A man aged 55 was admitted to Lewisham Hospital on Oct. 12, 1946, complaining of acute upper abdominal pain of four hours' duration. The pain "doubled" him up, and it was not relieved by "powder." Although he felt nauseated he did not vomit. He gave a history of "dyspepsia" two to three hours after meals, of many years' standing; he consumed large quantities of alcohol.

On examination he was found to be a well-built man with a low complexion. Temperature 97° F. (36.1° C.), pulse 96, respirations 22. Urine contained a trace of albumin. His abdomen was very tender and rigid in all quadrants, and a diagnosis of perforated gastric ulcer was made. At operation a fairly large pre-pyloric ulcer was found situated on the lesser curvature, with a small perforation. There was a small quantity of free gastric contents present in the peritoneal cavity. The perforation was closed in the usual manner, utilizing an omental graft, and the abdomen closed without drainage. On Oct. 18 he vomited 1/2 oz. (14 ml.) bright-red blood at 15 p.m. At 10 p.m., while using the bed-pan, he had a large haematemesis and collapsed. Temperature now was 98° F. (36.7° C.), pulse 120, of poor volume, and respirations 24. An immediate blood transfusion was given and oxygen administered by B.L.B. mask. On Oct. 19 he had three profuse melana stools in quick succession, his general condition rapidly deteriorated, and he died later that evening.

Unfortunately a full necropsy was not possible, the stomach was removed. Examination revealed the presence of two distinct ulcers: the pre-pyloric ulcer which had perforated, with the perforation firmly closed, and a chronic ulcer, 3 cm. in its largest diameter, situated on the lesser curvature 7 cm. from the oesophageal opening, and covered by recent clot. The upper half of the stomach was filled with blood.

Masson and Simon (1927) reviewed the literature of multiple perforated gastric ulcers. They were able to find records of only 32 authentic cases, covering a period of 50 years. The large majority were of the "kissing" type—one on the anterior and the other on the posterior wall, opposite each other. No mention is made of a complicating haemorrhage from a second ulcer occurring simultaneously or following perforation of the first ulcer. Drury (1929) reported a case of multiple gastric ulcers in which two clean and perforated ulcers, 1 cm. in diameter, were found situated side by side on the greater curvature posteriorly. Gastro-jejunostomy had been performed on a previous occasion for a duodenal ulcer. Decoult and Driessens (1939) described three cases of double gastric ulcers with haematemesis. Anorosi (1931) reported a case of double gastric ulcer in which there was chronic double perforation into the pancreas and the anterior abdominal wall.

Reviews

CARBOHYDRATE METABOLISM

Carbohydrate Metabolism. Correlation of Physiological, Biochemical and Clinical Aspects. By Samuel Soskin, M.D., and Rachmiel Levine, M.D. (Pp. 315; illustrated. No price given.) Chicago: University of Chicago Press.

For some years now, in England at any rate, there has been a notable difference between the views on carbohydrate metabolism presented at different stages of a student's career. What is taught in the laboratory bears very little relation to what is taught in the wards. This might well result in a hopeless muddle in the student's mind; but perhaps, happily, he has developed an ingenious protective reaction. He forgets at each stage of his training everything learned in earlier stages, and is thus able to accept without blinking the view of the average general physician that diabetes mellitus is due to a deficiency of the islets of Langerhans.

In this volume Soskin and Levine present very fully and at the same time with brilliant clarity all that the intelligent clinician should know of carbohydrate metabolism and its relation not only to diabetes mellitus but to many other disorders of the endocrine and alimentary systems. Beginning with a discussion of the biochemistry and energetics of carbohydrate metabolism which even the reviewer, a clinician, found intelligible, the authors go on to discuss the nature of the breakdown of normal processes which occurs in diabetes and the role of the endocrine glands in the normal and abnormal processes. Very wisely the limelight is deflected from the pancreas on to the liver, the source of the blood sugar. The role of the pancreas, of the pituitary, and of the other endocrine glands is described very largely in relation to their effects on the carbohydrate function of this, the master organ.

At every stage the physiological and clinical aspects of the subject are clearly integrated. There is hardly a paragraph which the clinician can skip without loss, for even in the most theoretical chapters the clinical implications are clear. This is applied physiology at its best. It is to be hoped that copies of the book will soon be procurable without difficulty in this country.

A BOOK ON CANCER FOR LAYMEN

Science versus Cancer. By I. Berenblum, M.D., M.Sc. Sigma Introduction to Science 2. (Pp. 116; illustrated. 6s.) London: Sigma Books Ltd., 7, John Street, W.C.1.

This book is the second in a series of "Introductions to Science" which are intended, as the publishers announce, to explain in simple language the theoretical and practical aspects of modern science, medicine, and technology in such a way that those without previous knowledge of the subject can readily understand its significance. Formidable difficulties confront the writer of a book about cancer within these terms of reference. The layman approaches cancer with an emotion which astronomy or electricity does not arouse. Dr. Berenblum is alive to the almost universal dread of the disease, and where the reader's personal attitude to cancer may be influenced he writes with evident care and a sense of responsibility; but in his enthusiasm he seems to underestimate the intrinsic difficulty of his subject-matter. The book is written avowedly for the layman and in the belief that the bare facts (as presented in the "health propaganda" type of literature) are uninspiring and on the whole ineffective, while an account in non-technical language of the intricate and ingenious devices which the scientist uses in surmounting obstacles to reach his goal can be fascinating and inspiring to the layman as well as to the scientist. The layman, however, may be little wiser at the end unless he starts with a substantial knowledge of biology and a sympathy with the workings of the scientific mind. It is true that biological structures and processes are described for him in non-technical terms, but the simple, brief descriptions of cell, nucleus, mitosis, metastasis, and the like, while clear to those who already know, seem unlikely to dispel ignorance. The omission of technical terms by itself does not smooth difficulties or unravel complexities, and though the individual words be commonplace their association in the phraseology of the ward or laboratory is strange to the layman.

In sum, the reviewer does not think that Dr. Berenblum has made cancer or cancer research intelligible to the layman without knowledge of biology, and questions, moreover, whether anyone else could do so. With that reservation the book can be commended. It contains a wealth of information on various aspects of cancer, and within its limits it is up to date and reliable. Chapters are devoted to the nature of the disease and its frequency (there is a good discussion of the alleged rising incidence), the influence of heredity and of environment, diagnosis, and treatment. The chapter on diagnosis ends lamely, as it must when addressed to laymen, and it is of dubious value, while the remark that "the general position with regard to treatment leaves room for improvement" is surely a sizable understatement. The last portion of the book, about one-third of the whole, is devoted to experimental cancer research, where the author is on his own ground, and gives a good summary of current knowledge and ideas.

The medical practitioner can safely recommend this book to patients who possess an appropriate scientific background, and if he reads it himself he will probably find among much that is familiar a good deal that is new, and in particular he will find the answers to many awkward questions which patients ask.

PULMONARY OEDEMA

Pulmonary Edema and Inflammation. An Analysis of Processes Involved in the Formation and Removal of Pulmonary Transudates and Exudates. By Cecil K. Drinker, M.D., D.Sc. (Pp. 106; illustrations. \$2.50 or 14s.) Massachusetts: Harvard University Press; London: Oxford University Press. 1945.

Though the title of this book may seem recondite, it is addressed, like the lectures on which it is based, to an ordinary medical audience, and it is of great general interest. We must not think of oedema of the lungs and the pleural sacs only in relation to heart disease and hypoproteinaemia. The problems raised by Dr. Drinker cover a much wider field. They bear on the aetiology and treatment of pneumonia, the disposal of dusts from the lungs, the hazards of toxic gases, and the design of oxygen masks and breathing machines. Research in this field has been accelerated by two technical advances—the development of a technique for cannulating the lymph from the lungs and the discovery of a drug which has the specific action of increasing the permeability of the capillaries in the lung—and Dr. Drinker's experiments along these lines form the hard core of the book. One of his main conclusions is the extreme importance of anoxia in the development of pulmonary oedema, and the extent to which anoxia begets anoxia. No clinician will read this book without a better understanding of the local as well as the general significance of a normal alveolar oxygen supply. Dr. Drinker shows that oxygen is still given inefficiently and too late, and what is required from the physician is a sagacious alertness to the early use of oxygen. As a result of wartime developments in aviation medicine Dr. Drinker foresees transparent masks and hoods which will enable the physician to give any concentration of oxygen he wishes, while the patient will be able to converse with his attendants by radio equipment. Equally interesting is the suggestion that the Thunberg barospirator might be used for the treatment of respiratory infections, for this apparatus substitutes pressure changes for volume changes and allows the blood to be completely aerated with an immobile chest.

Dr. Drinker's monograph is clearly written, well illustrated, cheaply priced, and we can cordially recommend it to our readers. They will undoubtedly see their next dyspnoeic patient as it were through the transparent screen represented by the 40 sq. metres of the capillary field of the lungs, and they will reason and act accordingly.

TECHNIQUE OF ABDOMINAL OPERATIONS

The Surgical Technic of Abdominal Operations. By Julius L. Spivack, M.D., LL.D. Fourth edition, revised. (Pp. 710; 682 illustrations on 362 figures. \$10.00.) Springfield, Ill.: Charles C. Thomas. 1946.

It has been said with some truth that the only realm left to the general surgeon of the next generation will be abdominal surgery; even now some parts of this are becoming the territory of the specialist, as witness gynaecology and genito-urinary surgery. Perhaps that is the reason why in the fourth edition of *The Surgical Technic of Abdominal Operations* by Julius Spivack, of Chicago, one finds no reference to genito-urinary operations, though, as is the usual practice in some parts of

the United States, gynaecology is included, albeit very briefly compared with the general prolixity of the book.

In his preface the author points out that whereas a great number of books on surgery deal with "what to do" very little emphasis is placed on "how to do." This may be a doubtful criticism of the ordinary general textbook for students, but could certainly not be applied to the many excellent treatises on operative surgery, including abdominal operative surgery which are available to-day. The author, however, fulfils his promise of telling the reader how to do things; we feel that he has been even too detailed in many instances and is inclined to give the details of too many operations for any one condition. Thus nearly 40 pages are devoted to a description of almost as many different techniques for gastrotomy. Nevertheless we like the idea of giving a short historical summary of the evolution of an operation at the beginning of each chapter, as thereby the student may learn in a vivid manner how important steps in technique were devised to meet certain difficulties or hazards which arose in earlier cases. This is true education in the principles of surgery, and we believe it will be valued by the student. For the more experienced an excellent bibliography at the end of each chapter will enable them to refer to the original articles if they require further data.

There is certainly a plethora of instruction to be found here, our fear is that the ordinary medical student will be bewildered by it and may fail to see the wood for the trees. The illustrations deserve special praise—they are exceptionally clear and to the point; but here again one cannot help speculate whether surgical illustrations may not be too clear, for, we all know, there is perhaps no subject in which there is greater difference between the textbook illustrations and actual practice of surgery as seen in the operating theatre. The student therefore may be misled into a deceptive idea of ease and simplicity. The book is very well produced in a style characteristic of Charles C. Thomas of Springfield.

Notes on Books

Essentials of Clinical Allergy, by Dr. SAMUEL J. TAUB, is published in Baltimore by the Williams and Wilkins Company (London: Baillière, Tindall and Cox; 16s. 6d.). Books on allergy fall from the American printing presses as thick as leaves. Vallombrosa, and this latest one is of the usual pattern. The author is a professor of medicine, and the book is based on a large experience both of teaching and of allergy. The first chapters deal with the basic facts of immuno-chemistry and sensitization, and a interesting in reflecting the modern emphasis on the physical structure and configuration of the proteins. Nevertheless, we would doubt anyone after reading these sections to explain the mechanism of desensitization by the "rush" method of a patient with pernicious anaemia who has become sensitive to liver extract. There follow sections on hay-fever, asthma, and many other types of allergy. The presentation is well balanced, though perhaps less than justice is done to the important topic of drug allergy. It is also not worthy that in a book coming from the country of Alexander and the Society for Research in Psychosomatic Problems there is no discussion of the mental factors in allergy. Evidently New York is not America. Nevertheless this is an admirable book, and anyone who reads it well will have a good working knowledge of clinical allergy. There are accounts of the preparation of material for skin testing, case sheets for medical histories in asthma and allergy, diets and recipes for elimination diets, and so on. Finally the book is written in a lucid style, illustrated with attractive pictures of plants and poisons, and well produced.

Mr. W. H. MAXWELL, A.M.I.C.E., has written *Current Water Works Practice*—a practical treatise on the provision of water supply for urban and rural communities (B. T. Baisford, Ltd.; 18s.). Most of the contents are of technical concern to waterworks engineers and managers, and there is a long chapter of interest to public health officials on current methods of water purification. The volume is well printed and well illustrated. Mr. Maxwell writes with authority and has kept in view the latest aspects of present-day practice. There is an urgent need for an adequate and wholesome water supply for every dwelling throughout the country.

The return to normal conditions is reflected in the restoration of the former title of the *Fire Protection Year Book* (Lomax, Ebsknecht and Co., Ltd., Aldwych House, W.C.2; 7s. 6d. post free). This new edition has been thoroughly revised and brought up to date, much information has been added, and some sections which dealt with air-raid precautions have been cut out.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY NOVEMBER 9 1946

THE END OF THE BILL

The Government has accepted a number of amendments that came out of the Debate on the Third Reading in the House of Lords—that the gifts made to voluntary hospitals between the passing of the Act and the appointed day should be used by hospital management committees according to the wish of the donor; that the objects of all transferred endowments should so far as practicable be secured; that hospital management committees should be able to sue and be sued and control and manage hospitals on behalf of the Regional Board; that the associations of denominational hospitals should be preserved; that a practitioner should have proper representation if called before the Tribunal, that he could call witnesses, and that if he wished he could have the hearing in public.

The Lord Chancellor accepted an amendment by Lord Llewellyn to insert the words "whether in an honorary or paid capacity" after the word "serving" in Sub-section 2 of Clause 5: "The Minister may allow any medical practitioner serving [*whether in an honorary or paid capacity*] on the staff of a hospital . . . to make arrangements for the treatment of his private patients either at that hospital or at any other such hospital . . ." The interpretation of this amendment will be watched with interest.

In some instances where the Government could not accept an amendment, assurances were given by the Lord Chancellor; for example, that a medical practitioner should have six months' notice of the conditions of the National Health Service before having to decide whether or not he should enter it. The Government was defeated in the Lords by 35 votes to 15 on the amendment by Lord Balfour of Burleigh that the L.C.C. should have power to delegate maternity and child welfare and ancillary services to the City and Metropolitan Boroughs. It was defeated, too, on Lord Llewellyn's amendment that hospital management committees might sue or be sued and have their own right to make contracts for the daily services of the hospital—an amendment finally accepted by the Government. The most important amendment on which the Government was defeated in the Lords—by 53 votes to 37—was proposed by Lord Llewellyn, as follows:

"The remuneration to medical practitioners undertaking to provide general medical services in pursuance of the provisions of this Act shall be fixed by the capitation method except in any cases where the Minister on the recommendation of the Medical Practices Committee considers that exceptional circumstances necessitate remuneration on a different basis."

In the debate on this, Lord Moran expressed the misgivings of many doctors who were anxious about the impact of the Bill on the state of general practice in this country. One misgiving was the effect of the Bill when it became law on attracting suitable men into the medical

profession. The proposal to pay a basic salary required more justification than had been given. Lord Horder, supporting Lord Moran's view, pointed out that the Government's proposal would fix a ceiling above which no doctor could rise by his own efforts. Doctors had it firmly in their minds that the basic salary was the method by which the Government could attack the independence of the practitioner. In spite of Lord Addison's explanations of the reasons for introducing basic salary into the remuneration of doctors in the National Health Service, the real reason did not emerge until the Lord Chancellor on Thursday last week let the cat out of the bag—certification. "No one," he observed, "could have been, as I have been, Minister of National Insurance, without realizing that the success or failure of all our schemes depends in a very large measure on our getting satisfactory certification," and he went on to say: "If we are going to have lax—still more dishonest—certification, then all our schemes are going to break down on that rock." The Lord Chancellor, nevertheless, admitted that he had come across only some cases of lax certification where there were two competing doctors in a district, and remarked: "If you had abolished this per capita payment altogether and made it a straight out-and-out salary, of course, that temptation would have gone." In the Commons' debate on Monday, Mr. Aneurin Bevan's motion to disagree with the Lords' amendment on payment was carried by 303 votes to 128. Mr. Bevan defended the basic salary because it gave security to young doctors and to some extent would reduce the competition for patients. A basic element, he said, made it easier to give extra pay for special attainments. The Government's intention was that the main source of the doctor's remuneration should be by capitation. It would be difficult to carry out the recommendations of the Spens Report if the basic element were too high.

So the future remuneration of general practitioners in the National Health Service will contain a basic salary largely because of the Government's apprehension about certification. The next step, no doubt, will be for the Minister to invite representatives of the profession to discuss with him regulations and orders to be made under the authority of the Act. The plebiscite will decide what answer is to be given to the invitation.

THE DEPRIVED CHILDREN

Not often in these days does a Command Paper stir a rather tired and much castigated public conscience, but the report of the Care of Children Committee,¹ which was set up by the Government in the early part of last year to inquire into the methods of providing for children who had been deprived of normal home life, has caused uncomfortable reactions which may pave the way to early reform. The British are a children-loving people, whose indignation is fiercely aroused by any case of cruelty. What this report reveals is not active and intentional cruelty but indifference, lack of imagination, meanness of provision, absence of personal interest in and affection for these waifs and strays

¹ *Report of the Care of Children Committee*. Cmd. 6922. London: H.M. Stationery Office. 3s. net.

who have been cast upon a forbidding world. Numerically the problem is not a small one. It concerns 125,000 children. The largest group, some 57,600, consists of those maintained by public authorities under the Poor Law; they are housed mostly in public assistance institutions; some of them are in voluntary homes or are boarded out. The second largest group is of 23,400 children who, by order of a court, have been found to be delinquent or in need of care and protection; these are in approved schools or remand homes. Another 14,500 are physically or mentally handicapped, but not ineducable, and are in special schools; 7,500 more are mentally disordered or defective and cannot be educated, and are in mental deficiency colonies. Then there are a further 5,200, the floism and jetsam of wartime evacuation, who remain billeted in hostels or nurseries because there is no home to which they can return; there are 3,600 war orphans in foster homes, and 2,400 children awaiting adoption. In addition there are 10,000 children "maintained for reward."

The problem of these wards of the State is no less acute because it is largely tucked away out of sight. These children do not cross the common path. The ordinary citizen, if he thinks about them, supposes that Barnardo's or somebody will see to it. It was the same when the new Poor Law came in in 1834. It brought about such a tidying up of the streets, such a disappearance of vagrancy and destitution, that humanitarians like Harriet Martineau and enlightened politicians like Lord Brougham acclaimed it as a great reform; yet within five years Dickens produced his *Oliver Twist* just to show what it was like to be a pauper child. Another genius might base an awakening novel on some passages in this report which make one wonder whether we have advanced very much in a hundred years from Dickensian grotesquerie and squalor. Mr. Bumble has changed his coat but not always his heart, and the ghost of Mrs. Corney still flits about some institutions which are the same gaunt-looking buildings they always were, with dark staircases and corridors, high windows and bare boards, with the traditional chocolate-and-tuff paint and the eternal smell of mass cooking and soft soap. The children, of course, are not like the angelic and sensitive Oliver, who probably never existed in real life. These children are not usually pleasant, appealing little persons: they are often very difficult. Had *Oliver Twist* been pictured as a nail-biting, bed-wetting, destructive, saucy little varmint no Victorian would have shed a tear. But the children are the creation of their surroundings.

"One nursery which was structurally linked to the public assistance institution had sunk to the lowest level of child care which has come under our notice. There were 32 children on the register, eight of whom were sick children. . . . They were in charge of assistant nurses who were at the same time nursing the sick adults in the main ward, in which were aged and chronic sick (one patient had advanced cancer of the face), a mentally defective child, and a child with chicken-pox. In the children's ward was an eight-year-old mentally defective girl, who sat most of the day on a chair commode, because, the nurses said, 'she was happy that way.' . . . There were two babies with rickets, clothed in cotton frocks, cotton vests, and dilapidated napkins, no more than discoloured cotton rags. The smell in this room was dreadful. A premature baby lay in an opposite ward alone. The ward was very large and cold."

The report mentions one public assistance institution which twelve infants were cared for in one room where there was a mongol idiot; a boy of 10 and a girl of sleeping in the same room as a three-year-old hydrocephalic of very unsightly type; healthy children and children suffering from skin diseases of a contagious nature herded together; a public assistance home with a capacity for 45 overcrowded with 75 children. Many more examples could be quoted. On the other side there were places where the relationships and surroundings very nearly approached normal home conditions, and where matrons showed much kindness and understanding; but the Committee gives its general judgment: "We formed the conclusion that in the majority of public assistance institutions the general care of children was of a poor standard. We have no alternative but to paint this very gloomy picture."

A lack of adequate accommodation for mentally defective children is noted. Such children, it is said, are constantly found in Poor Law institutions for adults, remand homes, and, though not physically ill, in the wards of general hospitals. The Committee considers that an immediate census should be taken of ineducable children now in public institutions and children's homes and that the earliest possible steps be taken to provide for them in properly staffed homes and colonies. One phase of this problem concerns epileptic children, especially those who are both epileptic and delinquent or of low intelligence and are markedly unstable. There are not many of these cases but the problem seems to be out of all proportion to the numbers. Provision for this class should be on a national or at least a regional, scale.

Another matter for concern is that a few children regarded by medical superintendents as suffering from mental illness or severe defect are admitted to mental hospitals under the Lunacy and Mental Treatment Act. In these hospitals it has not been possible to make any special provision for them, and they are associated with adult mental patients in the wards and day rooms. It appears that some unstable boys and girls not suffering from any diagnosed mental illness are transferred under legal procedure from approved schools when they become uncontrollable. It is considered that alternative provision should be made for these children. As for the physically handicapped, in many hospitals insufficient attention is paid to education and educative recreation. Even where there are recognized hospital schools the children are left for many hours without occupation, and in some country hospitals no provision for education at all is made. One of the most serious difficulties encountered in dealing with the children in institutions and foster homes is enuresis, a reflection of the child's sense of insecurity. Incidentally the Committee comes down in favour of the abolition of corporal punishment in all institutions. Corporal punishment may be all very well for boys in a happy home with full confidence in life; it is disastrous for a child with an unhappy background, whose self-respect needs to be nourished and who needs to feel that he is regarded with some affection by those in charge of him.

The recommendations number over sixty. An outstanding proposal is that the administrative responsibility for the

re of children deprived of home life should be centralized in one Government department; at present it is spread over five departments. This was also the view of the recent conference of Labour Women, at Hastings, meeting on the day this report was issued. The single department could define requirements, maintain standards, advise and assist those taking immediate responsibility, and act as a clearing-house for progressive ideas. All services of local authorities should be subject to Exchequer grant, so relieving the difficulties arising from straitened financial resources in certain areas. Many recommendations are made for registration and inspection, also for changes in the law relating to adoption.

The Committee, of which Miss Myra Curtis was chairman, and which had among its 16 members two medical men, Mr. Somerville Hastings and Prof. J. C. Spence, carried out its work with great thoroughness. It examined 29 witnesses (including five from the British Medical Association, led by Dr. R. G. Gordon), considered 114 memoranda, and visited, individually or in small groups, 51 institutions. It is understood that the Home Secretary and the Ministers of Health and Education are giving immediate attention to what this critical report reveals and recommends, and that proposals may be laid before Parliament early in the session which is about to open. However crowded the legislative programme may be, this subject calls for high priority. This is demanded in order to deal effectively with what is nothing less than a scandal in some parts of our local administration, to relieve the wretched and hopeless lot of many of these children, and to preserve the next generation from being invaded by an army of the unfit, the witless, the maladjusted, the resentful, the depraved, the criminal, which such surroundings inevitably nurture.

WHOOPING-COUGH VACCINE TRIALS

In conjunction with the Medical Officers of Health of Manchester, Tottenham, and Wembley the Medical Research Council is initiating field trials to assess the protective value of pertussis vaccines. In these three areas parents of children aged 6-12 months have been invited to co-operate by enrolling their children for inoculation within the next few months. The volunteer children are to be divided into two groups, one group receiving pertussis vaccine and the other—the control—anticatarrhal vaccine. Details of the investigation are so arranged that no one engaged in the day-to-day work of inoculation and subsequent follow-up will know which vaccine any particular child has received. The children are to be visited at monthly intervals by specially appointed health visitors, who will take specimens for bacteriological examination from any child with a suspicious cough and arrange for specially appointed medical officers to visit the child and make a clinical diagnosis. The results will be assessed at the end of two years.

In the propaganda to parents—mainly by pamphlets and personal visits by health visitors—all the details are fully explained. The enrolment of children has so far been encouraging. All general practitioners in the areas concerned have had a letter informing them of the investigation and have been asked to co-operate by reporting suspicious coughs in children included in the trial. The

general practitioner will immediately be informed when whooping-cough is diagnosed by the special investigators.

At present American vaccines as prepared for Prof. Sauer, Evanston, and Dr. Pearl Kendrick, Grand Rapids, both of whom have claimed considerable success with prophylactic vaccination, are to be used. Previous results obtained in controlled trials with a British vaccine had proved disappointing; that is why American vaccines are now being tried. If they prove satisfactory further trials will be made with new British vaccines.

UTERINE CANCER AFTER IRRADIATION

From time to time it has been noted that women of premenopausal age treated with radium or x rays for functional uterine haemorrhage sometimes develop carcinoma of the uterus at a later date. Some authorities have regarded this as a chance occurrence; others have suggested that the local effect of the radium favoured the subsequent development of malignancy. In many cases, however, there is little doubt that the patient already had carcinoma at the time of the radiotherapy, and even though curettage was carried out the correct diagnosis was not made. The incidence of malignant disease of the uterus after radiotherapy for innocent conditions has been variously assessed as between 0.3 and 1.46%, but the material and methods used by several investigators have differed so much that it has been difficult to reach any definite conclusion.

J. A. Corscaden, J. W. Fertig, and S. B. Gusberg¹ now report on a follow-up of 958 women subjected to an artificial menopause. The average follow-up period was 6.7 years. Thirty-six patients developed cancer, and in fifteen of these it was situated in the uterus. Presence of the growth at the time of the original treatment was excluded by the long interval before the return of symptoms (four years or more in all cases except one). From the cancer mortality rates for each age group of the female population of the United States as a whole it is calculated that the expected incidence of malignant disease in this group was 17.4, the growth being situated in the uterus in 4.4 women. Although there was no significant difference in the occurrence of extrauterine cancer there were 3.4 times as many cases of uterine cancer as might have been expected. It is further calculated that of all women aged 30-55 treated for uterine haemorrhage by induction of the menopause with radium or x rays 9.6% will suffer from uterine cancer before they reach the age of 80 years.

The carcinoma was situated in the body of the uterus in nine of the fifteen cases, and in the cervix in six. The indication for radiotherapy was always excessive bleeding, and in the majority the original curettage had revealed hyperplasia of the endometrium. The idea that it is the action of the radium which predisposes the woman to carcinoma is dismissed, and it is concluded that it is conditions demanding such treatment—i.e., haemorrhage before the menopause and endometrial hyperplasia—which are the significant factors.

The difficulty of the subject is emphasized by the appearance in the same journal of a report by G. T. R. Fahlund and A. C. Broders² on a study of 236 uteri removed after the menopause, carcinoma being present in 86, and 50 being without any pathological change. They conclude that endometrial hyperplasia does not predispose to malignant disease or play any part in its aetiology. On the

¹ *Amer. J. Obstet. Gynec.*, 1946, 51, 1.

² *Ibid.*, 1946, 51, 22.

contrary, they found that it is the uterus with an atrophic endometrium that is most likely to develop carcinoma. This is directly opposed to the view which has been widely but not universally held in the last two decades, and also to the suggestions put forward by Corscaden and others to account for their findings. Indeed it offers an alternative explanation of the latter. Whatever be the explanation, however, if the analysis of the cases studied by Corscaden *et al.* is not upset on statistical grounds and if further clinical evidence is forthcoming to support their findings as to the incidence of malignant disease, the desirability of treating "menopausal bleeding" by hysterectomy rather than radium must be considered from the standpoint of the prevention of uterine carcinoma later in life.

TUBERCULOSIS: AN EMPIRE RESPONSIBILITY

Sixty million people live in the British Colonies—that is, apart from the great Dominions—and these colonial fellow-subjects of the Crown are obtaining more self-government each year. In the exhaustive plans now being made for their welfare it is curious that tuberculosis seems to be overlooked. Yet it is as much a "tropical" disease as malaria or sleeping-sickness. As Africa and Asia become industrialized, as communications grow and cities swell there is every reason to fear that endemic tuberculosis may be as serious in the less-developed areas as it has become during the past century in Great Britain. A survey on *Empire and Colonial Tuberculosis* by Prof. Lyle Cummins¹ is therefore of timely interest. It begins with a dictum of Robert Koch's asserting that the number of victims claimed by such dreaded diseases as bubonic plague and cholera must rank far behind tuberculosis. The same may be said of the more chronic diseases of the Tropics, which cause more horror among the public and attract more attention among doctors. The booklet gives an outline of native infection and immunity by one who has studied the problem for more than thirty years, ever since, as a young medical officer in the Sudan, he wrote his early paper on disease in that sub-equatorial region. The pioneer survey of Lyle Cummins has been followed by others; Wilcocks, Matthews, and Bardswell have each examined tuberculosis in a different part of the Empire, and a survey of the West Indies by Santon Gilmour has also been published by the National Association for the Prevention of Tuberculosis.²

Though present knowledge does not enable Lyle Cummins to be dogmatic, he thinks that the difference between the European and non-European natives in their reaction to tuberculosis is the difference in the speed at which immunity takes place. In civilized man relative immunity is acquired with fair rapidity. In the primitive it grows slowly, and in the meantime serious and fatal disease may have taken place. The N.A.P.T. *Handbook of Tuberculosis Activities* (1946) contains for the first time an Empire and Colonial Supplement, and it is depressing to look through the references to colonial medical services and find the small attention paid to the disease. In Nigeria, for instance, with its population of twenty millions, there are only fourteen beds specifically assigned for the treatment of tuberculosis. All recent evidence from Colonial Africa and other parts of the Empire suggests that native peoples are beginning to pass through an intensive phase of contact with the tubercle bacillus, combined with those changes from their primitive mode of life which, when applied

together, cause a high death rate from tuberculosis. The Bantu and the Hottentot and the many other races and peoples under the tropical sun are now to experience a transition from simple agriculture to mining and factory life. Can our knowledge of European deterioration during the industrial revolution be used to help them?

The N.A.P.T. has promoted surveys in Cyprus, Burma and the West Indies and now has begun a further survey in the Gold Coast. The problem of colonial tuberculosis it is being realized, is far more urgent than anything in this country but has so far not been matched by any real expansion of medical services. Prof. Lyle Cummins' booklet, which is part of the National Association's programme of colonial research and education in tuberculosis ought to receive attention in places where plans are made for the conquest of social disease.

INTERTRIGINOUS DERMATITIS OF THE FEET

Skin affections about the toes, especially the intertriginous affections, cause much difficulty in diagnosis and treatment; they are often loosely diagnosed as dermatophytosis though fungous infection probably accounts for no more than 30% of such cases. Bacterial infection, trauma, and sweating may produce a very similar clinical picture. This group of diseases constitutes a hazard in some industries and during the recent war it became a major cause of disability in the Armed Forces, more particularly in tropical and subtropical theatres. There is no single treatment of outstanding merit, and recurrence after apparent cure is the rule.

All these points are stressed by Weidman and Glass, who during the winter of 1942-3 conducted an experiment upon 117 men in a penitentiary in America. They chose patients suffering from intertriginous dermatitis of the feet "conceivably due to bacteria or to fungi," with the intention of finding a "blanket form of treatment" not determined by laboratory tests and not requiring close medical supervision, the purpose of which was prophylaxis—keeping "the feet of fighting men in good condition." Though the object was to advise upon treatment suitable for use "in the field" away from laboratory facilities, they did in fact take a single culture in each case and secured the high figures of 37.9% positive results. However, this was secondary to the main purpose of the investigation.

Six medicaments were investigated, including benzoic and salicylic acid ointment, but two proved far superior to the remainder. Metacresylacetate ("Cresatin-Sulzberger"), regarded by the authors as the more valuable, and 5% boric acid powder in talcum each gave apparent cure in 16% of cases and improvement (including the cures) in 75%. No reference is made to recurrences. Benzoic (12%) and salicylic acid (3%) ointment effected improvement in 75% but apparent cure in only 5% of cases. The results leave much to be desired and indicate the need for serious research.

Certain other facts of interest emerge from this preliminary report, as that the incidence of infection did not seem to be influenced by wooden, cement, or stone floors. There was no obvious correlation between the clinical findings and the type of fungus involved and no difference in the response of the different fungous infections to the various medicaments. *Trichophyton purpureum* was the fungus commonly found in the white cases and *Trichophyton interdigitale* in the negro, and there appeared to be a striking decrease in incidence of these disorders after fifty years of age.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

An annual report of more than usual interest is that of the London School of Hygiene and Tropical Medicine (incorporating the Ross Institute) for the year 1944-5. The year is that during which the war, with its many changes in peacetime conditions, ended and a return to more normal working began. The total number of Service medical officers who were given special instruction in tropical medicine and parasitology during the war was 2,259, but during 1944-5 the requests of the Services became less and only four courses were provided for a total of 221 men and women. The total number of students provided with instruction was 436. The intensive courses are now discontinued, and courses for the D.P.H. and for the D.T.M.&H. are already in progress:

An outstanding event has been the gift of over £20,000 from the Rockefeller Foundation to the public health department for the training of picked men who may afterwards reinforce the teaching staff of the School and fill important vacancies in the public health services. The work of the School during the year was very varied and largely determined by urgent need for researches and advice for war purposes. It is a tribute to the high repute of the School that during the period under notice the Foreign Office, the Colonial Office, the Ministry of Supply, the British Council, and important industrial bodies sought the expert assistance of the staff for inquiries and investigations at home and over-seas. Prof. H. Raistrick, who in July, 1944, was appointed honorary scientific adviser on penicillin to the Ministry of Supply, paid two visits to the United States and made useful contacts in connexion with the production of penicillin. Prof. P. A. Buxton visited the Gold Coast during the early part of the year in connexion with the use of D.D.T. and later went to East Africa at the request of the Colonial Office to report on research on tsetse-fly and trypanosomiasis. Dr. George Macdonald, who took up his new duties as Director of the Ross Institute on Jan. 1, 1945, visited and reported upon health conditions in Iran for the Anglo-Iranian Oil Company. Other investigations and researches have been carried out in the departments of parasitology, entomology, biochemistry, epidemiology and vital statistics, applied physiology, and public health. An account is also given of the work of the large and very useful library of the School, of the Agricultural Research Council unit of insect physiology, of the affiliated Institute of Agricultural Parasitology under Prof. R. T. Leiper at St. Albans, and of the Ross Institute. A plea is made for repair of the east wing of the building in Bloomsbury, damage to which has greatly curtailed much-needed accommodation.

THE "SERVANT PROBLEM" IN HOSPITALS

"Hospital domestic work is at present an unpopular occupation, particularly among women used to factory conditions." So stated the Factory and Welfare Advisory Board in requesting King Edward's Hospital Fund for London to examine the question of the employment of domestic staff in hospitals. The truth of the observation was immediately borne out by the Fund's own inquiries. Of sixty voluntary hospitals of all sizes in its area all but five reported a serious shortage of domestic staff. The Fund set up a small committee under the chairmanship of Mr. Malcolm McCorquodale, Parliamentary Under-Secretary for Labour in the last Government, to formulate recommendations; and the recommendations¹ should

go some way to ease the problem as far as it can be eased without touching on payment, which was outside the committee's province. All it states on this point is that hospitals should not feel themselves bound by the minimum rates of the Joint National Council if, in order to compete with other employment in the neighbourhood, it seems necessary to offer something above the minimum. Nearly all the hospitals from which evidence was sought referred to wages as the main factor in the situation.

One of the principal recommendations is that there should be appointed to all hospitals of sufficient size a full-time domestic supervisor and welfare officer of the right personality, who, under the matron, would have charge of recruitment, interviewing, engagement, placement, training, payment, and welfare. Then there is real need in hospitals for guidance in the use of labour-saving appliances and methods of working. The committee had to abandon its intention to indicate a standard complement of domestic staff in a hospital. With the nursing staff a ratio of nurses to patients offers a reasonable basis, but with the domestic staff, who are responsible for the care of premises as well as the service of individuals, so many variants arise that it would be unsound to lay down a ratio of staff or of man-hours to beds. But it is mentioned that one of the very few hospitals which felt that its difficulties concerning domestic staff were below the average was trying an over-all ratio of one member of domestic staff to five beds.

On the vexed question of nurses undertaking domestic duties the committee feels that some training in domestic work is a necessary part of the nursing course if the nurse is to understand the proper care of the patient's environment; but it is a different matter to depend permanently on the nurses in training for a substantial share of the domestic labour of the hospital. Teaching and practice in housecraft should be a recognized part of the nurse's training, but the domestic requirements of the wards should not be dependent on the student nurses to such an extent as to absorb a substantial share of their time and energies.

Another recommendation is that hospitals should consider the greatly increased employment of male domestic orderlies. "We see no reason why, in men's wards at least, there should not be a male orderly for domestic duties." Various other recommendations are made about hours of duty, accommodation and amenities, health, pensions, and, finally, uniform. With the nurses wearing uniform there is not likely to be the same objection on the part of the domestic staff to a "badge of servitude" as might be found in ordinary domestic service, and at one hospital the green overalls and caps provided for the ward orderlies are very popular.

The National Health Service (Scotland) Bill "to provide for the establishment of a comprehensive health service for Scotland and for purposes connected therewith" was presented in the House of Commons on Oct. 31 by the Rt. Hon. J. Westwood, Secretary of State for Scotland. It was ordered to be printed, but will not be debated until the new session of Parliament which is due to begin on Nov. 12.

The next session of the General Medical Council will open on Tuesday, Nov. 26, at 2 o'clock, when the President, Sir Herbert Lightfoot Eason, will take the chair and deliver an address.

MORALE IN BATTLE

ADDRESS GIVEN TO THE ROYAL SOCIETY
OF MEDICINE

BY

FIELD-MARSHAL VISCOUNT MONTGOMERY

I have chosen for my talk the subject of morale in battle. High morale is a quality without which no war can be won; it is therefore a vital quality. And since it is a mental quality, because it is essentially the product of a mind and a conscience, it will be of peculiar interest to the medical profession.

We must first understand what we mean by "morale." This is wrapped up in the human factor, since the raw material with which we soldiers have to deal is "men."

The Human Factor

I would like to begin by giving you my general views about the nature of our Army. One great lesson stands out clearly in my mind from the late war, in which we went through some very bad times, but stood up undaunted, and then hit back. It is this. The true and ultimate strength of a nation lies in its people, in their capacity to work, in their virility. It lies, in fact, in the national character. It is this national character that produces the fighting-man—the soldier.

The soldier is not chiefly a military figure; he is primarily a social figure. He is influenced by his home, his upbringing, and his historical tradition. He is only a soldier because military training has imposed a certain fixed pattern of behaviour upon him. The soldier is, in fact, a citizen of the nation. The Army is woven into the social fabric of the nation and is an integral part of the community. No matter what may be instilled into him in the Army, the soldier will retain his individual character, which he derives from his environment. He will reflect, primarily, the national character of his country. The national character is therefore of immense importance. Anything that weakens the national character weakens the Army. An army is not, and never can be, merely a collection of individuals. It is a fighting weapon moulded by discipline and controlled by leaders. The aim of an army is to achieve success in battle against the enemies of the nation. All training must be directed towards this end, and it must never be forgotten even though the country is at peace. Training must from the earliest days concentrate on the selection of leaders and the infusion of discipline. It is by discipline that an army is welded into a fighting weapon; it is by leadership that it is led to victory. These are the fundamental factors which affect the morale of the soldier and lead to success in battle.

The Quality of Morale

In war the moral stature of some men increases, and their characters grow stronger and more closely knit in proportion to the discomforts and dangers they are called upon to face. Such men will occasionally perform in battle remarkable acts of selfless courage and daring, and will endure with extraordinary fortitude and patience the burdens thrust upon them. Other men, however, will under the stress of hardships or dangers surrender to fear or fatigue and will allow their characters to disintegrate. This disintegration will usually take the form of a loosening of the moral fibre, which results in timidity of action and slackness in appearance, while those who have gone to seed will be dirty and their appearance will be even more so. In these latter cases there has been a general loosening of the character due to a partial surrender to fear. The good soldier—the man with high morale—has not surrendered to fear and has maintained his personal standards; the bad soldier—the man with low morale—has become incapable of independent action and has to some extent shed a part of his human individuality.

Morale is a mental and moral quality. It is that which in battle keeps men up on humanity's level. But humanity's level is not enough, because the strongest human instinct is the instinct for survival. Morale is also that which develops man's latent heroism so that he will overcome his desire to take the easy way out and surrender to fear. The quality which maintains human dignity in battle and at the same time develops man's heroism is high morale. It is necessary now to make

clear what high morale is not. It is not contentment or satisfaction bred from ease or comfort of living. Both of these contain a hint of complacency; an acceptance of luxury as an end in itself. High morale is far more than any of these for it implies essentially the ability to triumph over discomfort and dangers and carry on with the job.

Nor is high morale achieved through fitness or healthiness alone. It is important not to confuse the idea of physical happiness with morale. The happy faces of men after a good game of football are not necessarily the faces of men with good morale. Morale is a mental rather than a physical quality, a determination to overcome obstacles, an instinct driving a man forward against his own desires. High morale is not happiness. Happiness may be a contributory factor in the maintenance of morale over a long period, but it is no more than that. High morale is not toughness. Some very tough men in war have turned out to be very disappointing in action. Toughness is a physical and not a mental asset. Tough men will occasionally perform an isolated act of bravery. Morale, however, is not a quality which produces a momentary act. It influences behaviour at all times.

In brief, high morale is a quality which is good in itself and is latent in all men. It maintains human dignity. It enables fear and fatigue to be overcome. It is involved with the idea of conscience, but it should not be confused with fitness or happiness or toughness.

Basic Factors of Morale

We must now consider what factors constitute the morale of the soldier in the heat of battle. Certain factors may be described as essential conditions without which high morale cannot exist. These four basic factors are: (1) leadership (2) discipline, (3) comradeship, (4) self-respect. A fifth factor, devotion to a cause, must exist but need not necessarily influence all the soldiers. Finally, there are numerous contributory factors which are of great importance but are not essential conditions.

Leadership

Morale is, in the first place, based on leadership. Good morale is impossible without good leaders. Human beings are fundamentally alike in that certain common characteristics apply to all men in varying degrees. In battle the most important of these characteristics is fear. All men are afraid: one time or another to a greater or lesser extent. In moments of fear they band together and look for guidance; they seek for a person to give decisions; they look for a leader.

In times of war the leader has opportunities denied to him in peace. The difficulties, dangers, and discomforts inseparable from the battle-field make men cry out for the leadership they can do without in peace. At such moments men are too weak to stand alone; they find the burdens too great to bear on their own selves unequal to the task. The leader himself accepts the burdens of others and by doing so earns their gratitude and the right to lead them. The men recognize in their leader some quality which they themselves do not possess; this quality is "decision." Fear makes men sluggish and indecisive, unable to decide or act for themselves. The leader's power over his men is based on his ability to cut through this "fear paralysis," and in so doing to enable others to escape from it. The rightness of the decision taken by the leader is irrelevant. What matters is that the decision should be taken and that the leader should shoulder the responsibility for the decision. The leader must convince his men of its rightness even though he himself may be uncertain of his own judgment. If the leader will decide, the men will follow and will fight. If there is indecision they will hesitate and will flee. In short "fight and survive," "fear and be slain"; the leader decides.

The leader's power of decision results from his ability to remain imperturbable in the crisis. His greatest asset is his ability to act normally in abnormal conditions, to continue to think rationally when his men have ceased to think, to be decisive in action when they are paralysed by fear. The object of training must be, first, to select those who possess within them the potentialities of leadership, and, secondly, to develop these potentialities. This is accomplished by giving the leader responsibility. A leader's character will develop in proportion to the responsibility with which he has been entrusted. His

osition as the man responsible for the lives and well-being of his men must be impressed upon him. In battle his preoccupation with his men's affairs will give him less time to sink of his own fears. The mere fact of responsibility will increase the leader's powers of decision and make him confident of his ability to handle any crisis. The two vital attributes of a leader are: (a) decision in action, and (b) calmness in crisis. Given these two attributes he will succeed; without them he will fail. Our great problem in peace is to select as leaders men whose brain will remain clear when intensely frightened; the yardstick of "fear" is absent.

Discipline

The object of discipline is the conquest of fear. There are two aspects of fear. Fear can suddenly attack a man through his imagination. A corpse in a ditch or a grave by the side of the road will remind him of the peril of his position. He will suddenly realize that he himself is liable to be killed. It is

function of discipline to fortify the mind so that it becomes reconciled to unpleasant sights and accepts them as normal everyday occurrences. Fear can also creep upon a man during periods of monotony in the line. At such a time he will have the opportunity to appreciate the dangers which beset his life. Fear acting through his thoughts can so reduce the man's hard core of courage that he will become nervous and fearful. Discipline strengthens the mind so that it becomes impervious to the corroding influence of fear. It teaches men to confine their thoughts within certain definite limits. It instills the habit of self-control.

The basis of fear is the awareness of danger. Man becomes aware of danger when he feels himself opposed to something more powerful than himself. It is important for a man to lose his individual feeling and to become an integral part of the battalion, division, and army to which he belongs. It is here that discipline shows its value, for it can help a man to lose his own identity and become a part of a larger and stronger unit. It is in this way that discipline will conquer fear. This corporate sense which discipline creates helps men to face the unknown.

The method by which the conquest of fear is achieved is the unifying of men into a group or unit under obedience to orders. Men require to be united if they are to give of their best. Discipline seeks to instill into all ranks a sense of unity by compelling them to obey orders as one man. This obedience to orders is the indispensable condition of good discipline. Men learn to gain confidence and encouragement from doing the same thing as their fellows; they derive strength and satisfaction from their company; their own identities become merged into the larger and stronger identity of their unit. Men must learn to obey orders when all their instincts cry out for them not to be obeyed. They must learn to obey orders in times of stress so that they will do so in times of danger. They must learn to carry out their tasks under any conditions and despite all difficulties. In this way the mass of loose individuals, with their fears and weaknesses, can be welded into a united whole, ready to act on the word of a leader.

Discipline implies a conception of duty. Nothing will be accomplished in the crisis by a man without a sense of duty. The sentry in an outpost holds his ground in the face of attack because he has a sense of duty to those behind him. This sense is instilled by discipline because it teaches men to obey orders as a matter of course, to know that it is wrong not to obey them, and right—that is, their duty—to do so. For the soldier this conception of duty does not embrace abstractions such as freedom or empire or democracy. In battle a soldier's sense of duty extends only to the friends who are around him. It is the job of the junior leader to encourage this sense of duty. In brief, discipline seeks to conquer fear by welding men into a cohesive whole, united by obedience to orders. It aims to create a body strong enough to carry each of its members through dangers and difficulties which they themselves would be unable to face alone. In this way it promotes comradeship, which is the third factor of morale.

Comradeship

Morale cannot be good unless men come to have affection for each other; a fellow-feeling must grow up which will result in a spirit of comradeship. An army is made up of human

beings, so that however much a leader may inspire his men, however perfect the discipline, the morale will be hard and unsympathetic if the warmth of comradeship is not added to it. War, though a hard business, is not necessarily a grim one. Men must laugh and joke together, must enjoy each other's company, and must get fun out of life even in times of danger. Comradeship is based on affection and trust, which between them produce an atmosphere of mutual good will and a feeling of interdependence. Men learn to have faith in each other and to depend on each other according to the abilities of each. Comradeship is a great antidote to fear because it gives a man friends. If he has friends he will derive strength from their presence and will be anxious not to let them down in battle. All men have within them a streak of generosity and unselfishness—a touch of nobility—and these qualities will be brought out in their attitude to their friends. Friendship causes men to give of their best.

In conclusion, comradeship is vital to high morale because it surrounds a man with an atmosphere of warmth and strength at the very moment when he is feeling cold and weak. It encourages his finest instincts, and the demands of friendship serve to strengthen him in battle. These demands are also a challenge to his self-respect—a quality which must now be considered.

Self-respect

No man can be said to possess high morale if the quality of self-respect is lacking. Soldiers must be encouraged to respect themselves at all times and under all conditions. Self-respect implies a determination to maintain personal standards of behaviour. A man who respects himself will allow neither himself to become slovenly nor his quarters dirty; even in action he will take care to see that his personal appearance suffers as little as possible. It is the job of the N.C.O. to maintain this aspect of discipline; it is the function of the officer to encourage and instil self-respect.

Efficiency is inseparable from self-respect. Men must take pride in their ability to carry out all jobs allotted to them. They must feel that they are good soldiers and are therefore of value to other people. Men can be persuaded of this fact by being trusted. A man who feels he is trusted will feel that he is efficient, and he will at once begin to respect himself. He will have confidence in his own ability to fight. Men who are trusted gain self-confidence. It is the job of the officer to convince his men that he trusts them. Self-respect is a quality which will develop inevitably if the three essential factors already considered are present. It is true to say that without self-respect good morale is impossible; it is equally true to say that if the standards of leadership, discipline, and comradeship are high, the quality of self-respect will also be high.

Devotion to a Cause

It is impossible to make devotion to a cause either a basic or a contributory factor to good morale. It must stand by itself between these two categories. I do not believe that soldiers are greatly influenced by "cause"; they do not advance over dangerous and fire-swept ground in the conscious pursuit of an ideal; they fight for reasons which have little obvious connexion with freedom or democracy. There are of course exceptions. But rhetorical statements which assert that the soldier

"... must know what he fights for
And love what he knows"

must not be allowed to confuse the issue. The fact is that the soldier, instead of baying a "fire in his belly," advances into battle with a cold feeling inside him. These statements must be qualified.

No nation could fight an unpopular war; the war must be accepted by the people, since a democracy cannot oppose the will of the majority of its citizens. The soldier, as a citizen, must therefore be convinced of the rightness of the cause. At least his reaction to the declaration of war must be one of acquiescence, even if this is only passive; he must not be hostile to it. The way to change this passive acceptance to active enthusiasm in battle has already been given in the four basic factors. Nevertheless, nothing which I have said must be interpreted as minimizing the influence of "cause" on those officers and men who are moved by it. For these few, "cause"

will be a sustaining and strengthening factor and may be of greater importance to them than any of the four factors.

Contributory Factors

There are certain contributory factors which powerfully assist morale but do not themselves constitute essential conditions for it. It is possible to have high morale without any of these contributory factors, but it is very difficult; it requires the highest standards of leadership and discipline and the strongest feelings of comradeship and self-respect. In the normal case one or more of these contributory factors must be present. There are many of them, and only a few are considered here.

Success.—High morale is possible in defeat but not during a long period of defeat. On such occasions confidence in the leaders will inevitably wane and the first basis will be undermined. Success will aid good morale by creating confidence in the leader and in the command.

Regimental Tradition.—The regimental spirit can be a powerful factor in making for good morale. The more a soldier feels himself to be identified with his regiment the higher will be his morale if the four essential conditions have been fulfilled. There is a difference between comradeship and regimental spirit. Comradeship is the spirit of fellow-feeling which grows up between a small group of men who live and work and fight together. Regimental spirit is the soldier's pride in the traditions of his regiment and his determination to be worthy of them himself. Nothing but good can result from this spirit, which should be constantly encouraged; it is not, however, a basic factor of morale, because in the crisis of battle the majority of the men will not derive encouragement from the glories of the past but will seek aid from their leaders and comrades of the present. In other words, most men do not fight well because their ancestors fought well at the Battle of Minden two centuries ago, but because their particular platoon or battalion has good leaders, is well disciplined, and has developed the feelings of comradeship and self-respect among all ranks on all levels. It is not devotion to some ancient regimental story which steels men in the crisis; it is devotion to the comrades who are with them and the leaders who are in front of them.

Personal Happiness.—A man should be happy in the sense that his personal life should be in order. Nothing weakens a man more than trouble at home; it encourages him to think of home, and all that it implies, when he should be occupied with the enemy. It turns his mind to peace and his desire to live at the moment when it is necessary for him to steel himself to face the possibility of death. He must never be allowed to forget that his job is to fight. His function is to kill the enemy, and in so doing he must expose himself to danger.

Administration

A man's ordinary day-to-day life must be well organized. Thus, hard conditions imposed on him in training to inculcate discipline do not rule out the desirability of good living-quarters; and in the line a soldier's morale will be much improved if the administrative arrangements are good and if he is assured of proper conditions, with a reasonable amount of leisure and comfort when he leaves the front. But here warning must be given. There is a danger to-day of "well-being" being considered as an end in itself and not as a means to an end, one of the means of maintaining morale. Welfare itself will not produce good morale because it is essentially a luxury and it has already been stated that morale cannot be good unless it contains a quality of hardness. Hardness and privation are the school of the good soldier; idleness and luxury are his enemies. Men will endure great hardships if they know why and are convinced of the necessity. "Blood, toil, tears, and sweat" is not for nothing one of the great rallying calls of the English race. Goering's cry, "Guns before butter," expressed the same truth. If men believe in the need, hardships are in themselves a stimulant to morale. But the opposite is also true. Let there be any suggestion that butter can come before guns and some men will at once choose the butter. If this happens there will be no morale in the sense of this definition.

Propaganda.—The uplifting effect of modern propaganda a soldier is perhaps a new development. A man's morale raised immensely by feeling that his efforts are appreciated and applauded, not only by his comrades and his officers but by the world at large. Remarkable results can be achieved by the use of modern publicity methods. These results will be achieved only if the fighting soldier is differentiated from the soldier who serves behind the fighting line. The latter often works at dull, monotonous jobs and lacks the stimulus of battle conditions; it is good for his morale that his work should be publicized in the press. But it is no good writing of the Bren gunner and the G.H.Q. clerk in the same terms. The sharp distinction between those who risk their lives in actual battle with the enemy and those who do not must not be blurred. A fighting soldier thus glorified will soon become convinced of his own importance. This artificially stimulated feeling of self-importance is a quality lower and less lasting than that of self-respect, but it is none the less of momentary value.

Conclusion

In brief, high morale has been defined as the quality which makes men endure and show courage in times of fatigue and danger. The cultivation of morale depends upon the training of leaders, the inculcation of discipline, the encouragement of comradeship, and the infusing of self-respect. The leaders must have a belief in their cause, and they must pay attention to numerous contributory factors of considerable but secondary importance.

We live to-day in a scientific age. But we soldiers have to remember that the raw material with which we have to deal is "men." Man is still the first weapon of war. His training the most important consideration in the fashioning of a fighting army. All modern science is directed towards his assistance but on his efforts depends the outcome of the battle. The morale of the soldier is the most important single factor in war.

CENTENARY OF ANAESTHESIA CELEBRATION DINNER

As part of the centenary celebrations of the first administration of ether the Association of Anaesthetists of Great Britain and Ireland held a dinner in the Great Hall of Lincoln's Inn, Oct. 31 under the Presidency of Dr. A. D. Marston. Proposed to the toast of the association Sir Alfred Webb-Johnson said that the centenary marked the beginning of the most brilliant phase in the history of British medicine. He praised the anaesthetists for having raised the standard of their specialty by insisting on a diploma and recognition of the status of anaesthetists. "You are," Sir Alfred said, "practising physicians. You administer drugs of very high potency." In reply, the President thanked the College of Surgeons for the facilities granted to his association. As an example of the increased scope of the anaesthetists' work he observed that in Birmingham anaesthetists were responsible for anti-shock and resuscitation work. The position of the specialist anaesthetist was becoming recognized, and "we now have a Group within the B.M.A." To the toast of the guests was proposed by Dr. John Gillies, and in reply Dr. Charles Hill referred to the two-way links of the Association of Anaesthetists—in the academic sphere with the Royal Colleges and in the medico-political sphere with the B.M.A. The B.M.A. would see that in any future National Health Service the anaesthetists would be assured of the proper role and status. As a profession, he said, we seek to quarrel with established authority, but we have a treasure to preserve in the freedom and integrity of the profession. Dr. Wesley Bourne, of the Department of Anaesthesia at McGill University, also replied for the guests. He represented the American Society of Anaesthesiologists and the Canadian Anaesthetic Society, as well as his own university. By the three he had been charged to congratulate the Association of Anaesthetists on this occasion. He also conveyed the thanks of the anaesthetists of the fighting Forces of the U.S.A. and Canada for the courtesy extended to them during this war. Two weeks ago, he observed, a meeting of anaesthetists, dentists, surgeons, and physicians was held in Boston to celebrate the 100th anniversary of the use of ether in a surgical operation.

COMBATING RHEUMATISM IN SWEDEN

Prof. J. A. Höjer, chief medical officer of the Royal Swedish Health Department, recently described at a meeting of the Empire Rheumatism Council the campaign against rheumatic diseases in Sweden. The latest development was the building of a research institute in Stockholm which it was hoped would be opened early in 1948. The Swedish Research Council, analogous to the M.R.C. in Great Britain, had elected a sub-committee on research in rheumatic diseases. The various hospitals in Sweden devoted in whole or in part to rheumatic diseases worked to a central plan. Planning first began about 1934, when 656 beds were specially set aside for rheumatic patients; in 1941 a further 1,300 beds were provided, and in 1945 a further provision of 2,000 new beds was made. The basis of the latest plan was the reports of practitioners on all the rheumatic cases of which they had had knowledge in 1943. Nearly 1,400 doctors responded (80% of those expected to do so); the total number of cases reported was some 56,000. A calculation was made of the number of these requiring hospital care, the patients being divided into four categories: (1) acute arthritis, (2) chronic arthritis, (3) arthrosis, and (4) sciatica and miscellaneous rheumatic conditions. It was considered that a 60 days' stay in hospital should be allowed on the average for cases of acute arthritis, 90 days for chronic arthritis, and 40 days for the cases falling into the third and fourth groups.

It was proposed to relieve the hospitals by provision for convalescence and, especially in view of the increased longevity and the liability of old people to develop rheumatism, to increase the accommodation for chronic cases in the aged. A Swedish Association for Combating Rheumatism had been formed recently and worked in co-operation with the employers' and labour organizations, with the Swedish Medical Association, and with bodies of social workers.

CONFERENCE ON MENTAL HEALTH

The National Association for Mental Health is now being incorporated by the formal amalgamation of three voluntary organizations, the Central Association for Mental Health, the Child Guidance Council, and the National Council for Mental Hygiene. These three bodies, during the past few years, have been provisionally amalgamated, and most of their work has been carried out by the Provisional National Council for Mental Health. With incorporation the whole field of voluntary mental health services in England and Wales will be brought under one head. To signalize this event a conference on mental health is being held at Caxton Hall, Westminster, on Nov. 14 and 15. It will be attended by many representatives of local authorities and voluntary organizations from all parts of the country. The first morning session will be devoted to the application to the civilian population of war-time experience of neurosis and backwardness in the Forces, and the employment of the mentally and emotionally handicapped, the speakers being Dr. J. R. Rees and Dr. T. F. Main, with Prof. J. M. Mackintosh in the chair. At the afternoon session the Minister of Health will give a short address, and Prof. Aubrey Lewis will speak on community care in relation to the extended powers of health authorities under the new National Health Service Bill. The subjects for the morning session on Nov. 15 are the care of the homeless child, and juvenile delinquency (Miss Lucy G. Fildes and Miss Margery Fry). At the afternoon session Miss Norah Gibbs and Dr. John Bowlby will speak on the integration of the psychological services under the new Education Act, and on the future role of the child guidance clinic in education and other services. Applications for tickets and all correspondence should be sent to the Conference Secretary, 39, Queen Anne Street, London, W.1. (Telephone: Welbeck 1272.)

Blood donors in Scotland gave 7,888 pints of blood in the quarter ending June 30, 1946. This was an increase of 657 pints compared with the previous quarter and sufficed to balance the output of blood and plasma requested by hospitals from the Scottish National Blood Transfusion Association. Increased demands were made on the Blood Transfusion Service, particularly by the general hospitals, for liquid plasma, and the amount issued rose from 839 to 1,448 pints. The amount of whole blood used was 4,136 pints compared with 4,094 pints in the previous quarter. During August the Glasgow and West of Scotland Blood Transfusion Service despatched to hospitals in the area 637 pints of whole blood and 471 pints of plasma (representing 1,000 pints of blood)—a total of 1,657 pints.

Reports of Societies

UNDERGRADUATE TRAINING IN OBSTETRICS AND GYNAECOLOGY

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on October 18 Mr. JAMES WYATT, the President, delivered an address from the chair on the future training of the undergraduate. At the beginning of the meeting a tribute was paid to Sir Comyns Berkeley and Dr. Watts Eden, former Presidents of the Section, who had died since the previous session.

Mr. Wyatt said that obstetrics and gynaecology was much more compact than medicine and surgery. Those specializing in it had been remarkably drawn together by the formation of the Royal College of Obstetricians and Gynaecologists, and it would not be difficult with the aid of that College to arrive at an agreed scheme of training which would bring in all the schools. The aim of undergraduate training was primarily to make a good general practitioner. If in the course of his training the student discovered that he had specialist aptitudes any special training should not be started until he was thoroughly grounded in general medicine. Specialists who set examination papers were often inclined to forget that the student ought to have a good general knowledge. In future a certain amount of notice would be taken of reports on the student's ability during his period of training by the chief under whom he had been trained. Mr. Wyatt thought also that there should be a standard textbook for undergraduates. This would not prevent students who wished to do so from applying themselves to the full literature of the subject, but it would save the less learned from absorbing a great amount of unnecessary knowledge at this stage of their career.

Obstetric Teaching Beds

In his own student days there were no obstetric beds in the hospitals for teaching, and not until after the first World War was it decided that all students must spend a month in a lying-in hospital or in the lying-in wards of a general hospital before they went on the district. This stimulated the majority of teaching hospitals to open up a number of lying-in beds, and it was not until those beds were opened that any sort of antenatal examination was carried out. Nowadays the district was a thing of the past. The majority of students learned their midwifery in a lying-in hospital, and this was a pity, because some valuable knowledge of the home life of patients was learned in domiciliary midwifery. He hoped it would not be long before all teaching hospitals would have sufficiently large units to enable their students to receive all their obstetric training under the control of the teaching hospital instead of having to go off to another hospital. It was not just training in actual delivery that was important; the training in the antenatal department should by no means be neglected.

In gynaecology the student learned more of value in the out-patient department than in the wards. Here he learned to value the psychological approach. Attendance in the operating theatre should be restricted. From some points of view the operating theatre was important; it afforded the opportunity of careful pelvic examination under anaesthesia, but the watching of long operations should be confined to those who were taking an active part in the particular case. It was also important that such a student should see the same case three or five weeks later in the follow-up department to learn the actual results of operation. When it came to detail in gynaecology, how much intricate knowledge of the pelvis should the student be expected to know? It would be an advantage if he was expected to know more about the physiological aspect of normal functioning. What amount of morbid anatomy was necessary? Was it necessary for him to be asked questions as to all the different types of ovarian tumours? It seemed much more important that the student should recognize if the patient had an ovarian tumour and whether it was innocent or malignant. Any major operative technique was not wanted.

Reduction in Number of Cases

In some discussion following the President's address Dr. J. P. HEDLEY said that the education of the medical student had

recently been considered by the General Medical Council, which was recommending that medicine, surgery, and obstetrics and gynaecology should each have a full six months. It was also proposed that the number of cases a student had to attend should be reduced from 20 to 12, and that two individuals could attend the same case. Dr. MALCOLM DONALDSON said that once it was recognized that a man must have postgraduate training before he took on obstetrics in the new service he could cut down a little of the obstetrics in his undergraduate training and even more of the gynaecology. The latter was best taught in the out-patient department. "On methods of teaching he felt that the value of the film had been neglected. He was a member of a committee which was approaching the University of London on this subject. Much excellent teaching could be given by means of film strips.

Dr. A. J. WRIGLEY said that care must be taken not to put an entirely specialist view before medical students. It was very important to direct the student's attention to the general condition of the pregnant woman, not merely to the manner of presentation and such details. Too often in cases, for example, of ante- or post-partum haemorrhage there was no general assessment of the patient. Very few people had heard of postnatal clinics, which were very useful and in which it was possible to teach a great deal of preventive medicine. At examinations questions were not sufficiently asked about the postnatal condition, and the infant got no attention, the care of infants in many hospitals being handed over to the paediatrician. In gynaecology, more perhaps than in any other branch of medicine, specialization was in less and less demand. The conditions seen in the gynaecological out-patient department were closely linked up with general medicine. In cases of amenorrhoea and the like, as a rule, the general condition was more important than abnormalities of the pelvis. Teaching in gynaecology was best given in the out-patient department. If a student spent too much time in the gynaecological ward he was apt to think of gynaecology as a department of surgery. If a student was going to be three months in his department he would put him for two months with the out-patients and only for one month in the wards.

The Future G.P. and Midwifery

Prof. F. J. BROWNE said that he had long felt that as teachers of undergraduates they were at the mercy of examiners in the final examinations and unable to teach how and what they wanted because their first duty was to try to get the students through the final. The undergraduate should be taught fundamental principles; it was impossible to teach him technical details of the management of cases which the rest of them needed a lifetime to learn. After a student had finished his course in the school there should be an internal university examination dealing with fundamental principles and giving the man his degree, and then during his postgraduate and pre-registration year, when he was serving an internship, he could learn certain technical details in the only way in which they could be learned, namely, by practice. Prof. Browne said that there would never come a time when women would not want to be attended by their own general practitioners in the greatest crisis of their lives, and there would always be men just qualified and going out into practice who, being popular with their women patients, would see them through their confinements. Short of the introduction of an entirely new principle into medicine, these men would attend cases without having any higher qualification. It was essential, therefore, to give a very small amount of training to the undergraduates who might have to take these responsibilities. He was sorry to hear of the reduction from 20 cases to 12. It was important to have both number and variety of cases to give the student the necessary experience. When the student went into practice it was not normal cases he would customarily attend; these would be attended by midwives. He disagreed with the President as regards attendance at operations. It was very useful for the students to see minor operations of the kind which they might have themselves to do in practice. In the operating theatre they had the opportunity of carrying out bimanual examinations under anaesthesia, and they saw the living pathology. He could not agree that the film was valuable in education save in the illustration of a rare condition which would not be seen in six months' clinical work.

Prof. W. C. W. NIXON, speaking with regard to the use of films, took a contrary view to that of his predecessor at University College Hospital. The use of films and of photography in teaching was one respect in which the Americans led. As for social obstetrics, he suggested that students should go to the borough clinics and see pregnancy more "in the round." Mr. ARNOLD WALKER said that there was a large pool of surplus cases in municipal general hospitals which could be used for students. Mr. V. B. GREEN-ARMYtage deplored the tendency in examinations to keep to the book. If they went outside the book the students were at once "stumped" from the point of view of answering questions. One departure which might be made was an interchange of teachers in the various schools. Students got bored with one set of teachers and the same rigmarole.

South African Practice

Prof. JAMES BLACK, who holds the chair of obstetrics and gynaecology in Witwatersrand University, said that his students last year on the average delivered 27 cases, and they saw including normal and abnormal ones. He usually gave them three weeks of practical obstetrics and then, after a six month interval, a further six weeks. He had had the advantage of 17 years in general practice before he took up the speciality and knowing the general practitioner's exigencies, he tried to make the course as practical as possible. Next January a student would come into force in the Union whereby no student would be allowed to practise until he had had a year's internship in hospital, four months of such year to be devoted to obstetrics and gynaecology. He was all in favour of teaching by film. He had been doing this now for six or seven years. He believed too much time was wasted in watching operations while the student should be studying cases he would encounter in general practice.

Dr. G. DICK REID commented on the absence of teaching of normal labour. How were students to be expected to acquire knowledge of normal cases? How many lectures were devoted to the procedures of normal labour? Mr. WILLIAM GILL said that there were men teaching in London who did devote some time in their lectures and demonstrations to teaching the conduct of normal labour, and there were obstetricians who had sat through normal labours. Dr. BEATRICE TURNER said that 12 cases properly attended were far better than 20 in which the student just went in to deliver the head. Lectures, interesting as they might be, should be kept to a minimum before or after the obstetrics course.

A speaker who described himself as the youngest graduate present regretted that he had had no opportunity of following normal deliveries. An "embryo teacher" declared that the reform of the examination system was long overdue. Examination was the "dead hand" against all that the teacher tried to do for his students. The student became more and more technically minded, interested in technical detail, which belonged to postgraduate instruction. Another speaker suggested that more midwifery should be seen at the expense of gynaecology. Attendance at the gynaecological out-patient department should be synchronized with the teaching of midwifery. Thus the period of midwifery could be doubled at the expense of ward gynaecology.

Mr. WYATT, in replying to the discussion, said that in teaching hospitals provision would have to be made for teaching how to deal with cases of abortion.

A clinical meeting of the Medical Society of the L.C.C. was held at Hammersmith Hospital, on Aug. 8, when cases were demonstrated. Prof. Grey Turner introduced a discussion on cases of: A patient thirty-four years after transplantation of ureters for total epispadias with incontinence. Cases seven years and five years after treatment of epithelioma of mouth and C operation for removal of neck glands. Malignant melanoma of eyelid with massive secondary invasion of neck glands; patient free from recurrence six years later. Dr. Scadding discussed a case of sarcoidosis and asthma, urticaria, and transient pulmonary infiltrations: a case for diagnosis. A case of chronic uraemia associated with pregnancy was described by Dr. Hollings and Prof. Keel. Mr. Franklin reviewed the history of a case with carcinoma of the sigmoid colon, pulmonary tuberculosis, and gastric ulcer.

Correspondence

The Plebiscite

SIR,—The profession in this country has now to make the most momentous decision in its history. The point at issue is whether medicine shall remain a free profession or become gradually but inevitably a branch, at one remove, of the Civil Service, whose primary duty will be to the Government which pays and controls it. This question is not directly posed by the present vote but is implicit in it. If it goes in favour of entering the suggested "negotiations" about regulations the implication will be that we are willing to enter the new Service, or, at any rate, are resigned to the prospect. Are we?

Parliament has declined to insert in the Bill several points which we have repeatedly declared to be essential to a good service. I will deal with only one of them because I think it is crucial. The future of the general practitioner would be fixed or ever if we accept that all medical practices shall be the property of the State. It is a sinister sign of the times that in many quarters it is considered to be almost a crime that the individual citizen should possess something he can really call his own. I was brought up to believe that it was a good thing for the individual and for the community that by hard work, enterprise, and thrift a citizen should make good in a career carved out by himself, and that it was something to be proud of if, at the end of his career, he had made something he could call his own and which he could pass on to a successor of his choice. This is, however, repugnant to the people who now think themselves capable of controlling our destinies, and their intention was made quite clear when it was decided that in future there should be no private property in the goodwill of practices, however honestly and laboriously earned. It should be noted that what is proposed for doctors can easily be applied to any man who has built up a business. And what a farce he offers of compensation is! Sixty-six millions of public money is to be given to people who don't need it, because in normal times they could get the price of their goodwill in their own time and without a penny of public assistance. Is it not clear that the intention behind this alleged "generosity" is to acquire complete control of the profession which is as yet "not ripe for it"? Once this is done the "part salary and part capitation" can easily be made into "more salary and less capitation" until the eventual aim (not at all disguised) of the Socialist is attained and the ripening process is complete. I am aware that this prospect has no terrors for some medical men—those who are more Socialist than medical, and those who hanker after "security." Yes, they can have security. A bird in a cage has it, and there will be as little prospect of escape for the one as for the other. There are also the wavering section who plead that it is "inevitable." Nothing is inevitable until it has happened. If Mr. Churchill had been "one of the old inevitables" we should now have been a part of the German Reich.

If one needs further confirmation of this desire for complete control look at what is to happen to the specialists and consultants. The hospitals are to be confiscated, and no specialist or consultant is to have a hospital appointment who is not a member of the Service. And, so that no avenue of escape shall be left, the Minister can take over compulsorily any private hospital or nursing home.

There are many other points in the Bill which show what are the intentions of an arbitrary Minister who has no use for negotiations, but these are comparatively trivial compared with the one I have mentioned. I believe that if the doctors lose the control of the goodwill of their practices they will have surrendered the citadel of our case against the Bill, and their birthright of professional freedom. I hope, therefore, that the answer to the plebiscite will give our leaders the emphatic backing they need if they are to take a strong line. They cannot be expected to do so unless the answer is unmistakable. What would be the consequences if the answer is as I hope it may be? The Minister will be faced with a situation in which he will have a supply of doctors quite inadequate to enable him to fulfil his promise of a first-class medical service everywhere. There will be no "strike." You can only strike against conditions

already accepted. The public will still get the services of their doctors and it will be for the Minister to explain how the bills are to be paid out of the compulsory contributions he has already collected. I am well aware that to take the course I am hoping for means preparing for a stiff fight. Will the profession rise to it? If not, then it will be tacitly confessing that the Service it has told the public was unacceptable to the profession, and had for their patients, must be accepted because the doctors think that a poor Service is good enough for the public—or, at any rate, is not worth fighting about.

I may be told that the history of the fight over National Health Insurance in 1911-12 shows that the profession cannot be relied on to stand to its guns. The circumstances are not at all comparable. Then we had won most of what we fought for but were too stupid to claim a win on points. This time we have won nothing of any consequence. Every alleged "concession" made by the Minister "has strings to it" which can be tightened up in his own good time. I may be told that it is all very well for an old man who has nothing to lose to incite others to undertake a momentous and difficult struggle. It is true that I, personally, have nothing to lose, but the profession I have served all my life has everything at stake—including its soul.—I am, etc.,

London, S.W.7.

ALFRED COX.

SIR,—With regard to the plebiscite about to be taken I can foresee that a good deal of misunderstanding may arise over the interpretation of the answers given. The suggested wording is whether negotiations on regulations under the National Health Service Bill should take place with the Minister of Health. According to the Bournemouth memorandum a vote upon this question will be tantamount to acceptance or rejection by a majority of the profession of the principles and essential structure of the Bill. Surely this is a quite unwarranted interpretation and reads into the question much more than is asked.

Should the majority vote against negotiations it is reasonable to assume that they will refuse to work the present Bill. If the majority are in favour of negotiations, this can only be interpreted to mean that they want to see the final terms and conditions of service before coming to a definite decision. If the Council of the B.M.A. want to know whether the medical profession will accept or reject service under the Bill if enacted in its present form, they must ask this as a direct question either now or at a later date. To interpret the voting on the suggested plebiscite as an answer to the above question can only lead to confusion.—I am, etc.,

London, W.1.

L. G. SCOLLAR.

Fate of Parliamentary Regulations

SIR,—In view of the forthcoming referendum to the profession regarding action to be taken in face of the present position of Mr. Bevan's Bill, I should like to press again my conviction that the only decision which doctors should consider now is whether they, as individuals, will or will not take service when the Act reaches the statute book. My conviction is based upon an analysis, which I submit herewith, of a review of the fate of Regulations (that is "Statutory Rules and Orders") issued by the Ministry of Education since the present Government entered upon its steam-roller course in the House of Commons in October, 1945.

In his masterly exposition of the Bill on the Second Reading (Lords' Hansard, October, 1946) the Lord Chancellor, Lord Jowitt, sought to reassure the medical profession with the statement that while he acknowledged that the Minister is to enforce the provisions of the Bill "by a regulation-making power" the profession was safeguarded by the fact that "Every single one of the regulations which he makes has to come before Parliament, and either must receive affirmative approval, or can be quashed by a resolution of either House." How complete is the scope of this regulation-making power was clearly demonstrated in the White Paper in Section 33. It is there set out: "The Minister is empowered to make regulations governing the qualifications, conditions of service, and remuneration of any, or all classes of hospital staff, as of the staff engaged in any other part of the Health Service." I submit, Sir, that while this practically unrestricted power of making

regulations "governing the qualifications, conditions of service, and remuneration of every person in the Health Service" remains reserved to the Minister, the safeguards of which Lord Jowitt made so much are wholly illusory.

In a Parliamentary answer to me (*Hansard*, Oct. 22, 1946) the House of Commons was informed that since the passage of the Education Act, 1944, the following regulations, circulars, and administrative memoranda have been issued by the Ministry of Education: regulations, 35; circulars, 145; administrative memoranda, 186. I append a record of the ultimate fate of the only regulations under the Education Act, 1944, which have been in fact challenged in debate in the House of Commons since Oct. 18, 1945, up to June 4, 1946: (1) Regulation under Statutory Rule and Order 1945 No. 636—Motion for annulment rejected after debate (Oct. 18, 1945). (2) Regulation under Statutory Rule and Order 1945 No. 709—Motion for annulment withdrawn (Oct. 24, 1945). (3) Regulation under Statutory Rule and Order 1946 No. 352—Motion for annulment rejected. (4) Regulation under Statutory Rule and Order 1946 No. 630—Motion for annulment rejected.

The regulation-making power under Mr. Bevan's Bill is even more universal than in the Education Act. It is to be remembered that Statutory Rules and Orders, unless challenged by one or other of the Houses within a prescribed period, automatically become law.—I am, etc.,

House of Commons.

E. GRAHAM-LITTLE.

Health Service Bill

SIR,—We have already contributed to your columns a letter about the Health Bill (Sept. 21, p. 439) deploring the loss of liberty which we shall all suffer when it becomes effective. Some doctors appear to be unable to recognize the dangers resulting from this loss of liberty, others are apathetic, and some say quite honestly their primary concern is with the regulations, financial and otherwise, by which the Bill will be worked. To the latter we should like to point out that, whereas the Minister will no doubt offer reasonable and attractive terms to medical practitioners to join the new Service, we shall have no guarantee or safeguard that in the future conditions will remain so reasonable and attractive. When we have renounced our freedom and placed ourselves unreservedly in the hands of the Minister, what will prevent him, or his successors in the years to come, from scaling down salaries and pensions on the grounds of national economy? If in the future some of those who are now prepared to join the Service become dissatisfied with the conditions as they may then be, they will have to be very brave to give vent to their dissatisfaction, for under the Bill, if they come into conflict with the Ministry which employs them, they will find that the Minister may be their ultimate accuser, jury, judge, and executioner, and the choice will lie between toeing the line and dismissal and ruin.

The recent dispute between the doctors and the Minister about the N.H.I. capitation fee is an obvious warning to the profession. The Minister refused to apply the recommendations of the Spens Report or to negotiate with the Insurance Acts Committee. His attitude was dictatorial and arbitrary, and it was not until the doctors forced his hand, by showing that the majority were prepared to resign rather than submit to this injustice that he conceded the point. Once the Minister has the profession completely in his power it will not be possible to voice such grievances or obtain redress. We hope that those who think the regulations of the new Service are the subject for consideration (and there are many who seem to think so) have even written letters to the *Journal* roundly declaring as much) will realize before it is too late that it is impossible to buy security at the expense of freedom, even if it were desirable to do so, as some seem to think it is. We do not suggest that the profession should refuse to co-operate in a State Medical Service—the Bill is in many respects excellent—but we do hope that they will be adamant in their refusal to work the scheme until the objectionable and dangerous clauses are removed. It is not our freedom only which is at stake. If we collapse the whole framework of civil liberty, already seriously undermined, will be much further weakened.—We are, etc.,

ZOE HARRIS.
PAUL HARRIS.

Errors in Regard to Goitre

SIR,—The original paper (Sept. 28, p. 449) by Drs. L. Keynes, and Piercy, has successfully challenged and stimulated thought. The vast experience upon which the writers for their paper has been mainly gained from a surgical and tends to be fundamental and factual within this application. As a physician with medical leanings, one cannot fail to be impressed by the clinical usefulness of methyl thiouracil in long periods, admitting its limitations and incidence of toxicity. The more recent treatment of thyrotoxicosis with radioiodine by mouth (Chapman and Evans, *J. Amer. med.*, 1946, 131, 86) still further widens the effective field of the drug.

Surgery will, nevertheless, always have a useful and indispensable place in this field. One wonders, however, whether the incidence of carcinoma superimposed on goitre, for which figures in different pathological centres appear to be variable, should be unduly stressed in the absence of indications for surgery. As to the diagnosis of thyrotoxicosis my experience is similar to the much greater one of Robertson, namely, that the basal metabolic rate is of greatest value, and in the absence of an absolute or relatively raised rate thyrotoxicosis should not be diagnosed. For I am impressed by the considerable number of patients who meet with of all ages examination of whom reveals enlarged thyroids of which they have been usually unaware, frequently have anxiety symptoms, but show no real evidence of thyrotoxicosis. Further, such evidence does not develop during years of observation. The frequency of enlarged thyroids and the ineffectiveness of thyroidectomy are well recognized in the condition of "effort syndrome" or D.A.H. (disorder of action of the heart), a recognized neurosis. In view of the emotional factor in the aetiology of thyrotoxicosis and the possible hypothalamic mechanism, it is difficult to see why patients do not go on to thyrotoxicosis. The inherent responsiveness or unresponsiveness of the thyroid gland appears to be a factor. The iodine intake of these sporadic cases appears normal.—I am, etc.,

London, W.1.

S. LEONARD SIMPSON

Diagnosis of Intestinal Amoebiasis

SIR,—The letter by Dr. K. R. Hill (Oct. 19, p. 589) on "vocative emetine" in the diagnosis of intestinal amoebiasis cannot be allowed to pass unanswered. The standard works on the subject fail to show any reference to this method of diagnosis, and one can only assume that it is based on a taken analogy with the "provocative" dose of N.A.B. in the serological diagnosis of latent syphilis. However, the problems are obviously wide apart in principle. Whereas the latter involves a complex complement-deviation reaction, the former is no more involved than the action of emetine on the amoeba; and amoebae which are so scanty as to be difficult to demonstrate will surely be made even more scanty if the patient is given emetine. So many inaccurate statements have been made on the subject of diagnosis of this condition that to recall a few elementary points, even at this stage, is almost excusable.

Apart from a suggestive history and clinical findings such as a thickened sigmoid or caecum, the only absolute criterion is the demonstration of the amoeba under the microscope. In the acute or subacute condition, the vegetative amoeba is always found in the faeces or bowel scraping obtained by sigmoidoscopy. In the "quiescent" phase, it is the cyst which is found, but only comparatively rarely, and it is no more a matter of luck whether any one specimen contains cysts than it is that a series of twenty, or thirty stools; but all these may be negative and only a third specimen positive; in fact, where there is one to ten, the production of an artificial diarrhoea by giving the patient salts does not seem to make the problem any easier. In military practice, the patient is put off sick and nothing else to do except provide the laboratory with specimens. In civilian practice this is impossible because no patient will bring thirty consecutive specimens on thirty consecutive days, or stay in hospital for a month merely to establish a diagnosis in a condition which is not giving him much trouble. At this point there are two solutions to the problem, which

The Twenty-Lozenge Pack

Penicillin Lozenges A & H are issued in glass tubes to prevent inactivation of the penicillin by atmospheric moisture.

The number of lozenges contained in the tube (TWENTY) provides the most suitable package to meet the needs of individual treatment prescribed by the physician. Not only does it tend to eliminate waste but it assures the prescriber that the lozenges will not have time to become inactivated by exposure to a moist atmosphere before the prescribed treatment is completed.

Penicillin Lozenges A & H are indicated for the effective local treatment of bucco-pharyngeal infections.

In tubes of 20 Lozenges, 1/9.

ALLEN & HANBURY LTD LONDON, E.2

The Caplan ELECTROCONVULSANT Apparatus

An Improved Lightweight Instrument for the Psychiatrist.

The advantages of this new apparatus are that it is simple and quick to operate, it is absolutely safe both for patient and doctor, and it is light in weight and handy in size. It is robust so that it stands up to the strain of routine practical use, and it has been designed in such a way that the risks of technical breakdown have been reduced to a negligible minimum.

Its improved design is based on the rejection of the idea that the convulsant dose can be calculated in advance by measuring the resistance of the patient. Circuits for the measurement of this resistance have therefore been eliminated, thus simplifying not only the construction but also the working of the apparatus.

A new type of electronic time switch is incorporated, which gives an entirely safe and reliable performance.

An arrangement of push button switches prevents accidents to the patient or the nursing staff while the electrodes are being adjusted, and at the same time reduces the actual procedure of administering the shock to its simplest terms. For this reason, and also because the apparatus is so small and easy to handle, the treatment time is greatly reduced.

Standard Model. 200/250 volts, 50 cycles A.C. The output is 40-150 volts for 0.1-1.0 second. It is housed in a strong metal cabinet measuring 9 in. x 9 in. x 8 in., and weighs 16 lbs. Price, 40 guineas. One year's guarantee. Models are available for immediate delivery on 14 days trial.

The Delicious Nourishing, Energising Vitamin Food for Infants, Children & Adults —at all Seasons

BY presenting valuable nutritive elements and important vitamins in a delicious form, 'Vimaltol' offers special advantages in everyday practice to the physician. With its delightfully sweet orange flavour 'Vimaltol' is readily acceptable to every patient.

'Vimaltol' is made from specially prepared malt extract of high protein content, yeast—one of the richest sources of Vitamin B₁—and Halibut Liver Oil, an important source of Vitamins A and D. It is also fortified with additional vitamins and mineral salts, and is deliciously flavoured with orange juice.

'Vimaltol' is standardised to contain in each fluid ounce: 648 international units of vitamin A and 1390 of vitamin D, also 0.3 milligrammes of vitamin B₁, 4 of Niacin (P.P. vitamin) and 4.8 of Iron, in a readily assimilated form.

'Vimaltol' has, therefore, an important therapeutic value where the deficiency of certain essential food elements in the dietary has resulted in abnormal conditions. Its regular use assists the development of the growing organism and the maintenance of correct metabolism while raising the general resistance against infection.

'Vimaltol' can be prescribed with advantage at all seasons, and for patients of all ages.

**VITAMIN C B.D.H.***(Ascorbic Acid)*

There is increasing evidence that vitamin C plays an essential part in most of the processes of protein metabolism in the body. It is associated with the growth, renewal and structural maintenance of connective tissues, the organic matrix of bones and teeth, formation of red blood cells and haemoglobin and possibly with the formation of antitoxins and antibodies, thus playing a part in protecting the body from infection and anaphylaxis.

Vitamin C B.D.H. is available for oral and parenteral use in tablets and ampoules in strengths suitable for prophylactic or curative treatment for all the purposes indicated above. Further details available on request.

PHARMACEUTICAL SPECIALITIES (MAY & BAKER) LTD., DAGENHAM

an academic and practical. The academic solution is very satisfactory. The patient asks, "Have I, or have I not, amoebic dysentery?" and one is bound to answer, "I do not know." The practical solution is to tell the patient to return immediately there is any recurrence of the diarrhoea, and if it is in fact due to amoebic dysentery one will always find the vegetative form of the amoeba. Of course, there are various objections to this procedure, among which is the fact that the patient may in the meantime develop an acute hepatitis, and this in no way affects the general principle. In addition, one may resort to stool culture on special media and, I understand, there is some work being done on a complement-fixation reaction.

Tropical medicine, like all other branches of medicine, consists of a structure of knowledge and experience based on an appreciation of fundamentals, among which is the action of retine on the amoeba of dysentery. That so many misconceptions have arisen is, I feel certain, due to the fact that a large number of doctors during the war, through no fault of their own, have had thrust upon them a subject which they have rarely, if ever, had to consider before.—I am, etc.,

Novel Method of Digital Traction

SIR,—Dr. MacLeod (Oct. 26, p. 614) is incorrect in thinking that nail traction in the treatment of fractured phalanges is novel. While in charge of the fracture department at Guy's Hospital I used this method for many years as the routine treatment for oblique fractures of the phalanges. The method was described and illustrated in an article on "Fractures of the Upper Limb" (*Guy's Hospital Reports*, 1921, 71, 360), and on several other occasions. In most cases I found it possible to perforate the free edge of the nail painlessly and without anaesthesia, and a fine salmon gut suture was my material of choice for traction. The method is one I found of great use, and when established the traction, which in my practice was maintained via a rubber "accumulator," is quite painless.—I am, etc.,

Classification of Psychological Disorders

SIR,—The conclusions of Dr. Dalton Sands in his most instructive and admirable article on "Electro-convulsion Therapy in a General Hospital" (Aug. 31, p. 289) seem perfectly logical. However, in the cases of "anxiety state" or "anxiety neurosis" to which Dr. Frederick Dillon refers, supposed elements of guilt and tension from aggressive impulses may be quite wrongly interpreted by inexperienced psychiatrists when the anxiety is due to perfectly obvious and innocent reasons which they have not ascertained, the real elements of guilt and aggressive impulses lying completely elsewhere.

Under these circumstances, as Dr. Dillon rightly points out, not only are statistical studies on psychological disorders, in the present state of our knowledge, very apt to be misleading, but they may be wholly erroneous, and will continue to be so unless the whole question is considered *de novo*; and it follows that any knowledge based on such false premises is false knowledge.—I am, etc.,

London, N.W.11.

A. LIONEL ROWSON.

Painful-feet Syndrome

SIR,—I was most interested in Surgeon Commander Page's excellent article on painful feet (Aug. 24, p. 260). On the capitulation of the Dutch East Indies in March, 1942, 3,500 Allied prisoners, mostly British, were interned in a camp at Tandjong Priok, Java. The painful-feet syndrome developed in July, and by October a conservative estimate of the number of cases in the camp would be 1,000. They presented all the signs and symptoms of Commander Page's cases with the exception that gangrene was not found, possibly due to the warm climate.

Certain canteen supplies were allowed into the camp in October, and it was found that a daily ration of 100 g. of boiled kachang idjau (a small type of green pea) had a most beneficial effect on the condition, resulting in complete relief

of symptoms in approximately 80% of the cases within two weeks.

At a later date a liver extract (crude), obtained from Dutch sources outside the camp, was being tried out in the treatment of patients with "blurred vision," many of whom at the same time were suffering from burning feet. It was noticed that while it proved of no apparent value in the former complaint it completely cured or greatly improved the condition of those patients who had painful feet. Following on this discovery 2 ml. of the liver extract, of which available quantities were very limited, were injected intramuscularly at intervals of two to three days in a few very persistent cases of painful feet, and rapid cure resulted.—I am, etc.,

Legal and Medical "Insanity"

SIR,—In your correspondence on crime and insanity, Dr. D. Stafford-Clark (Oct. 26, p. 627) very relevantly points out that nebulous speculations on right and wrong are of little practical value, and rightly draws attention to the problem of the psychopath, a problem frequently encountered by military psychiatrists during the war. Some of the difficulties which arise on how best to deal with these medico-legal problems surely arise from the different psychology of psychiatrist and lawyer. The latter often views the problem too logically; to say that if a lunatic kills because he hears the voice of God he is not culpable, as he would be expected to obey His voice, but that he cannot be similarly excused if it is only the voice of Mr. Smith—an argument once put forward—is good logic, but poor psychiatry. For it is the great effect aroused in a paranoid, or the impulsiveness of the schizophrenic, which results in the crime, irrespective of the cognitive side.

I believe I am right in saying that the McNaghten Rules were formulated on the legal tenet that a crime can only be excused if the prisoner's state of mind—like that of an infant—could not form criminal intent. The law ignores the fact that insane impetuous behaviour can occur, although full insight into the quality and illegality of the act is preserved. Therefore, while admitting that irresistible impulse in a sane individual cannot be accepted as a plea while there is no means of proving that it was irresistible, one would think the McNaghten Rules could safely be extended to a third clause, i.e., that if there is gross disease of mind and a consequent inability to control conduct, this would justify a plea of guilty but insane. The matter is largely academic, and if capital punishment goes, this plea will probably never be put forward. If the lawyers are too logical, the same reproach is not always applicable to the psychiatrist. I have heard it urged that the obsessional neurotic is not culpable because the cause of his behaviour is unconscious—a complete irrelevancy, as what matters clearly is not the causation, but proof that control of the impulse is genuinely impossible. Neither do appearances in the witness-box to testify that for years successful forgery was performed in a state of unawareness, or similar sincere but somewhat unlikely hypotheses, help to reassure the legally minded. Yet in the case of the psychopath, as the *Times* states, medical is ahead of legal opinion.

Psychopathy is hard to define, but if we cease to try and find a formula whereby the psychopath can be regarded as not culpable—an impossible and dangerous doctrine—and treat psychopathy as a form of insanity, surely a practical solution lies to hand? A lunatic, like a psychopath, is hard to define, but all we are called upon to do when certifying is to produce evidence of unsound mind, and that the patient in consequence needs "care and treatment for the sake of himself and others." Thereupon he receives an "indeterminate sentence," only as it is to a hospital and not a prison the idea is tolerated. Why cannot the criminal psychopath be dealt with similarly?—i.e., where the court has grounds to regard a prisoner as a true psychopath, let a suitably constituted board certify him as such, and commit him to a form of special institution, with powers to release him if at any time it is felt this can safely be done. As with the insane, borderline cases might not be certified, whereas obvious cases, on whom imprisonment has not the slightest effect, would not be turned loose on society. Nor would a clan of individuals, quite a number of whom are

genuinely desirous of but incapable of inhibiting their impulses, be subject to spells of useless and cruel punishment. For the very same temperamental defects which lead many psychopaths into breaking the law also render them particularly unamenable to ordinary prison discipline. In consequence they are a source of great trouble to the prison staff, and often become severely depressed. It is very much to be hoped that the Prison Reform Bill will make some alternative to ordinary imprisonment where at least the above types of psychopath can be sent.—I am, etc.,

London, W.1.

W. LINDESAY NEUSTATTER.

SIR,—Most psychiatrists will surely agree with the timely observations of Drs. McCluskie and Cuthbert (Oct. 12, pp. 555-6).

(1) It is hardly credible that, in England to-day, the only legally accepted criteria for the diagnosis of mental illness in criminal trials are those formulated over one hundred years ago in the McNaghten rules (1843). It is doubtful whether the latter were even at that time in harmony with contemporary medical opinion; but the tremendous advances made in the twentieth century in psychiatry and in the understanding of criminal psychopathology have been completely ignored by the law. To mention but one gross misconception, the rules assume throughout that an insane person is necessarily "afflicted with insane delusion." To quote the report submitted by the Medico-Psychological Association to the Committee on Insanity and Crime (1924): "Unsoundness of mind is no longer regarded as in essence a disorder of the intellectual or cognitive faculties. The modern view is that it is something much more profoundly related to the whole organism—a morbid change in the emotional and instinctive activities, with or without intellectual derangement. Long before a patient manifests delusions or other signs of obvious insanity he may suffer from purely subjective symptoms, which are now recognized to be no less valid and of no less importance in the clinical picture. . . ." (Cmd. 2005.) The report adds that the McNaghten rules "do not now appear to be considered in Scotland," and quotes in this connexion Lord Dunedin, Lord Justice-General (1907), as follows: "It is quite certain that what may be called the scientific view on insanity has greatly altered in recent years, and Courts of Law, which are bound to follow, so far as they can, the discoveries of science and results of experience, have altered their definitions and rules along with the experts. . . ." It is fortunate indeed that contemporary legislation on the treatment of mental illness or, for example, on matters of public health, is not similarly based on the medical knowledge of over a century ago.

(2) It is time the concept of the "uncontrollable impulse" were given legal recognition, as recommended by the Committee on Insanity and Crime: "It should be recognized that a person charged criminally with an offence is irresponsible for his act when the act is committed under an impulse which the prisoner was by mental disease in substance deprived of any power to resist." This conception is by no means a new one: Pinel (1801) referred to *la folie raisonnée*, a mental illness in which reason and intellect were unimpaired; and J. C. Prichard (*A Treatise on Insanity*, London, 1835) introduced the term "moral insanity" as designating "madness consisting in a morbid perversion of the . . . affections . . . moral dispositions and natural impulses without any remarkable disorder or defect in the intellect or knowing and reasoning faculties and particularly without any insane illusion or hallucination." The McNaghten rules have been rightly criticized in that "they . . . responsibility with knowing and reasoning, whereas any sane man with experience of the insane must know of many persons as to whose insanity (and irresponsibility) there can be no possible doubt, who have realized the nature and quality of their act, have known that it was contrary to law, human and divine, and have shown remarkable cleverness in carrying out their object." (M.P.A., *loc. cit.*) In the United States, the "irresistible impulse" test was first introduced in 1884, and to-day it is used in seventeen States.

(3) The importance of ensuring that expert witnesses in such cases shall be suitably qualified psychiatrists cannot be exaggerated. It is true, however, that medical evidence at the present time is seriously distorted in having to fit in with obsolete legal conceptions of insanity. A jury is not competent

to understand the implications of specialized psychiatric evidence, as was abundantly clear when a juror asked who there was "anything in Heath's physical condition . . . would cause present disease of the brain," the assumption being presumably, that in the absence of organic disease there could be no "disease of the mind." There is much to be said in favour of establishing a panel of "medical practitioners, expert knowledge and experience of psychological medicine of recognized standing" whose competence and impartiality could not be questioned, and who would furnish a report to the accused in all appropriate cases to prosecution and defence before the trial (as advocated by B.M.A. and M.P.A.).

It is to be hoped that these matters, as also the question of indeterminate sentence, will receive full and careful consideration during any future discussion on the Criminal Justice Bill, and that this will result in more enlightened legislation similar to the Briggs Law in Massachusetts (1921), and the law on sexual offenders in Illinois (1938) and certain other States of the U.S.A.—I am, etc.,

Chelsea, S.W.3.

R. H. AHRENFELD

SIR,—Your correspondent (Oct. 26, p. 627) in reply to letter (Oct. 12, p. 555) states that the "essence of the pre-legal view is surely that a man is either responsible or irresponsible." No, Sir, not by any means. The essence of the pre-legal view is that in the case of conflicting medical evidence the jury (butchers, bakers, and candlestick makers) are asked to do the certifying—guided unerringly by the McNaghten Rules. Your correspondent also adds that "this has the merit of logic, justice, and simplicity." Simplicity is the word I am etc.,

Westcliff-on-Sea.

JOHN A. MCCLUSKIE

Work of Government Lymph Establishment

SIR,—I read with great interest the article on the work of the Government Lymph Establishment, published in the *British Medical Journal* of Oct. 26. I feel, however, that the Lieut.-Col. W. D. H. Stevenson, who was the Director of Government Lymph Establishment from 1929 until his death last year, would have wished to have added to it his oft-repeated appreciation of his entire staff for their co-operation during the war years, when they increased the output of lymph magnificently.—I am, etc.,

Stanmore, Middlesex.

J. AUDREY M. STEVENSON

Man in Relation to His Environment

SIR,—In the *Journal* of Sept. 28 (p. 471) it is reported that Sir P. Manson-Bahr (at the British-Swiss meeting) remarked "There were also geographical questions to be considered. How was it that heat stroke was much more common in the Liby area than anywhere else—for instance, in western Libya—where the conditions were much the same?" This question was answered by Air-Commodore Morton in his paper "Heat Effects in British Service Personnel in Iraq" (*Trans. roy. Soc. trop. Med. Hyg.*, 1944, 37, 347). Morton took a number of "salted men from the Western Desert for a trip round an Iraq desert just a few hours—allowing them to wear the headgear they had become habituated to in the Western Desert. They collapsed and had to take to "reactionary" forms of protection. The deserts of Mesopotamia are very much hotter than anything in Libya, in spite of the prestige attaching to the latter.

Prof. McCance, at the same meeting, remarked that " . . . the Tropics water was lost so quickly that the stimulus was never quite sufficient to enable the individual to drink himself back to normal. This had not been appreciated by those who had to live and work in the Tropics and handle men there." Prof. McCance's remarks do not apply to all who were responsible for the care of men in the Tropics—there are many enlightened individuals among the medical profession in hot countries. The trouble is that they cannot get their good ideas put into practice by the authorities responsible for policy. Dr. E. A. Carmichael stated: "The process of acclimatization or adjustment required from 4 to 7 days, by which time approximately 80% acclimatization had occurred."

I showed in 1935 (Marsh, F., *Trans. roy. Soc. trop. Med. Hyg.*, 29, 309) that acclimatization takes from 4-7 months for

climate like that of South-west Persia. In spite of differences of opinion it is good to see that the subject of effects of heat is now again a "live" problem and lifted out of the "forgotten" zone, like the army that suffered from both effects of heat and of forgetfulness.—I am, etc.,

Eppings.

FRANK MARSH.

Pyloric Stenosis in a Child

SIR,—The following case of pyloric stenosis in a child after swallowing corrosive poison appeared to be interesting enough to report.

A boy aged 2½ was brought to the Royal Gwent Hospital, Newport, in March with a history of having swallowed some acid which was being used to put in a battery. The child was detained in hospital for three days and was discharged as apparently there were no symptoms. I first saw him four weeks later when he was readmitted to hospital suffering from vomiting and abdominal pain, also loss of weight. X-ray examination showed marked pyloric stenosis with delayed emptying of the stomach—three-quarters of the meal being still retained at the 5-hour examination. There was no other abnormality apparent. At operation the pylorus was seen to be thickened and stenosed, giving the appearance which one usually associates with a chronic ulcer. Posterior gastrojejunostomy was performed. The stoma admitted three fingers. The child was discharged from hospital in three weeks having made an uneventful recovery.

Subsequent x ray shows the gastrojejunostomy to be functioning normally, with nothing passing through the pylorus. The child has regained its lost weight and is eating normally.—I am, etc.,

Newport, Mon.

J. T. RICE EDWARDS.

Parasyphilis

SIR,—I rubbed my eyes to read in your issues of Aug. 31 (p. 311) and Oct. 5 (p. 514) the word "parasyphilis" applied apparently to meningo-vascular syphilis, general paralysis of the insane, and tabes dorsalis. Parasyphilis one believed was an outdated term referring to the above syphilitic conditions used at a time when their true nature was still unproven. This assignation was generally understood to refer to certain diseases of the nervous system, including general paralysis and locomotor ataxia, which were formerly considered to be due indirectly to syphilis but are now known to be directly dependent upon syphilitic lesions in the organs concerned. The parasyphilitic doctrine, in general paralysis at any rate, was abandoned with the discovery of the living spirochaete in the brain tissue of general paralytics by Noguchi and Moore in 1913.¹ One wonders if the fact that general paralysis is the only form of nervous syphilis in which the spirochaete is found in the parenchymatous tissues of the C.N.S. has led to the persistence of the belief that other forms of nervous syphilis are still only indirectly due to syphilitic infection. I would like to hear the views of those who still use what I believed was an entirely outdated term.—I am, etc.,

London, N.6.

W. LEES TEMPLETON.

"Analgesic" or "Anaesthetic"?

SIR,—It seems appropriate at the present time to register a protest against the attempt to substitute the ugly term "analgesic" for "anaesthetic" when speaking of drugs which do not cause loss of consciousness. While it is obvious that a distinction exists, it is only one of degree; the term "analgesic" implies the loss of pain sensation only, and "anaesthetic" the loss of all sensation: surely then "anaesthetic" remains the best word for drugs such as novocain which are capable of abolishing all sensation locally or regionally? It is well known that they abolish taste sensation, and if they do not normally affect sight, hearing, or consciousness, it is only because they do not normally come into contact with the optic and auditory nerves or with the higher centres. The only legitimate criticism that can be levelled at the term is that it does not imply the added abolition of efferent nerve impulses,

which is a characteristic of all "anaesthetic" drugs, most of all of the so-called "analgesics"; and this does not seem to be a justification for the adoption of an even less comprehensive term. In my view the word "analgesia" is justly applicable only, for the want of a better, to intravenous general "analgesia," and, crowning absurdity of all, to the first stage of general "anaesthesia." It is gratifying to note that the writer of your leader (Oct. 12) did not find it necessary to use this jargon.—I am, etc.,

Colchester.

J. N. FELL.

Pronunciation of Medical Words

SIR,—With regard to Dr. Margaret Vivian's inquiry (Oct. 5, p. 516) concerning the pronunciation of E. Bleuler's term "schizophrenia" there appears to be fairly general agreement that "skizo-" is the correct sound (see, for example, Gould's *Medical Dictionary* and Dorland's *American Illustrated Medical Dictionary*). This is also the form given in the *Oxford English Dictionary* for words beginning with "schizo-" (from *σχίζω*, to divide), but there the "i" is stated to be pronounced as in "bind"; this lengthening of the Greek short "i" is seen in "psychiatry" ("paediatrics," however, is usually pronounced *pe-de-at-riks*). Fowler (*A Dictionary of Modern English Usage*) remarks: "The oddities of English treatment of Greek words are well illustrated by *schism* (sī-), *schist* (shī-), and *schizomycete* (skī-), all three being from the same Greek word." No doubt arises about the second part of "schizophrenia," which is derived from *φρέν*, meaning mind here, or diaphragm in other contexts.

A more difficult problem is presented by the much older word "syndrome." While medical dictionaries (e.g., those of Gould and Dorland) favour a silent "e" (cf. aerodrome, hippodrome), more general works (e.g., the *Oxford Dictionary*) require its pronunciation, thus following the Greek *σύνδρομη*, meaning a concurrence. It is interesting to note, however, that occasionally in the seventeenth century the word was written "syndrom" in English.—I am, etc.,

Cork.

R. O'RAHILLY.

SIR,—In the gay letter of Dr. C. E. S. Harris and in your footnote to it baffling problems of pronunciation are raised. The hard or soft C is a perennial headache. The K of the Greeks so often through Latin and the Romance tongues has become the S of many of our words. But not all, is the trouble. "The flicks," perhaps due to the immense American concern with them, are always spoken of as the sinema, but who heard of caput pronounced as saput? Unhappily an intermediate position exists with the cephalic words. Here, I think, the C is always hard, while in America it is usually soft. A living language is bound to change, properly and inevitably. One of the few things I remember of my school days is that an apron etymologically is a napron. But everybody calls an apron an apron. The change is complete.

Webster and Wyld follow the *Shorter Oxford Dictionary* in giving encephalitis a soft C, but it may be that the copying with which we are not unfamiliar in medical textbooks operates here—though who copied from whom I have no idea. I think, as you, Sir, that most medical men here give it a hard C, while in America I think a soft C is the rule. This lack of uniformity can be puzzling, for although it does not matter which is adopted it is a pity that these differences occur. Should we change? Well, unlike most of the rest of the world we persist in keeping to the left of the road, and simple utilitarianism is a poor motive. There are other factors, and I believe we should stick to the hard C as much as possible.—I am, etc.,

London, S.W.1.

E. GALLOP.

The Wellington correspondent of the *Times* reports that New Zealand has signed an agreement on behalf of Western Samoa and the Cook Islands with the Government of Fiji and the Western Pacific High Commission for the inauguration of a joint health service in the Southern Pacific. New Zealand and Fiji have for twenty years shared certain health services, but the new agreement will establish a joint board of administration with an inspector-general, and will provide for central medical and nursing schools and for greater co-operation. Dr. J. C. R. Buchanan, of the Colonial Medical Service, has been appointed the first inspector-general.

Obituary

SIR LOUIS BARNETT, C.M.G., F.R.C.S.
F.R.A.C.S., Hon.F.A.C.S.

We regret to announce the death at Dunedin of Sir Louis Barnett, emeritus professor of surgery in the University of Otago and a past president of the New Zealand Branch of the British Medical Association. He presided over the Australasian Medical Congress in 1927 and was president of the Royal Australasian College of Surgeons for two years; he was also an honorary Fellow of the American College of Surgeons. His long service in the chair of surgery did much to establish the reputation of the Otago Medical School on the firm foundation on which it now stands.

Louis Edward Barnett, son of Alfred A. Barnett, J.P., was born on March 24, 1865, at Wellington, N.Z. He was educated at the Wellington State School and College and at Otago University, and then came to this country, graduating M.B., C.M. of Edinburgh University in 1888 and taking the F.R.C.S.Eng. in 1890 after a year in London as house-surgeon at the Middlesex Hospital. Returning to New Zealand, he was elected in 1895 to the honorary staff of the Dunedin Hospital, which he served as surgeon for thirty years, and during the same period was lecturer and then professor of surgery in the University of Otago. He was given the title of emeritus professor in 1925. During the war of 1914-18 he served with the N.Z. Expeditionary Force and was appointed consulting surgeon with the rank of lieutenant-colonel. He received the C.M.G. for his war work and was knighted in 1927.

Sir Louis Barnett had joined the B.M.A. in 1889 and came to London to hold office as vice-president of the Section of Surgery at the Centenary Meeting in 1932. He pioneered the foundation of the Dunedin Radium Institute, and in fighting cancer he probably did more than any other New Zealander to awaken public realization of the need for the encouragement of research. It was to this cause that he devoted a large part of his energies after his retirement from active professional work. He was vice-president of the N.Z. Cancer Campaign and chairman of the Hydatid Research Committee in the Dominion. He had also been chairman of the Otago and Southland Division of the British Empire Cancer Campaign.

STUART McDONALD, JUN., M.D., Ph.D.

The sudden and untimely death in Edinburgh of Stuart McDonald, jun., on Oct. 23 is a great loss to Scottish medicine. Scarcely more than a year ago, on returning from war service, he had been inducted into the chair of pathology at the University of St. Andrews and took up the associated post of pathologist to Dundee Royal Infirmary. His gift for teaching, research, and administration was widely recognized.

Stuart McDonald, a son of Emeritus Prof. Stuart McDonald, M.D., who held the chair of pathology in the University of Durham, was born forty years ago. He was educated at Fettes College, Edinburgh, and at Gonville and Caius, Cambridge, where he graduated B.A. in 1926, M.A., M.B., B.Ch. in 1930, and M.D. in 1938. He early showed a leaning towards his father's branch of medical science and became demonstrator of pathology in the University of Durham College of Medicine at Newcastle and assistant pathologist to the Royal Victoria

Infirmary. He was then senior lecturer in pathology in the University of Birmingham, which later gave him the degree of D.Sc. and senior assistant pathologist to the Birmingham General Hospital. He was commissioned as captain, M.C. (T.A.), in May, 1939, and entrusted with the organization of emergency hospital services in a threatened southern area. After service in France he left for the East to take up the post of assistant director of pathology (research) at General Headquarters, India Command, with the temporary rank of lieutenant-col. This work called for unceasing exertion under tropical conditions, which undermined his health.

In March, 1945, it was announced that the Court of the University of St. Andrews had appointed Stuart McDonald to the chair of pathology and the Directors of the Dundee Royal Infirmary to the post of pathologist and clinical pathologist, and soon afterwards he became regional director of the Blood

Transfusion Service for East Scotland. He was a member of the Pathological Society of Great Britain and Ireland and the Medical Society for the Study of Venereal Diseases. His published writings include papers in the *Journal of Pathology and Bacteriology*, in the *Indian Journal of Medical Research*, and in the *British Journal of Venereal Diseases*.

The Principal of the University of St. Andrews, Sir J. Irvine, has paid public tribute to Stuart McDonald's brilliance as a teacher and investigator, whose services to medical education were of the utmost value, and has written of the well given by his colleagues and students at St. Andrews who was recalled to Scotland in 1945. "Stuart McDonald was a man richly endowed with ability, with the constructive imagination which lies at the basis of all scientific work, and with personal charm which endeared him to those who worked with him. The sympathy of all who knew him goes out to his widow and young children and also to his distinguished friends in whose footsteps he followed and to whom he owed so much."

Prof. H. F. Humphreys writes from the Medical School Hospitals Centre, Birmingham:

May I pay a tribute from the many medical officers who served with him in the 1939-45 war to the memory of Stuart McDonald. He was his commanding officer in the 14th General Hospital from early months of 1939, when he helped me to raise it as a Territorial unit, to the autumn of 1943, when his reputation as a pathologist brought about his transfer first to the Central Military Laboratory, Poona, and a year later to G.H.Q. India as Director of Research. It is, however, of his personal qualities that I wish to write rather than of the professional eminence that brought about his selection for the chair of pathology at St. Andrews. He was mess president for more than half his time with the unit, not an easy task for thirty or more medical officers of widely varying personality crowded together in trying conditions of climate and quarters; he discharged it to admiration. His capacity for exact business, his tact, his personal charm and his marked social gifts made him a unit favourite, and did much to provide that happy mess background which adds so much to the efficiency of a hospital. McDonald was a Highlander, with that heightened capacity for exaltations and agonies which distinguish the Highlander from the more prosaic Scot. The former were evident during a memorable 80-mile tramp I took with him in the high Himalayas during the monsoon of 1942, and later were revealed in his sharp antipathy to India and during his last illness. The sympathies of his brother officers go out to his family and to the University of St. Andrews.

ERNEST MALLAM, M.D.

We have to report with regret the death of Dr. Ernest Mallam, who died suddenly at Oxford on Oct. 24 after an illness of six weeks.

The son of Dr. Henry Parr Mallam, a well-known Oxford practitioner, Ernest Mallam was educated at Magdalen College, Oxford, and subsequently at the London Hospital. He took his M.A. in natural science, gaining first-class honours, and his M.B., B.Ch. in 1895, and his M.D. in 1904. At the London Hospital among other posts he held that of a house-physician and returning to Oxford he was appointed house-physician to the Radcliffe Infirmary. His abilities as a physician soon marked their mark and in 1900 he was appointed honorary assistant physician to the Radcliffe Infirmary. He did not have to wait very long for advancement, and in 1904 was elected a physician to the hospital, a position which he held until 1915 when on retirement he was appointed a consulting physician. Always interested in diseases of the skin, he was instrumental in the formation of a department of dermatology of which for many years he was the physician-in-charge. Although a busy and much-sought-after general practitioner he gave up much of his time during the 40 years he was on the staff to the service of the hospital. A man of sound judgment, and one with wide clinical experience, his opinion was highly valued both in general practice and as a consultant; and in committee work, over a long period of years, he played a big and active part in the management and development of the Radcliffe Infirmary. For many years he was secretary of the Honorary Staff Committee, secretary and president of the Oxford Medical Society, a member of the Dermatological Section of the Royal Society of Medicine, and President of the British Association of Dermatologists and Syphilologists. He had also been chairman of the Oxford Division of the British Medical Association and president of the Berks, Bucks, and Oxford Branch.

Ernest Mallam was a good friend to all and a genial host, man who gave his life to the service of his hospital and of its patients, who were in all classes of the community. He belonged to the fast diminishing brigade—the practitioner—men whose wide experience of general practice as brought to the bedside of their hospital patients, and whose work as physicians in a hospital kept them in touch with modern medical thought and practice. In this way they acquired qualities of a high order, and those qualities were possessed by Ernest Mallam to the full. His son, Dr. Patrick Mallam, the third generation which the Mallam family have given to Oxford medicine, is now a physician on the staff of the Radcliffe Infirmary. E. C. B.

Dr. ALEXANDER WYLIE EADIE, who died on Sept. 11 in the Hartley Hospital, Colne, was educated at Glasgow High School and graduated M.B., Ch.B. at Glasgow University in 1907. He held house appointments in Dundee Royal Infirmary, Victoria Infirmary, Glasgow, Monsall Fever Hospital, and Burnley Infirmary. In 1914 he settled in practice in Colne. Eadie soon proved himself a fine type of family doctor. An astute clinician and observer, well versed in modern practice, he rejected with disdain what he considered mere popular fashion. His death, at the age of 61, may be attributed largely to his devotion to his patients, whose confidence he held not only through his professional skill but also through friendly talks on matters relating to education, conduct, and career. As a member of the honorary staff of the Hartley Hospital since its opening in 1924, he contributed in no small degree to its reputation, which extends far beyond the borough boundary. Apart from his practice, and the problems of humanity, his main interests were in architecture, etchings, and antique furniture, on all of which he was an authority. He leaves a widow, three daughters, and a son, Squad-Ldr. J. G. Eadie; their grief at his loss is shared by all with whom he came into contact. A crowded funeral service testified to the great respect in which he was held throughout the district.—F. C. M.

The death, at the age of 55, of Dr. ANDREW ROYSTON ELLIOTT occurred at his home in Tunbridge Wells on Oct. 2. He was educated at Dulwich College, after which he graduated M.B., B.S. (Lond.) from the London Hospital in 1913. Several house appointments there were interrupted by his joining a very early Red Cross contingent sent to Belgium in 1914, during which he was captured and narrowly escaped death as a suspected spy before eventual release and return to England. In 1916 he joined the R.A.M.C. as a temporary officer and served in France and Mesopotamia before demobilization and his taking of the London M.D. in 1920. After six months as R.S.O. at the West London Hospital he joined in partnership in old hospital colleague and friend at Crowborough. He joined the B.M.A. soon after qualification. At Crowborough he remained, a bachelor, in active practice until within a year of his untimely death. Recognition in a widening circle of his sound qualities as a physician led in 1938 to his appointment in that role to the staff of the Kent and Sussex Hospital, Tunbridge Wells. It was entirely characteristic of the man that, having developed over the years an almost abnormal sense of duty, he gave more and more time to his hospital and consulting work, without in the least trying to ease up in his Crowborough practice. That this hastened in some measure his death there can be little doubt. Elliott was in his day a brilliant lawn tennis player and a sound golfer. He could do anything with his hands—surgery, midwifery, carpentry, or brick-laying.—A. E. W.

Dr. SYDNEY ARTHUR OWEN, who died in London on Oct. 14, was essentially a paediatrician, though he was also a general physician and during the late war did valuable administrative work as deputy hospital officer for Sector VII of the Emergency Medical Service. At Trinity College, Cambridge, he won an exhibition and was placed in the first class of Part I of the Natural Sciences Tripos. He went on to University College Hospital, where he won the Atchison scholarship and senior Fellowship medal, graduating M.B., B.Ch. in 1905. He took the M.D. and M.R.C.P. five years later and was elected F.R.C.P. in 1928. Sydney Owen's earliest appointments were those of resident medical officer at U.C.H. and at the East London Hospital for Children, Shadwell, and in middle life he served on the visiting staff of the City of London Hospital for Chest Diseases, Victoria Park. For many years he was physician to the Queen's Hospital for Children at Hackney and physician to the infant welfare department of the City of London Maternity Hospital. He had been consulting paediatrician to the L.C.C. and was in charge of the children's department of the West London Hospital for fifteen years. He was also physician to

the Princess Louise Kensington Hospital for Children from the time of its reconstruction, and consulting paediatrician to the Royal Hospital, Richmond, and the British Hospital for Mothers at Woolwich.

Dr. SIDNEY DEANER, chief tuberculosis officer for Worcestershire and Secretary of the Worcester and Bromsgrove Division of the B.M.A., died on Oct. 15 at the early age of forty-two, leaving a widow and young son. After qualification from St. Mary's Hospital he followed his clinical interest in Ealing, South Wales, Papworth, and Sheffield, and spent most of his too short life assisting the tuberculous in Worcestershire, succeeding to the post of Chief County Tuberculosis Officer in 1939. He was enthusiastic and industrious: the organization of a specialist chest surgery unit at the county sanatorium, his manifold Civil Defence duties, service in the cause of the Midland Tuberculosis Group of the Society of Medical Officers of Health and of the B.M.A., his original description of silicosis in a local industry, and his courageous attempt, while bedridden, to become proficient in the medical vocabulary of the Russian language—may be instanced. His happy relations with that wide circle of doctors, patients, and the general public associated with his work will be long remembered in Worcestershire.

Dr. WILLIAM HENRY PEACOCK, formerly of the West African Medical Service, who had lived recently in Shropshire at Church Stretton, died at the East Suffolk and Ipswich Hospital on Oct. 22. He was born on Feb. 2, 1881, and from Darlington Grammar School went to the University of Durham College of Medicine, Newcastle-upon-Tyne, graduating M.B., B.S. in 1903, and taking the Cambridge D.P.H. with distinction in 1914 and the D.T.M.&H. of the English Conjoint Board in 1922. He had a distinguished student career at Newcastle, winning two scholarships before qualification, and was then for a time casualty officer at the West London Hospital. He joined the West African Medical Staff in Southern Nigeria in 1910, and during the war of 1914–18 held a temporary commission in the R.A.M.C. He saw active service in the Cameroons and with the British Salonika Force, was mentioned twice in dispatches, and received the Order of St. Sava, 5th class. On demobilization in 1919 he was appointed senior sanitary officer for Sierra Leone, and deputy director of the Sanitary Service seven years later. He was transferred to Nigeria in 1930 as deputy director of Health Services and retired in 1935, soon after receiving the C.B.E. Dr. Peacock joined the B.M.A. in 1907 and represented his Division at the Annual Meeting at Edinburgh in 1927.

E. A. U. writes: In your issue of Oct. 12 you published a very full and sympathetic account of the career of Sir WALTER LANGDON-BROWN, and to that I should like to add a note on his great interest in the history of medicine. The obituary notice mentioned the wide range of his studies and his aptness in using the telling phrase. It was inevitable that Langdon-Brown should ultimately give serious attention to historical studies, and the latter part of his career displayed him as a master in what was to him a relatively new field. I know of at least fifteen historical articles written by him during the last seven years. In 1939 he delivered the Thomas Vicary Lecture, choosing as his subject "The Apposable Thumb." In his Inaugural Lecture at Cambridge in 1932 he spoke on "English Medicine and the Cambridge School," and in this he foreshadowed his later interests. During the four years when he occupied the presidential chair of the History of Medicine Section of the Royal Society of Medicine, he gave papers on the history of the Cambridge School which were intended to form a small book on that subject. His final essay on "Clifford Allbutt and the Transition from the Nineteenth Century" had to be postponed because of the surgical operation which marked the commencement of his long illness. It was a great disappointment to him that he was never able to read that paper: it was finally read for him by the present occupant of the Regius Chair of Physics at Cambridge. These papers were published in book form a very short time before his death with the title *Some Chapters in Cambridge Medical History*. This little work is full of ripe wisdom, and it shows on every page the author's knowledge of his subject and his great love for his Alma Mater. Langdon-Brown served as President of the History Section of the Royal Society of Medicine from October, 1939, to October, 1941, and again from October, 1942, to October, 1944. His occupancy of the presidential chair was marked by a quiet dignity, and by the unobtrusive display of a wealth of learning which seemed to embrace all subjects with equal ease. He was a big man, physically and mentally, and those whom he honoured with his friendship were indeed fortunate. One of his favourite quotations was the remark of Dr. Johnson that "Dr. Mead lived more in the sunshine of life than almost any man," and the same phrase might well be applied to Langdon-Brown himself.

Medical Notes in Parliament

HEALTH SERVICE BILL

THIRD READING

The LORD CHANCELLOR in the House of Lords on Oct. 31 moved the Third Reading of the National Health Service Bill. Lord Jowitt said that the Government had not been able to make the amendment which Lord Cecil of Chelwood had asked it to make to deal with deafness. To-day a vast amount of unhappiness was caused by deafness which could at least be alleviated by modern methods. But having used all his ingenuity he could not see how he could put anything in the Bill about it. This matter of the ear was not like the matter of the eye. Ophthalmic opticians could tell what spectacles ought to be used, but if he had anything the matter with his ear he would intensely dislike going to someone who was not a qualified doctor. It was wrong that an intricate mechanism should be at the mercy of people not qualified to deal with it. If ears could not come into the Bill as a supplementary service they could come as part of the general hospital service under Clause 3. If deafness were specified in that clause then Lord Horder would want to put in rheumatism, and Lord Moran tuberculosis, and therefore, after consulting Mr. Bevan, the best he could do was to repeat the definite assurance that a comprehensive service must include provision for deafness. To-day people were concerned to sell for the highest price instruments which had little effect on deafness, and the nation was reluctant to bring other instruments from America and so to use its precious dollars. He gave the House an assurance that he would take up that matter with Sir Stafford Cripps. The Government would do all it could at the earliest time to produce in as large numbers as possible the best scientific instruments and to make them available to the public free of charge.

The Lord Chancellor went on to say that he was grateful to the House for the constructive way in which it had discussed the Bill. By allowing him to meet as far as he could the wishes of the House Mr. Bevan had shown good sense and good judgment. Some of the alterations accepted wrote into the Bill an undertaking which Mr. Bevan had given verbally. An illustration of that was the case of the denominational hospitals. So far as endowments were concerned the Government had hit upon a method which met the general wishes of the House. It did not interfere with the broad general principle that endowments were to be devoted generally to all hospitals, but it did protect specific endowments intended for particular purposes.

It was a good thing that the powers of hospital management committees had been set out as they were in the Bill. The best people need not hesitate to come in for fear they would be ciphers without real work to do. In regard to the discovery of documents in the event of litigation the Government had made plain what it intended. One alteration of real substance had been made. It affected the time between the appointed day and the passing of the Act—which might be as long as eighteen months. The Minister had arranged that after the appointed day endowments given to a particular hospital should not be taken away from it. The House had extended that principle to the time directly after the Bill became an Act of Parliament.

Salaries and Certificates

He thought the Peers were wrong in saying that no part of a doctor's remuneration should be by way of salary. The success of the scheme depended in large measure on getting satisfactory certification. With lax, or still more with dishonest, certification all the schemes were going to break down. He had a profound regard for the medical profession and its standard of honour, but when Minister of National Insurance he had come across cases—not many—where there were two competing doctors, one of whom was strict with his certificates while the other was lax. The people on the panel of the strict doctor were inclined to go to the panel of the lax doctor because they could more easily get certificates. That temptation would have gone if the per capita payment had been abolished and a straight salary substituted, but the change would not have been practical politics. Giving something in the way of salary would have been a very valuable thing.

The other blemish in the Bill as amended was in the special treatment of London. It was a great pity that health services should be split between borough councils and county councils. The amendment carried by Lord Balfour of Burleigh did not seek to transfer all the new powers to the borough council, only the powers they already had with perhaps some slight extension. For the rest the Bill preserved the absolute right of choice of

doctor, and he hoped the public would realize this. If Government were not going to move people about. If nurses had a contract to serve in a particular place they could only be called upon to serve in that place. Under the Bill there would always be a great need for well-disposed persons to help the money and by service, and he hoped that the passage of the Bill would not prevent voluntary service from being forthcoming. He moved the Third Reading.

"Acting in an Honorary Capacity"

Lord LLEWELIN said the amendments put forward by the Opposition in that House were not put forward with a view to ruining the Bill or to making it ineffective. Good improvements had been made in the Bill. The House had made certain that a doctor, whether acting in an honorary capacity or not, who served on the staff of one hospital could get his patient admitted, or might even treat him, in another hospital. That was important, because in a lot of small hospitals there was no resident staff. He hoped the Bill would not result in the closing down of smaller hospitals in country towns which attended to minor ailments not in need of special treatment in larger regional hospitals. He was grateful to the Government for drafting a satisfactory amendment dealing with endowments given for a special purpose. The insertion of the words "control and manage" in regard to hospital management committees seemed to have met the desire of the House that the Committees should be given a better function. He was also satisfied with the words accepted by the Government about the disclosure and production of documents.

He was obliged for the assurance that the doctors would be given adequate time before the appointed day to know what their conditions were and also for the assurance that dentists would be allowed to have their names on two lists. The provision about partnerships was also of use, and the measure had been greatly improved by providing that a doctor who might lose his livelihood through a decision of the Tribunal or of the person appointed by the Minister to hear the appeal should be entitled to be represented by counsel or by a solicitor, to call evidence, and to produce documents. He thanked the Minister for the provision in regard to hospitals connected with some religious denomination. The House had rightly restricted the power of the Minister to alter, of his own volition, the Acts or Regulations under it. He noted that the Lord Chancellor had not described as a blemish on the Bill the amendment which made management committees capable of suing and of being sued. He hoped that amendment would stand part of the Bill.

Proportion between Salary and Capitation Fee

On the question of a salary or capitation fee Lord Llewellyn remarked that the House had never been told what in the normal case was to be the proportion between the two. If it was to be 25% salary in the normal case and 75% capitation there would not be much between the Opposition and the Government. If the Government would state what proportion they had in mind for the normal case that would put a lot of anxieties to rest. The Lord Chancellor had said the capitation fee would mean doctors' perhaps getting more patients because these doctors were lax in the way they gave certificates. In these days the public had to have licences for everything, and a lady could not get a pair of corsets without a certificate from a doctor. In that event there would be a considerable temptation for her to change her doctor to one who would say that the garment was necessary for medical reasons. On the whole, however, the House did not want to take away from doctors the sense of energy and hard work, and part of that depended on their being able to attract patients by giving them good service. He noted that Lord Horder and Lord Moran had supported this amendment, and he remarked that the whole course of the debates on the Bill had shown how the House of Lords could act as a Council of State.

Lord READING remarked that although the specific scheme embodied in the Bill might be the production of the Government, yet the idea of a National Health Service had originated with the Government which embodied members of all parties. He believed that the Government should employ the eighteen months before the scheme came into operation in making plain to the people what the scheme included and did not include. The amount of ignorance prevalent in the country was incredible. Some educated people proclaimed that under the Bill no one would be entitled to go to the doctor of his choice and that with a temperature of 105° a patient would be forced under the Bill to go to a health centre and stand in a queue extending down the road.

L.C.C. and Metropolitan Boroughs

Lord BALFOUR OF BURLEIGH said that if the Minister accepted the amendment passed last week regarding the devolution of

the authority of the L.C.C. to the metropolitan boroughs it could be a tribute to the House. It was of fundamental importance to the people of London, for the local government of London was a thing entirely by itself. The Lord Chancellor dubbed the proposal as "retrograde," but in that he (Lord Alford) disagreed. He wanted the same thing as the Lord Chancellor, that the children should get their treatment in the home centre. If the administration was handed over to the London County Council those intimate services would be administered from County Hall. At present if a mother had complaint to make or desired an opinion or had a suggestion to make she had only to seek out one of the local councillors to go to the town hall and see the medical officer of health. The services were transferred to the County Council the personal touch would be lost.

There was the far bigger question of the maintenance of a two-tier system of local government in London. How could the quality of the borough councils be maintained if the important health service, which attracted so many members, was to be removed? L.C.C. administration was bureaucratic. It was a fact that in one, and perhaps other, L.C.C. hospitals neither a medical superintendent nor the matron could condemn a midwife without reference to County Hall. The indication was clear that the Coalition Government, whatever scheme they might have decided to set up throughout the country, would have left the maternity and child welfare services with the borough councils. No change of circumstances had been introduced to justify the change in plan. It was profoundly to be hoped that the Government would have a good look at the Bill as it now stood.

Lord JESSEL said that the provision about London, which had always had separate treatment, was a very grave new departure, and would greatly discourage candidates, particularly women, for election to the borough councils.

The measure was then read a third time with its amendments and passed, and returned to the House of Commons.

FINAL STAGES

The Lords amendments to the National Health Service Bill came before the House of Commons on Nov. 4.

Mr. KEY, Parliamentary Secretary, Ministry of Health, moved at the House should agree with the Lords amendment designed to secure that endowments to hospitals made before the Act comes into operation should, so far as possible, be devoted to the purpose for which they are intended by the donor and not placed in a common pool.

Mr. J. S. C. REID, speaking for the Opposition, said the amendment provided for the retention of gifts by hospitals subject to rather strict conditions, and it was important that the public should understand how stringent the conditions were. Big donors would be able to see that their money was used for the purpose intended, but small donors would see their money go into the common pool.

Mr. BEVAN, Minister of Health, said it was true that the amendment was intended to exclude from the endowment funds money that would ordinarily be paid for the general administration of the hospital. Unless there were safeguards of this kind ordinary weekly subscriptions could obviously be proscribed by simple form of words into a contribution to the endowment of a hospital, and he would find himself after a few months with an enormous deficit. These safeguards would prevent attempts to enrich the funds of a hospital at the expense of the Exchequer.

The Lords amendment was agreed to, and a similar amendment to cover the case of a war memorial embodied in a local hospital was also accepted.

On Clause 12 (functions of boards and management committees) Mr. KEY moved that the House agree with a Lords amendment that in any proceedings hospital authorities should not be entitled to plead privilege of the Crown regarding discovery of documents, but without prejudice to the right of the Crown to withhold documents whose disclosure would be contrary to the public interest. Mr. REID urged that the House ought to have a specific assurance from the Minister that he would use very sparingly the power to withhold discovery of documents. Mr. BEVAN agreed that this power ought to be used only in very exceptional circumstances.

The amendment was agreed to.

Health Services for London

On Clause 19 (local health authorities) Mr. KEY moved that the House disagree with a Lords amendment which provided that the London County Council should delegate to the Common Council of the City of London and the metropolitan borough councils the arrangements for the care of expectant and nursing mothers and children under five not attending

primary schools, the arrangements for home visiting, home nursing, and domestic help, and the arrangements for vaccination and immunization. He said that in the past there had been lack of real co-ordination in providing these home health services and now responsibility for them was to be concentrated in the county and county borough councils. He agreed that many of the London borough councils had provided good services in the past, but said the proposal that in this matter London should be made an exception to the rest of the country was quite unacceptable to the Government. The set-up envisaged in the amendment would lead to greater possibilities of administrative friction and mean a loss of efficiency. The Bill gave a service of common standard in all areas of London irrespective of their poverty or wealth. Under the amendment, which provided that 50% of the cost was to be borne by the boroughs, really unbearable burdens would be placed on poorer areas and the people there would have to put up with less efficient services. The unification under the Bill did not mean that there could not be real co-operation between the L.C.C. and the borough councils and did not exclude the possibility of the local knowledge of borough councillors being used. Power had been given to the L.C.C. and the borough councils to co-operate in the subcommittees which would be necessary for carrying out the services in the various areas—for representatives of the borough councils to share with the county council in management and control. There was still in existence a provision of the London Government Act, 1939, which enabled the borough councils and L.C.C. to get together and put forward schemes to the Minister relating to services which they wanted to share or to powers which they wished to delegate one from another.

Mr. RICHARD LAW recalled that in 1944 the Metropolitan Boroughs Joint Standing Committee, under the chairmanship of Mr. Key, came to an agreement with the L.C.C. It was clear when the Coalition Government White Paper was published there would have to be some division of responsibility as between the L.C.C. and the metropolitan boroughs, and without any pressure from the then Minister of Health, but with his good will, the two bodies got together and reached agreement. The tenor of that agreement was that maternity and child welfare work should be delegated by the L.C.C. to the borough councils, which was what—generally speaking—was proposed by the amendment. Mr. Key, as chairman of the Metropolitan Boards Standing Joint Committee, used great influence and persuasion in order to bring about a division of powers such as was embodied in the amendment which he was now rejecting. He did not want to go into the reasons for the *volte face*.

Mr. KEY, intervening, asked if it were possible for Mr. LAW to understand that a person could serve a team, even though a second team which he joined had a different attitude from the first. When he spoke as chairman of the Metropolitan Borough Councils Subcommittee he was bound to voice their opinions, irrespective of whether they were his own. That was the essence of democracy.

Mr. LAW said he did not follow Mr. Key's new definition of the team spirit and democracy. Anyone who changed his mind because he changed his job was, in fact, doing a great disservice to democracy. The L.C.C. and the metropolitan boroughs must have agreed that the services which it was proposed in the amendment to delegate were essentially personal services, much better handled by the relatively small metropolitan boroughs than by the L.C.C., which had the care of between 3,000,000 and 4,000,000 of the citizens of London. The services had been discharged very well by the boroughs for many years, and another argument considered must have been that removal of the services from the purview of the metropolitan boroughs would result in very great weakening of local government in London.

Too Many Authorities

Mr. SOMERVILLE HASTINGS said that under the amendment London alone would have four authorities instead of three. He had been a member of the hospital and medical services committee of the L.C.C. for about fifteen years, and he had seen the difficulties that arose where functions were divided between two authorities, as in the case of tuberculosis. There were already quite enough authorities under the Bill without increasing them further. One of the objects of the Bill was to associate the doctors as closely as possible with the preventive services at the health centres. The amendment would separate much more than was necessary the preventive and curative side of the treatment of disease.

Mr. HOWARD said that Mr. Key had not put forward a single argument to show that the individual nursing mother or child would get better service if the amendment was rejected. It was something of a red herring to suggest that because powers

of consultation were contained in the Bill, it was ridiculous to want any powers of delegation.

Mr. GOODRICH said he did not think the fear of non-contact between patients and representatives was justified. He was convinced now, though not formerly, that it would be better for these services to be administered by the L.C.C. Mr. MARLOWE said the Parliamentary Secretary had made out a strong case administratively, but there were other issues. The whole purpose of the Bill was to do good for the individual, and the L.C.C. was too vast for contact to be maintained between the authorities and their patients. Mr. SPARKS said he believed that by centralizing responsibility the standard of these services would be improved. They in Middlesex regretted the loss of half their services, but they were not going to adopt a "dog in the manger" attitude which would prevent other counties getting better standards.

Mr. H. STRAUSS (English Universities) said that from his experience the people living within the area of the London County Council were overwhelmingly in favour of these services remaining under the control of the metropolitan boroughs. The people of London had a more intimate regard for their own town hall than they had for the county hall. From the point of view of efficiency, too, there was no reason to suppose that the L.C.C., which had never exercised these functions before, would exercise them now more effectively than the metropolitan borough councils, with all their experience of these services, had done in the past. Mr. E. FLETCHER said that the L.C.C., of which he was a member, had expressed its views on the issue. Everyone sympathized with the metropolitan boroughs in losing the maternity and child welfare services which they had built up with such success; but not all had reached the same standard of efficiency.

Mr. BEVAN said the agreement between the L.C.C. and the metropolitan boroughs had nothing to do with the issue, because the scheme in the Bill was radically different from the one his predecessor in office had placed before the boroughs. The devisers of the scheme in the amendment, because of the nature of local government in London, found themselves faced with exactly the same anomaly as he was faced with in the whole country. Whenever difficulties arose they arose out of the fact that in selecting a particular category of local authorities one was bound to find anomalies. In considering the question of accessibility members of the Opposition had forgotten the health centre. He believed that local authorities ought to be able to be approached by the citizen, but if a citizen in future was in difficulty about his health he would go to the health centre and not to the town hall.

The motion to disagree with the Lords amendment was carried by 296 votes to 134—Government majority 162.

Payment of Doctors

On Clause 33 (arrangements for general medical services) Mr. BEVAN moved that the House disagree with the Lords amendment which laid it down that the remuneration of doctors providing general medical service should be by the capitation method, save in exceptional cases. There was no such restriction in the National Health Insurance Acts, he said, and he did not want the Government to be placed in a strait waistcoat when fixing doctors' remuneration. It was not desirable that future negotiations with the medical profession about remuneration should start with a statutory inhibition, and that some agreed basis could not be adopted without resorting to fresh legislation. Supporters of the Government had always felt that the young doctor starting in practice should have a certain degree of security, and it was the Government's intention that he should start with a salary. A doctor did not examine his patients better because his heart was gnawed by financial anxiety. A basic salary was justified on that ground alone, but it would also reduce to some extent the competition for patients. Panel lists had not always been built up by methods which commended themselves to the best elements in the profession. The size of the panel list did not always indicate the merits of the doctor; some had better advertising methods than others. A basic element in the remuneration made it easier, also, to award additional pay for special attainments.

Some doctors had expressed the fear that this was the beginning of an attempt to introduce full-time medical service. He could not see into the mind of any future minister or prophesy what might be done by a future Government, but that was not the intention of the present Government. Their intention was that the main source of the doctor's remuneration should be by capitation payments. There was an argument for having a full-time salaried service or for having remuneration wholly on a capitation basis, but none for having a high basic salary and a small capitation payment. It would be difficult to carry out the recommendations of the Spens Report

if the basic element were too high because then the cap rate would have to be lower and the highest remuneration could not be achieved without far longer panel lists than could agree to.

Mr. J. S. C. REID said one of the main objections—some people's view the main objection—to the Bill was a tendency to undermine the independence of the medical profession. If there were any truth in that charge the amendment was a crucial one. At present a doctor depended entirely on winning and keeping the confidence of his patients; he was their servant, and the servant of no one else, and the Government neither harmed nor benefited him in any way. As there was introduced an element of salary there was an inevitable tendency to produce Government control, and arose a divided loyalty on the part of the doctor. The object of the basic salary in the Labour Party's policy was to get control of the individual doctor. The Bill contained a limitation of the proportion of remuneration to be paid, and if the amendment were rejected the Government would have a free hand to make alterations bringing the situation nearer to their official policy. If a doctor received a substantial salary and had only a small number of patients it would be necessary for the Minister to direct a number of unwilling patients to him. At present the great majority of doctors were free and independent, but as soon as they were paid on a salary basis the existing atmosphere of freedom and independence would change fairly rapidly for the worse, and this in turn would result in a serious diminution in the quality of the service which they rendered. It was not in the interests of the doctors, nor was it their wish, that the conditions should change in the way the Government proposed.

Sir H. LUCAS-TOOTH said that if it was agreed that a salary was desirable for doctors the same argument might be accepted for every other profession which served the public. Mr. GAGE said that if there was a salaried service there would be a falling off in public confidence in doctors and in the standard of the profession.

Varying Medical Views

Sir H. MORRIS-JONES said the majority of the medical profession preferred the capitation system. A salaried system would take the glamour out of the profession and replace it with a uniformity in which there was no personal contact between patient and doctor.

Dr. MORGAN said they had been treated to a whole series of jeremiads that if a doctor was paid a salary his services would not be so good because of that fact. He would only refer to the salaried doctors of the Indian Medical Service, the Colonies, medical officers of health, the laboratories—were the bad doctors because they were paid by salary? Mr. MARSHALL said that a salary was an inappropriate basis for the payment of professional men. The Minister was wrong in thinking it was necessary to provide security to attract the right type of young men into the profession. The right type of men were willing to undergo hardship in the early stages of their career to achieve success.

Dr. SEGAL said that many doctors were born into the profession in a state of security and these were those who could not be expected to specialize and obtain the best positions. They were always the best men. The Bill sought to ensure that some of the deserving elements of the community should not be deprived of an opportunity to render their best services in the field of medicine because of lack of security.

Mr. WILLINK said that in this matter the Opposition were so much concerned with the doctors as with the interests of the patient. He was convinced that patients would be less satisfied by a salaried service, and he did not think people would come to their family doctor being a salaried servant. Just at the moment when the general practitioner service was being made available to everyone the Minister was destroying a substantial amount of the relationship between the patient and the family doctor. The only issue was whether the service was to be received from a doctor in a part-salaried position or from one whose income was in relation to the zeal and interest displayed.

The motion to disagree with the Lords amendment was carried by 303 votes to 128—Government majority 175.

The remaining amendments made by the House of Commons were agreed to.

MEDICAL MISCELLANY

Private Practice by Medical Officers of Health

In the House of Lords on Oct. 28 Lord MERTON said how many county districts in England and Wales medical officers of health were still permitted to engage in private practice.

PENICILLIN...

in
Respiratory Infections

Penicillin by Inhalation

MOST of the organisms responsible for common infections of the respiratory system, such as pneumococci, streptococci, staphylococci, and D. catarrhalis, are penicillin sensitive.

In acute infections, such as lobar pneumonia, the intra-muscular injection of 15,000 units of penicillin in sterile solution three-hourly day and night for five days has given satisfactory results.

In empyema the injection of 30,000 to 50,000 units of penicillin in 30 to 50 c.c.m. of solution into the pleural space, repeated in 24 to 48 hours, has given valuable results.

In more chronic conditions such as bronchiectasis and chronic bronchitis, penicillin by inhalation has proved of definite value.

the Successful Treatment of

FIBROSITIS

and certain cases of

RHEUMATISM

with

NOVUTOX

Mass of evidence has accumulated to show that the treatment of fibrositis and certain cases of Rheumatism with Novutox injections affords not only complete restoration of function with immediate freedom from pain, but also, in many cases, early recovery.

Tested members of the medical profession are invited to write a copy of a Thesis on "THE INJECTION TREATMENT OF FIBROSITIS—with special reference to: Lumbago, Muscular Rheumatism (Acute and Chronic), Muscular Pain (of Traumatic origin)."

NOVUTOX is available in:

2-oz. and 20-oz. Bottles: 1%, 1% and 2% Solutions.
Boxes of 12 x 2 c.c. Ampoules: 1% and 2% Solutions.

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreinatoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

ARMACEUTICAL MANUFACTURING CO. LTD.
THE LABORATORIES, CHELTENHAM, GLOS.

The Original

Syrup Cocillana Compound

'COSYLAN'

is once more available in its pre-war formula and supplies are adequate. 'Cosylan' is issued in bottles of 4 and 16 fl. ozs.

FORMULA

Each fluid drachm of 'Cosylan' contains:

Tinct. Cocillana	5 mins.
Tinct. Euphorb. Pilulif.	15 mins.
Syrup Wild Lettuce	15 mins.
Fluid Extract of Squill	1 min.
Fluid Extract of Senega	1 min.
Tartarated Antimony	1/184-gr.
Cascarin, Bitterless (P., D. & Co.)	1-gr.
Menthol	1/100-gr.
Ethylmorph. Hydrochlor.	3/32-gr.

The adult dose is half to one teaspoonful, preferably undiluted, to be swallowed slowly three or four times daily.

Defence and attack against CHILBLAINS

Oral administration of calcium and vitamin D—as 'Ostocalcium'—is commonly used as a defensive measure against chilblains. A chilblain-free winter is quite possible when 'Ostocalcium' Tablets are taken regularly throughout the cold weather. If chilblains develop, however, parenteral therapy is more promptly effective. Injection of Colloidal Calcium with 'Ostelin' (vitamin D) will frequently alleviate the immediate symptoms, and the parenteral attack can be consolidated by giving 'Ostocalcium' by mouth to prevent recurrence.

COLLOIDAL CALCIUM with OSTELIN

AND

OSTOCALCIUM TABLETS

Colloidal Calcium with 'Ostelin', 6, 12 and 100 x 1 cc. ampoules. 30 cc. bottles.
'Ostocalcium' Tablets, Bottles of 50, tins of 100 and 1,000.*

BASINGSTOKE AND LONDON

A treatment of TENO-SYNOVITIS by means of Elastoplast

CASE HISTORY

On the 16th January a bricklayer, aged 31, complained of pain at the back of the wrist. It was particularly noticeable when grasping.

A radiograph revealed nothing abnormal but clinically there was synovial crepitation in the extensors.

Treatment — Fingers immobilised by posterior-anterior strips of Elastoplast binding them over a roller bandage. Another turn of Elastoplast bandage strapped the wrist. On the 23rd January there was still slight pain and Elastoplast was reapplied to the hand and wrist only.

By the 30th January there were no symptoms.

The patient returned to work after 14 days but the Elastoplast

wrist strapping was retained for a further week.

The details and illustration above are of an actual case T. J. Smith & Nephew, Ltd., manufacturers of Elastoplast, are privileged to publish this instance, typical of many in which their products have been used with success, in the belief that such authentic records will be of general interest.

In Elastoplast elastic adhesive bandages a combination of the particular adhesive spread with the remarkable STRETCH and RESILIENT properties, together provide the correct degree of compression and grip. They mould readily to any part of the body without slipping, rubbing, or constriction.

Elastoplast bandages are available in widths of 2", 2½", 3" and 4" x 5½ yd. long when stretched. Also 2" wide x 1½ yd. (stretched). Elastoplast, Elastocrepe, Iodoine and Gypsol are products of T. J. Smith & Nephew, Ltd., Hull.

which counties were these districts situated; and what steps are proposed to be taken to ensure that the whole country is served by full-time medical officers without further delay. Lord LISTOWEL replied: There are 511 county districts in England and 111 in Wales (according to the latest available information) where the medical officer of health is not restricted in engaging in private practice. These county districts are situated in all counties in England and Wales except Cambridge, Oxfordshire, Westmorland, the Isle of Wight, and Pembrokeshire. All counties except three have formulated arrangements under Section 58 of the Local Government Act, 1929, and Section 111 of the Local Government Act, 1933, for ensuring that as vacancies for medical officers of health occur in county districts the persons appointed to fill the vacancies shall be restricted from engaging in private practice. Steady progress was being made before the war in accordance with these arrangements in securing the appointment of whole-time medical officers of health not engaged in private practice, but an acute shortage of medical manpower during the war interrupted the process and from 1943 until the early part of this year appointments were normally made on a temporary basis. A number of county district councils whose proposals for full-time permanent appointments had had on that account to be deferred are now putting forward proposals for such appointments in accordance with the arrangements formulated under the Local Government Acts of 1929 and 1933. These proposals are to be considered in the light of changed circumstances, for example, the proposed modification in the duties of medical officers of health under the National Health Service proposals. In some instances it is necessary to discuss with the authorities concerned whether any alteration of the original arrangements is desirable. The Government are in full accord with the view that the employment of full-time medical officers of health throughout the country is an object to be attained with all practicable speed. They will carefully watch the position and consider what further steps are necessary in the light of experience.

The Press and Patent Medicines

During a debate on the control and ownership of the Press in the House of Commons on Oct. 29 Mr. DRIBERG said it would be unusual to see in any national newspaper an exposure or an examination of the claims of patent medicines by any scientist or doctor of standing. The newspapers exercised more censorship than they used to do over the advertisement of patent medicines. But there was still a considerable abuse and no freedom of expression about the claims of that kind of commodity was allowed in any big-circulation newspaper.

Mr. KEELING asked whether it were not the case that every daily newspaper in this country before publishing any patent medicine advertisement consulted the Advertising Association which had a special panel to "vet" all these advertisements in the advice of the medical profession or of the Pharmaceutical Society.

Mr. NALLY said that this panel paid no attention to the price of the commodity in relation to its actual value. If a charge of 2s. 6d. was made for something which the chemist could sell for 3d. the Newspaper Proprietors' Association did not trouble about that but proceeded to advertise the commodity. Mr. KEELING said the Advertising Association was influenced in its judgment on whether an advertisement should be published solely by professional advice on whether the claims put forward were legitimate or fraudulent.

Mr. DRIBERG said the factual wording of these advertisements was correct but the skill of the advertiser, the artist, and the copy-writer conveyed an impression which went beyond the actual wording of the claim. Mr. MAUDE said the proper way to control patent medicines was not to have a Royal Commission on the Press but to tackle the purveyors of patent medicines and to prevent people from selling two-pennyworth of bicarbonate of soda for 5s.

By 270 votes to 157 the House declared its opinion that a Royal Commission should be appointed to inquire into the finance, control, management, and ownership of the Press.

Streptomycin

On Oct. 29 Mr. BEVAN said medical research was being undertaken in the United States of America regarding the use of streptomycin in the treatment of tuberculosis. It would not be justifiable to adopt it for general use in this country till adequate clinical trials had been carried out to test claims made for it. Arrangements to that end were being made.

Mr. BEVAN, on Oct. 31, told Dr. BARNETT STROSS that two small plants were producing streptomycin on a very small scale in this country. None was yet available for clinical trials. Until those trials had been completed it would not be possible to assess the usefulness of the drug.

Tuberculosis Allowances.—On Oct. 24 Mr. WESTWOOD explained that family allowances were taken into account for the purpose of determining tuberculosis allowances because of the principle, accepted in all recent social legislation, that there should be no duplication of benefits payable out of public funds. The future of the Tuberculosis Allowances Scheme in relation to the new social legislation was under review, and the special needs of this class were kept in mind.

Radioactive Isotopes.—Mr. BEVAN, on Oct. 31, said that his attention had been drawn to clinical experimental work in the United States with radioactive substances, such as radioactive phosphorus and iodine in the treatment of inoperable cancerous growths. Experiments were being carried out with the small quantities of these substances available in this country. It was hoped that the quantities would shortly be increased.

Temporary Registrars.—Mr. HASTINGS, on Oct. 31, inquired whether persons who had earned and secured naturalization by service as doctors in the armed Forces during the late war but had not obtained an English medical degree would be permitted to continue in practice in this country after Jan. 1, 1947. Mr. BEVAN assumed that Mr. Hastings had in mind the position which would arise in such cases when the Temporary Medical Register came to an end on Dec. 31, 1947. Mr. Bevan said he was considering this in consultation with the Secretary of State for the Home Department and the Secretary of State for Scotland.

Central Medical War Committee.—Mr. BEVAN, on Oct. 31, told Dr. JEGGER that the duties of the Central Medical War Committee in advising on the selection of individual doctors for the Services were still heavy and it must continue in being for the present.

National Health Service Supplies.—Mr. BEVAN is considering with Mr. WILMOT, Minister of Supply, how the medical supply industries will be able to meet the increased demands when the national health proposals become law. No final arrangements can yet be made.

Universities and Colleges

UNIVERSITY OF LONDON

At a meeting of the Senate on Oct. 24 C. V. Harrison, M.D., was appointed to the University Readership in Morbid Anatomy tenable at the British Postgraduate Medical School, and M. A. Rushton, M.B., L.D.S., was appointed to the University Chair of Dental Medicine tenable at Guy's Hospital Medical School.

UNIVERSITY OF EDINBURGH

At a graduation ceremony held on Oct. 26, the following diplomas were conferred:

DIPLOMA IN PUBLIC HEALTH.—*L. S. Anderson, *H. A. Barker, *A. D. C. S. Cameron, E. Campbell, *K. H. Cheung, *P. S. Clouston, J. R. Gray, *W. W. Hutton, *R. S. Kennedy, *R. I. S. Lewis, D. A. Lowe, *D. I. McCallum, *D. McGowan, Isobel P. MacKenzie, *J. M. Mair, *W. G. Pollard, *K. D. G. Reid, *D. S. F. Robertson, R. Scott, J. E. Simpson, J. Sleight, *B. Snell, *D. Thomson.

DIPLOMA IN MEDICAL RADIOLOGY.—P. Aitken, Margaret D. Cameroo, *N. Saks, *A. C. P. D. Thomson, J. C. Wood.

* In absentia.

CONJOINT BOARD IN SCOTLAND

The following candidates, having passed the final examinations, have been admitted L.R.C.P.Ed., L.R.C.S.Ed., L.R.F.P.&S.Glas.:

Flora S. Barry, A. Blench, C. K. Brown, P. A. Clarke, E. D. Cloughley, T. Corrie, Hilda M. Davies, H. Fernbach, John Hamilton, Phaik-Lin Lim, P. A. R. Lornie, Anna Majzlis, F. R. Moreland, John McLaughlin, J. A. Pool, E. W. Russell, R. Short, E. Silverstone, H. J. Stott, P. J. Verannes, D. T. Wilson J. Zucker.

The Services

President Truman has conferred the Legion of Merit in degree of officer on Col. F. S. Gillespie, late R.A.M.C., for services as Medical Liaison Officer with U.S. Army.

The President of the U.S.A. has bestowed the Legion of Merit, Degree of Legionnaire, upon Temp. Surg. Lieut.-Cmdr. A. P. Curtin, R.N.V.R., for services to the U.S.A. during the war.

The President of the U.S.A. has conferred the Bronze Star Medal on Wing Cmdr. (Mrs.) Edna V. Butler-Jones, M.R.C.S., in recognition of valuable services rendered in connexion with the war.

Col. A. R. Moodie, T.D., has been appointed Honorary Colonel in the 51st (Highland) Division, R.A.M.C., T.A., in succession to Col. G. W. Miller, D.S.O., T.D., whose tenure of appointment has expired.

Surg. Lieut.-Cmdrs. P. de Bec Turtle and R. R. Prewer, R.N.V.R., have been awarded the R.N.V.R. Officers' Decoration.

No. 42

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct. 19.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e), Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales, and Eire.

EPIDEMIOLOGICAL NOTES

Paratyphoid in Sheffield

In the week ending Oct. 26 there were 71 additional cases of paratyphoid B notified in Sheffield C.B., as against 12 cases in the preceding week. Cases appearing since then and including some adults have brought the number of notifications up to 126 on Nov. 5. The source of the outbreak, which has chiefly affected children under 10, has still not been determined.

Discussion of Table

In *England and Wales* the incidence of scarlet fever declined by 58, while increases were recorded for measles 380, acute pneumonia 56, paratyphoid 16, dysentery 13, and whooping-cough 13.

There was a small general fall in the number of cases of scarlet fever which had been increasing continuously for the past six weeks; the largest decrease was Essex 21. The chief increases in the notifications of measles were Lancashire 212, Yorkshire West Riding 69, Kent 46, and London 44; the largest fall was Devonshire 56. The local trends of whooping-cough fluctuated and the largest variations were rises in Lancashire 50 and Norfolk 25. Of the 22 cases of paratyphoid 15 were notified in Yorkshire West Riding (Sheffield C.B. 12). Returns for diphtheria showed increases in Lancashire 12 and Glamorganshire 12 and a decrease in Warwickshire 10. A fresh outbreak of dysentery was notified in Oxfordshire. Bullington R.D. 13; the only other large total was Lancashire 11.

In *Scotland* the chief features of the returns were rises in the notifications of measles 96 and dysentery 19. The rise in cases of dysentery occurred in the burghs of Glasgow and Airdrie, where 19 and 11 cases, respectively, were notified during the week.

In *Eire* the incidence of measles increased by 17 while decreases were recorded for scarlet fever 15 and whooping-cough 12. The notifications of diarrhoea and enteritis slightly increased to 63, of which 48 were reported in Dublin C.B.

In *Northern Ireland* a further 15 cases of typhoid were reported from Armagh U.D., where last week 25 cases were notified. The notifications of whooping-cough in Belfast C.B. rose from 15 to 48.

Births in the September Quarter

The Registrar-General for England and Wales has announced that 213,135 live births were registered during the third quarter of this year. This is equivalent to a birth rate of 19.7 per 1,000, the highest recorded in any quarter since June, 1923, and is 4.1 and 4.5 above the rates for the third quarters of 1945 and 1938, the last complete pre-war year. The average rate for the September quarters during 1940-4 was 15.4.

Venereal Diseases

The incidence of venereal diseases, which are not notifiable, has in the past been estimated by the number of cases treated at the clinics. In recent years this estimate has been affected by the introduction of sulphonamides. This made it easy to arrange private rather than clinic treatment, especially for cases of gonorrhoea. Now that penicillin is superseding the sulphonamides the number attending clinics is likely to rise again.

The number of cases of early syphilis—infections of less than one year—was first recorded in 1931. From this date until 1939 a continuous fall was observed from 9,104 to 4,926. During the war this trend was reversed and a steady increase took place until 1945, when the cases reached a total of 10,741. The sex ratio also changed considerably. During 1931-9 the number of male cases was two and a half times the number of female cases. In 1945 the females infected slightly outnumbered the males. As a result of this changing distribution male cases of early syphilis in 1945 were 146% of the 1939 figure while the female cases showed an increase of 391%.

The approximate number of new infections with gonorrhoea: both civilian and Service cases, showed a similar trend, rising from 43,400 in 1939 to 58,797 in 1944. The sex incidence of this disease also changed. In 1939 there were 2.7 males to 1 female, whereas in 1944 the ratio had fallen to 1.3.

Vital Statistics in New Zealand

The following summary of vital statistics for the year 1945 shows again how favourably the figures for 1,593,513 Europeans compare with those for 98,007 Maoris. For Europeans

ternal mortality rate including deaths from septic abortion 2.24 per thousand live births, as compared with 2.71 in 14-5. After excluding deaths from septic abortion the rate is 1.95 (2.14 in 1944). Maori figures for maternal mortality : not available.

	European	Maori	Combined
th-rate per 1,000 population ..	23-22	47-38	24-62
th-rate per 1,000 population ..	10-07	16-68	10-46

th-rate, tuberculosis, all forms	3-78	37-02	5-77
er 1,000 population			

Week Ending October 26

The notifications of infectious diseases in England and Wales ring the week included: scarlet fever 1,209, whooping-cough 199, diphtheria 314, measles 2,884, acute pneumonia 436, rebronspinal fever 28, dysentery 59, acute poliomyelitis 31, ratyphoid 89, typhoid 9.

Medical News

The King, on the recommendation of the Secretary of State forotland, has approved the appointment of Dr. Hugh Brechinraigie to be a Medical Commissioner of the General Board ofontrol for Scotland. Dr. Craigie took a major part in developinge psychiatric services in the Middle East, and later became commanding officer of the Military Psychiatric Hospital, Bellsdyke,irlingshire. He is at present deputy superintendent of the Whittingim Mental Hospital, Preston, Lancashire.

A lecture entitled "The Country Doctor" will be delivered byr. William N. Pickles in the Hall of the Royal Faculty ofhysicians and Surgeons (242, St. Vincent Street, Glasgow) onWednesday, Nov. 13, at 4 p.m.

Sir Henaege Ogilvie will deliver the Bradshaw Lecture before theoyal College of Surgeons of England on Thursday, Nov. 14, atp.m. Subject: "Surgical Handicraft." The lecture is open toedical practitioners and advanced students, and tea will be servedom 4.30 p.m.

The Faculty of Radiologists announces that Sir Gordon Gordonaylor will give the Skinner Lecture, on malignant tumours of thesticle, at the Royal College of Surgeons, Lincoln's Inn Fields, onFriday, Nov. 15, at 2.30 p.m. The lecture is open to all members ofe medical profession. Other radiological meetings to be held inondon about that date have been arranged by the British Instituteof Radiology for Nov. 14, at 8 p.m., at 32, Welbeck Street, to discussindustrial skin cancer; and by the Radiological Section of theL.S.M. on Nov. 15, at 8 p.m., at 1, Wimpole Street, to discussray treatment of inflammatory diseases. A joint meeting of allthree radiological societies will take place on Dec. 13 and 14 fordiscussion on carcinoma of the stomach in all its aspects.

The Socialist Medical Association (35, Long Acre, W.C.2) hasarranged a winter programme of six lectures, to be given at 7.30 p.m. at Denison House, 296, Vauxhall Bridge Road, S.W. On Nov. 14Dr. F. R. G. Heaf will speak on social aspects of tuberculosis; onNov. 28 Dr. F. Avery Jones on social aspects of peptic ulcer; onDec. 12 Dr. J. Tyler Fox on social aspects of epilepsy; on Jan. 2Dr. A. T. M. Wilson on social aspects of medical psychology; onJan. 16 Dr. J. N. Morris on social aspects of juvenile rheumatism;and on Jan. 30 Dr. H. Joules on occupational hazards of the healthworker.

The Genetical Society announces a public lecture to be given onFriday, Nov. 22, at 5 p.m., at the London School of Hygiene andTropical Medicine, Keppel Street, W.C., by Prof. Tage Kemp,Director of the University Institute of Human Heredity, Copenhagen.Subject: "Multiple Factors in Morbid Inheritance," accompaniedby a film, "The Fat Dwarf." All interested are invited to attend.

The Food Education Society will hold a meeting in the library ofthe Royal Society of Arts, John Adam Street, Adelphi, W.C., onTuesday, Nov. 12, at 3 p.m., with Lord Horder in the chair, whenSir Jack Drummond, D.Sc., F.R.S., will give his inaugural addressas chairman of the Society.

A sessional meeting of the Royal Sanitary Institute will be heldat Nuneaton Council House on Saturday, Nov. 16, at 10 a.m., whenpapers will be read on "Housing in Relation to Health" and"Environmental Hygiene and Some Problems of the Future."

Wednesday clinical evenings at the Royal Hampshire CountyHospital, Winchester, will be held in the Board Room at 8.30 p.m.on Nov. 20, Dec. 18, Jan. 15, Feb. 19, and March 19.

In connexion with the meeting for inauguration of an Associationof Plastic Surgeons on Nov. 20, it has now been arranged to dineat the Royal College of Surgeons after the meeting. Diners areasked to notify the secretary, Sir Harold Gillies, 149, HarleyStreet, W.1.

The Empire Rheumatism Council has arranged a week-end courseon rheumatic diseases to be held at the Red Cross RheumatismClinic, Peto Place, Marylebone Road, N.W., on Nov. 22, 23, and24. The course is designed for medical students and consists ofthirteen lectures. Programmes may be obtained from the medicalsecretary, Empire Rheumatism Council, Tavistock House (North),Tavistock Square, W.C.1. The closing date for admission to thecourse is Oct. 31.

The Northern Area Surgeons of the St. John Ambulance Brigadewill meet in conference on Sundays, Nov. 10 and 17, at theBonnington Hotel, Southampton Row, W.C., from 2.30 to 6 p.m.

A medical conference will take place in Accra, Gold Coast, fromNov. 12 to 16 between representatives of the Colonial Office andthe French Ministry of France, Overseas. The Portuguese Govern-ment and the Government of Liberia are sending observers. Theconference will include medical experts from four British WestAfrican territories, Nigeria, the Gold Coast, Sierra Leone, and theGambia, from French West Africa, from Equatorial Africa and theFrench Cameroons, from the Belgian Congo, and from PortugueseGuinea and Liberia. The primary object of the conference is toarrive at an agreement regarding the local exchange of informationon medical and health questions of importance throughout WestAfrica and for more effective co-ordination and collaboration oflocal services engaged in the fight against disease.

New methods of attack on gastric cancer will be outlined at aconference to be held on Dec. 5 and 6 at the Billings Hospital,University of Chicago. Arranged by the Gastric Cancer Committeeof the National Advisory Cancer Council, this will be the thirdlarge conference on gastric cancer to be sponsored by the Council.The first one was held in 1940 at the National Cancer Institute ofthe National Institute of Health, which is the research division ofthe U.S. Public Health Service. As a result of these previousconferences, research departments of a number of schools ofmedicine and hospitals have taken a greatly increased interest inthe problem of gastric cancer.

The study of the "science of relationships" is the effort to con-sider the whole man in all his contacts with his environment in itsphysical, mental, and spiritual aspects. To further this study theChurch Missionary Society is calling the third Rural Life Con-ference which will be held at High Leigh, Hoddesdon, Herts, Jan7-10, 1947. It is hoped to assemble doctors, farmers, clergy,teachers, social workers from over-seas and at home to listen toeminent speakers on the problems of rural life and to join in dis-cussing in various commissions subjects related to the addresses.Applications for registration forms should be sent to the actingsecretary, Rural Life Conference, C.M. House, 6, Salisbury SquareE.C.4.

The 38th annual meeting of the Medical Benevolent Society for theEast and North Ridings of the County of York was held at Hullon Sept. 25, with the President, Mr. T. Ritchie Rodger, in the chair.The honorary secretary reported the death of two members, Dr. CHoward Jackman (a member since 1909 and honorary secretary from1933 to 1939) and Dr. George Sandys Belas (a member since 1922and president during 1944-5). Sympathy with the relatives wasexpressed. The honorary treasurer reported the Society as in asound financial state, and the one application for help submittedto the meeting was granted. Three new members were elected; aswere the following officers: President, Mr. T. Ritchie Rodger, Hull;Vice-president, Dr. G. F. Longbottom, Middlesbrough; President-elect, Mr. R. B. Blair, Hull; Hon. Treasurer, Col. N. T. Whitehead,Hull; Hon. Secretary, Dr. W. W. A. Kelly, 92, Micklegate, York.

A new organization to promote the education and rehabilitationof children suffering from cerebral palsy was formed at a meetingin the City Education Offices in Edinburgh on Oct. 31. Theorganization is to be called the Scottish Council for the Care ofSpastic Children, and the first president is to be Sir John Fraser, Bt.,Principal of Edinburgh University. An executive committee hasbeen formed under the chairmanship of the Rev. William Graham,secretary of Inverness-shire Education Committee, and Dr. Alex.Fraser, M.O.H. for Inverness-shire, has been appointed secretary.

Mr. Frederick Newland-Pedley, F.R.C.S., of Lago di Como, Italy,founder of the Dental School of Guy's Hospital, who died on May 4,1944, left £63,416 7s. 5d. After a number of bequests he left the residue of his estate to Guy's Hospital, for prizes and scholarshipsin connexion with the Dental School. Dr. John Price Williams, ofAmbleside, left £5,296 10s. 7d.; Dr. Arthur Walton Peake, ofBristol, £34,826 2s.; Mr. Edward Baines, of Whitby, Yorks.,£29,405 6s. 3d.; and Dr. George Arbour Stephens, of Swansea,£27,116 14s. 11d.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Attology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Hyoscine for Seasickness

Q.—Is it safe to give hyoscine as a prophylactic for seasickness in a nursing mother?

A.—Hyoscine is rapidly destroyed in the tissues and only minute traces appear in the milk; thus there should be no danger in prescribing it for a nursing mother. Holling, McArdle, and Trotter (*Lancet*, 1944, 1, 127) investigated the value of drugs in the prevention of seasickness and, of many tested, found hyoscine by far the most effective.

A satisfactory method is to give a tablet containing 1/200 gr. (0.32 mg.) by mouth four hours before sailing, again at the time of sailing, and subsequently four-hourly until four tablets have been taken. On the second and third days 1/200 gr. is taken at 8 a.m., 12 noon, and 4 p.m. More than four tablets in twenty-four hours should never be prescribed. It is seldom necessary to continue after the 8 a.m. tablet on the third day.

Amphetamine for Air Travel

Q.—A patient complains of a severe pain in her temples when travelling by air. It comes on only when descending from a height and remains for some hours after landing. Can you suggest any remedy, and, if she persists in flying, will permanent injury to the ears be likely to result?

A.—This is most unlikely to produce any permanent injury. It is possible that relief may be obtained by the use of an amphetamine inhaler while at high altitude to ease any lack of complete patency of all cavities during descent.

Antrum Infections and Idiopathic Steatorrhoea

Q.—Is it known whether a chronically infected antrum has any effect on adult idiopathic steatorrhoea, and are the risks of operation in such cases greater than in a normal person?

A.—There is no evidence that the presence of a chronically infected antrum has any significant effect upon the course of idiopathic steatorrhoea. Such patients do not appear to be more liable to infection than other members of the community. If a serious degree of anaemia is present the blood should be raised to an adequate level by transfusion. If operation is indicated, on account of the antrum alone, it should be carried out.

M.D.U. Malta

Q.—Can you give any information regarding qualification in medicine in Malta, and/or reciprocity with this country? Can you add any further relevant details, such as schools of medicine, qualifications bestowed, etc., or indicate a source to which I may apply for further particulars?

A.—Reciprocity has existed between this country and Malta since 1901. Any person in possession of the qualification of Doctor of Medicine granted by the Royal University of Malta (M.D.U. Malta), and of the Governor's licence to practise in Malta, is eligible for registration in the Medical Register kept by the General Medical Council, upon complying with the usual requirements of the Council as to evidence of character and on payment of the necessary fee. Further particulars may be obtained from the Dean of the Faculty of Medicine of the University.

Penicillin for Latent Syphilis

Q.—Can penicillin be used to accelerate the cure of latent syphilis contracted four years ago?

A.—Yes. A total dosage of 4,000,000 units is recommended. This may be given by means of intramuscular injections each of 30,000 to 40,000 units three-hourly, or of 300,000 units twice in the twenty-four hours. Arsenic and bismuth should be employed as well immediately after completing the course of penicillin; the amounts will depend on the results of blood tests. In any case, it would be wise to have the cerebrospinal fluid tested without delay, and adjust continuation treatment according to the findings.

Subtrochanteric Osteotomy

Q.—A male aged 70 has advanced osteo-arthritis of the left hip, which is painful and more or less fixed in partial flexion, with marked adduction. Would subtrochanteric osteotomy, if successful mechanically, relieve or remove the pain, which is at present almost constant?

A.—Subtrochanteric osteotomy is of recognized value in osteo-arthritis of the hip for the correction of deformity. It is probable that pain would also be relieved, because of the abnormal posture and the stresses connected therewith are important factors in its production; but it would not be justifiable to give an absolute undertaking that pain would completely disappear, as there may be other influences at work. It would, however, appear that such an operation should be recommended as making life much more comfortable.

Varicose Veins and Menstruation

Q.—A woman of 34, with one child aged 3, complains that since her confinement each period is preceded, and accompanied for the first two days, by severe aching in the left foot and leg. She has a slightly varicose vein, which is tender. Erythematous patches appear on the inner aspect of the foot, where there is a small venous swelling which is also tender to the touch. Can you advise me as to diagnosis and treatment?

A.—The blood supply to the pelvic organs is increased before and during menstruation, and the circulation in the legs is usually affected as well. This latter is not obvious as a rule but tends to show up if the circulation is already impaired. Thus varicose veins are nearly always more distended and painful at this time. All the signs described in this problem could be explained on the basis of a vascular change of this sort. The fact that the symptoms date from pregnancy may be because the varicose veins only developed or became worse during that pregnancy, or the patient may have suffered a deep thrombosis during the puerperium. Treatment in the first place should be directed to the varicose veins, bearing in mind this last possibility.

Risk of Tetanus in Factories

Q.—Is a factory medical officer treating small but contaminated wounds justified in omitting to inject tetanus antitoxin? Does this involve any medico-legal risk?

A.—The injection of tetanus antitoxin in factory workers with minor injuries is not an accepted medical practice, and the medical officer who does not do so would not ordinarily be penalized if cases of tetanus should occur following a minor injury in the workshop. Where the risk is greater, as in a penetrating wound in a worker in an outside yard where contamination with dust or dirt containing the dried excreta of domestic animals is likely, antitoxin might well be given. It seems to be the general experience that tetanus rarely occurs among factory workers suffering minor or even more serious injury.

Pertussis Vaccine

Q.—Is there a phase of increased susceptibility following the injection of pertussis vaccine? Should a smaller initial dose be given in epidemics to those who may be contacts?

A.—It must be pointed out that there is as yet no unanimity about the value of active immunization against pertussis. The whole problem is being studied by the Medical Research Council. There is no evidence to suggest that a child

ceptibility to pertussis will be temporarily increased after action of vaccine. The so-called negative phase is not wadays regarded as having any practical significance apart from the fact that, if the inoculated person has some systemic infection after an injection, for example, of T.A.B. vaccine, he may be temporarily less resistant to infections of any kind. Whether an injection of vaccine in an individual already in the early stages of infection will aggravate the illness, as has been claimed to be the case in typhoid fever ("provocation" theory), is a matter for argument. For pertussis it has been the custom in Denmark to give small doses of vaccine at two-three-day intervals to contact children who may be already in the early stages of infection, with apparently good effect. For young children who are intimately exposed to the risk of infection some arrangement for combined passive-active immunization, as has proved useful in diphtheria, would probably be most effective.

Gold Wishbone Contraceptive Appliance

Q.—A married woman with three children has asked me to help her with a gold wishbone contraceptive appliance. The diminutive Dutch cap and a chemical pessary have proved ineffective in her case. I should like to know: (1) How are these appliances fitted? (2) Are they worn continuously? (3) Are they really 100% safe? (4) Do they cause cervicitis to any significant degree? (5) Are they as dangerous as they are made out to be?

A.—1. The appliance is usually fitted by compressing the arms of the pessary together and slipping a small gelatin cap over the air tips. They can then be pushed through the cervix into the cavity of the uterus. There the gelatin melts and the arms ring apart to grip the uterine walls.

2. It is worn continuously for varying periods, but preferably for not longer than three weeks, after which it is removed, left out for a few days to give the uterus time to recover from any injury, and then reinserted. Although the stem and cap are hollow and allow menstrual blood to escape, the best time to remove it is just before menstruation, reinserting it when the flow has ceased.

3. No. They do not prevent conception but act by inducing early abortion or by preventing implantation of a fertilized ovum. Even so pregnancy is not always interrupted, and has been known to go to term with the "wishbone" still in place.

4. They certainly cause cervicitis to some degree, but what is more important is that they damage the endometrium. This may be followed by infection which is not always confined to the uterus.

5. Yes. The questioner should also note the objections to the "silver" or "Grafenberg" ring, a slightly different contraceptive device, about which the Family Planning Association has recently issued a warning (Oct. 19, p. 599).

INCOME TAX

Miscellaneous Inquiries

M. O. asks for information on a number of points, the nature of which will be seen from the following replies.

* (1) Whether a wife acts as assistant or partner to her husband does not affect the total amount of tax payable, except that in the first year in which she acts as assistant she is liable to tax for that year, but, as the husband is assessed on the basis of the previous year's profits, it does not reduce his liability until the following year.

(2) The fact that "the garage is in a ruinous state" does not affect the Land Tax, and the Rating Authorities are not likely to make any reduction unless it is clearly so damaged as to be practically destroyed.

(3) The cost of repairing those portions of the premises which are used in the practice is allowable—except in so far as it may be claimable as "War Damage."

(4) Broadly, payments for accident and sickness benefit are not allowable for income tax purposes. A reply as to the payments to the pension fund for widows cannot be given without particulars as to the identity of the fund and the precise nature of the contract.

(5) The salary as locum tenens comes within P.A.Y.E., but the local Tax Office may exclude it and bring it into the general receipts if application is made in time.

(6) Necessary travelling expenses between various clinics at which paid professional work is done are allowable.

(7) As regards books, the cost of keeping the private reference books up to date is allowable.

(8) The cost of replacing professional equipment is allowable, but the original cost is in the nature of capital outlay and is not allowable. Instruments are not regarded as plant and machinery and do not carry a claim to depreciation. Such personal instruments as aids to sight or hearing are outside the income tax field altogether.

(9) The cost of repairs to or replacement of a typewriter are allowable.

(10) The income tax consequences of marriage take effect from the date of the marriage whether the spouses then lived together or not.

Cost of Maid

"XYZ" considers that about half the time of the maid is spent on the professional work, but says that if she were not required for that work the cost of the sort of maid that would be kept would be less than half the cost of the present maid.

* The invariable rule adopted is to divide the actual cost according to the ratio of the time spent on the professional side of the maid's work. It is unlikely that the inspector—or if an appeal were made, the Commissioners—would adopt a different basis on the hypothesis suggested.

"Free Board and Lodgings"

"Locum" received a salary and "free board and lodging" while acting as locum tenens. The inspector of taxes regards the value of the free board and lodgings as assessable.

* Benefits provided in kind and not transferable into money are not assessable, and *prima facie* the inspector's action is incorrect. The position would be different if, for instance, "Locum" was primarily liable to a third party for the cost of his board and lodging and his principal paid for him; that would be tantamount to a payment in cash to "Locum."

Car Transactions

R. joined a practice in January, 1946. The accounts of the practice are made up to April 5 each year. He bought a car for £400 in March, 1946, used it for three months, and then sold it for £500. He bought another car in July for £250 and spent £50 on repairing it. It is presumed that the practice is not being treated for income tax purposes as a new one as from the date on which R. joined it.

* The income tax assessments will, of course, be made on the firm and not separately on the individual partners: the question is what will be the effect of these transactions on the firm's assessment. The answer is that they will not affect the assessment for 1946-7, but as regards 1947-8 the first car will give rise to a "balancing charge" of £500-£400=£100, and the second car to an "initial allowance" of 20% of £250=£50 plus a wear-and-tear allowance of 25% of £250=£62 10s., together with the deduction of the £50 spent on repairs. That is on the assumption that the second car remains in use up to April 5, 1947.

J. M. is employed by a County Council. Under the terms of his agreement he must own a car and use it on the Council's work. He used a County Council vehicle until he was able, on August 25, 1946, to buy a car for £575. What allowances is he entitled to for 1946-7 and 1947-8?

* 1946-7.—(a) Initial allowance—20% of £575=£115, and (b) wear-and-tear allowance of 25% of £575 for the period Aug. 25, 1946, to April 5, 1947—say, £88; total £203. 1947-8.—Wear-and-tear allowance—25% of (£575-£203=) £372—i.e., £93. The above must be taken with the following qualifications—(i) J. M. will have to bring into credit the mileage allowance he receives less running costs, insurance and other car expenses; (ii) as the statute authorizes the deduction of such expenses only as are "necessary" in the performance of the duties, some adjustment may be called for if the car is unnecessarily commodious, etc.; and (iii) the expenses incurred and the above allowances will be restricted (if necessary) to allow for any private use of the car.

G. S. has a car which he bought for £200 five years ago but "is now worth £800." He wants to bring it into the practice in order to claim depreciation on it—up till now it has been stored and used occasionally "but not as a practice car." At what value can it be brought in?

* The depreciation allowance is given for a car in use for the purposes of the practice at the end of the year which provides the basis for the assessment. Assuming that the practice accounts are made up as at Dec. 31, and that the car is brought into use before Dec. 31, 1946, the earliest income tax year for which a claim can be made is 1947-8. The allowances are given to meet the amount spent in acquiring the car, and the total allowances cannot exceed the actual cost to the individual claiming the allowance. The maximum value on which the allowances should be based is £200.

LETTERS, NOTES, ETC.

Midwife and Doctor: Conduct of Labour

Dr. A. W. PURDIE (London) writes: The question put to Miss Meave Kenny by the midwives to whom she was lecturing on "The Prevention of Puerperal Sepsis" (Oct. 26, p. 638) is an important one. Obviously these midwives are in the habit of wearing masks while conducting confinements. From time to time I am called, in a consultant capacity, to attend at a confinement which is taking place either in the patient's own home or in a nursing home. From my own observation I know that many doctors and midwives do not wear a mask while conducting a labour. The more senior may not yet have begun to use masks. The younger and more junior, who have been taught their use, can easily slip into bad habits. Are there not potent remedies nowadays against puerperal infection if it should occur? Why then trouble to wear a mask? All would probably agree, if challenged, that prevention is better than cure. But everyone who teaches medical students or student-nurses knows how important is constant and untiring repetition in driving home essential facts. And even then how easily these are forgotten! The well-informed criticism of Miss Kenny's audience should be encouraged. It is a tribute both to the keenness of its members and to the early teaching which they received. I must confess to some surprise, however, on reading what Miss Kenny suggested the midwife should do when a doctor, whom she had called in, did not wear a mask. A man may be led but he will not be driven. I should have answered: "If I were a midwife I should carry a spare mask in my bag. If the doctor whom I called in did not wear a mask I should say casually to him, 'I see you have forgotten to bring a mask, Dr. X. I have a spare one with me. Perhaps you would care to use it.'"

Dr. W. ARNOTT (Totland Bay) writes: Dr. Meave Kenny (Oct. 26, p. 638) makes the amazing suggestion that it is the duty of a midwife to walk out of a confinement ease and report to the M.O.H. if a doctor with whom she is attending declines to wear a mask at her request. I would submit an emphatic negative to this and maintain that no action on her part is called for. The doctor's responsibility is towards his patient, and his action will be ruled by his conscience, judgment, and experience. I have been sorry to see signs of distress of mind of late in midwives on this score: it is so unnecessary. In forty years of midwifery and over 1,000 cases I have not seen a case of puerperal fever attributable to respiratory infection. The few I have had, countable on the fingers of one hand, other than a few calls on midwives' orders to pyrexia cases, have arisen from accidental and extraneous causes such as the occurrence of scarlet fever in the house. I have not worn a mask except on odd occasions when suffering from a catarrhal cold. I am willing to submit my record to Dr. Kenny or to the Central Midwives Board, and my conscience is clear. The profession should stand firm against any muzzling order such as Dr. Kenny proposes.

Dr. W. EDWARDS (Ashstead) writes: Dr. Meave Kenny (Oct. 26, p. 638) draws a pathetic picture of 120 distressed midwives appealing for her advice. What are they to do if they call in a doctor to a difficult confinement and the doctor won't wear a mask? Not for Dr. Kenny the obvious retort that they should mind their own business, realize that the responsibility rests now with the doctor, and just try to be helpful. Dr. Kenny took a grim view. She advised these worthy women to draw the doctor's attention to his fall from grace. If he should then be obdurate, they should inform him that the consequences were on his own head, and withdraw from the case. At which the County Medical Officer of Health, doubtless an experienced obstetrician, could searce forbear to cheer. This, presumably, is the sort of gestapo spirit we shall have to endure in the State medical service. Those dressed in brief authority over us will not be satisfied in telling midwives to strike if the rules are not obeyed. Theatre sisters will walk out if surgeons wear the wrong-sized gloves. Chemists will shut their shops if prescriptions are undated. Physiotherapists will throw in the talcum if asked to use infra-red when the rules say ultra-violet. What a lovely spirit of co-operation we are going to have!

Recurrent Bee Stings

Dr. MARGARET D. WRIGHT (London, W.) writes: The paragraph on recurrent bee stings (Sept. 28, p. 479) prompts me to record my experiences. Having been subject to more than one alarming anaphylactic attack, the most serious of which entailed a week in bed, I gave up bee-keeping myself. More than 20 years later I acquired more stocks and after a number of minor stings had another severe anaphylactic attack which was treated with adrenaline. The treatment suggested using ephedrine hydrochloride prophylactically at least half an hour before opening any hive. I have used this steadily over the last three summers, and, although on some occasions I have been badly stung, yet the pre-

monitory symptoms of an anaphylactic attack have never been more pronounced than the tingling felt throughout the palms of the hands and the soles of the feet, together with slight swelling of the lips. No major discomfort has been experienced and the swelling has subsided in a day or two. Swelling does tend to be severe, however, from any occasional sting. It is hard for a bee-keeper to give up his hobby and I myself have no hesitation in carrying on with this protection.

Sex Determination

Dr. F. T. B. LQVEGROVE (Wongan Hills, W. Australia) writes: In the *Journal* (Aug. 10, p. 216) I notice mention of Dawson's theory that one ovary makes male-producing eggs and the other female. If your expert's statement that there is no scientific basis for the theory merely means that it remains to be proved or disproved (despite the unassailable theory quoted in the preceding paragraph) the following case may be of interest to him. In June, 1938, I performed a laparotomy on a woman in whom I found an abdomen full of blood. The right ovary was split almost in half, presumably due to a ruptured Graafian follicle. The most satisfactory way to control the bleeding was to remove the ovary, and I did so. This woman has since had three children—two boys and one girl.

Doctor's "Lines" for Glucose, etc.

Mr. ROBERT S. WHITELAW, M.P.S., writes: A doctor's "line" on account of its "time honoured" illegibility has been the subject of many a good-humoured story both inside and out of the profession. My immediate appeal to doctors does not concern their handwriting (though that is still the cause for frequent profanity) so much as the simple "line" given for commodities in short supply. I am sure I am voicing the opinion of most pharmacists when I say that shortages would not be so acute if doctors generally gave more time to considering necessity before granting a prescription for glucose, olive oil, malted milk, etc. I have had one "signed order" which, if fulfilled, would practically exhaust my entire quota of glucose. This is of course exceptional, but it serves as an illustration of the fact that better supplies would be available for genuine requirements' if "lines" were only given when medically required.

Cables from Canada

The following cable has been sent to the British Medical Association by Dr. George Ramsay, President of the College of Physicians and Surgeons of Ontario: "Canadian medical profession regret misunderstanding of references concerning British nurses made by Hamilton Bailey at London, Ontario, meeting. His reference was small part of broad discussion of national shortages and particularly stressed nurses' weariness following extended war effort. We did not regard it in any way as reflection on professional efficiency and loyalty."

Mrs. Hamilton Bailey has also received a cable from Mr. C. M. Carruthers, F.R.C.S., in the course of which he said: "Mr. Bailey at no time during his lecture or otherwise made a statement derogatory to the nursing profession in Great Britain or any other country."

Apparatus for Trichlorethylene In Midwifery

Dr. JOHN W. SCHOLEY writes from Sleaford, Lincs: As I have so far been quite unable to obtain a Clover's inhaler for use with trichlorethylene in midwifery I would welcome any readers' views on the use of an Oxford vaporizer in the same capacity using trichlorethylene as the anaesthetic.

Digital Traction

Mr. H. P. MALCOLM, M.Ch. (Belfast), writes: Dr. K. M. MacLeod (Oct. 26, p. 614) will find traction from the nails described in *The Thomas Splint and its Modifications in the Treatment of Fractures*, by Meurice Sinclair, C.M.G., published in 1927 by the Oxford Press.

"In My Fashion"

Mr. P. A. MORAN (Oxford University) writes: The reviewer of my father's book *In My Fashion* did not read the book very carefully. My father did not serve with the Italian army in Abyssinia. He went there with a party of American and foreign journalists.

Varicose Ulcers and Penicillin

Dr. P. L. RENOUF (Hayle) writes: Referring to Dr. W. T. E. Blackmore's letter (Sept. 28, p. 480), I am not convinced that cleansing a varicose ulcer thoroughly with warm saline, and applying a dressing of penicillin cream once weekly, adds any beneficial effect to the overlying tight supporting bandage from foot to knee described by Dr. Blackmore. Nor can I see from my own experience, in the majority of cases, that anything but delay is caused by withholding surgery and injection until the ulcer is healed by less effective methods.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 9 1946

CRIMINAL JUSTICE BILL

RECOMMENDATIONS BY THE B.M.A.

the document printed below containing observations on, and recommendations for amendment of, certain clauses in the Criminal Justice Bill, has been drawn up by the British Medical Association and sent to the Home Office by the Magistrates Association.

General.—Throughout the Bill the substitution of the words "agree to mental treatment" for "required to submit to mental treatment" is recommended.

Clause 5 (5) (c).—"the expression 'local authority' means the local authority liable in accordance with the provisions of this Act to defray the expenses of the probation committee, or, where two or more local authorities are so liable, such one of those authorities as may by agreement between them be appointed to act, either generally or in a particular case, for the purpose of this section." After the initial use of the words "local authority" the word "authority" might well be substituted for "local authority" in the definition since the subsequent use of the term "local authority" appears to be redundant and likely to lead to difficulty.

Clause 10 (1).—"The Secretary of State may provide places to be called 'remand centres,' in which persons of not less than fourteen nor under twenty-three years of age, who have been remanded or committed for trial or sentence and are not released on bail, may be detained." (a) This provision, which covers the dangerous gap after 17 years of age, is welcomed. (b) In view of the wide range of ages covered, provision should be made for the grading and grouping of the persons concerned.

Clause 10 (2).—"The Secretary of State shall provide in remand centres facilities for the observation of any person detained therein whose case a report may be desirable for the assistance of the court in determining the most suitable method of dealing with his case." It is important that where a report is required to assess the mental condition of an offender in a remand centre, it should be made by a psychiatrist with adequate knowledge of mental deficiency and child psychiatry.

Clause 11 (1).—"The Secretary of State may provide, in addition to the remand homes provided by the councils of counties and county boroughs, one or more remand homes, to be called State remand homes. . . ." Provision for two types of remand homes is unnecessary and all remand homes should be provided and maintained by the State.

Clause 11 (2).—"The Secretary of State shall provide in State remand homes, and the councils of counties and county boroughs may provide in remand homes provided for their areas, facilities for the observation of any person under seventeen years of age on whose mental condition a medical report may be desirable for the assistance of the court in determining the most suitable method of dealing with his case, and any such council may, if facilities for observation are available at any other institution or place, arrange for the use of those facilities for the observation of any such person as aforesaid who is detained in a remand home provided for the area of that council." (a) The provision should be made obligatory, not permissive. (b) The facilities should be available for persons up to 23 years of age.

Clause 19 (1).—"Where a court is of opinion that it is expedient to make a probation order and is satisfied on the evidence of a duly qualified medical practitioner that the mental condition of the offender is such as requires and as may be susceptible to treatment but is not such as to justify his being certified as a person of unsound mind under the Lunacy and Mental Treatment Acts, 1890 or 1930, or as a mental defective under the Mental Deficiency Acts, 1913 to 1938, the court shall have power to include in the probation order a provision requiring the probationer to submit, for such period not extending beyond twelve months from the date of the order as may be specified therein, to treatment by or under the direction of a duly qualified medical practitioner with a view to the improvement of the probationer's mental condition." (a) The provision should apply to supervision as well as probation orders. (b) The

period should not be limited to 12 months. The order should be reviewed after 12 months, and if considered desirable extended for a further period or varied to suit the circumstances.

Clause 19 (5) (b).—"while the probationer is under treatment as a voluntary patient or as a resident patient, the probation officer responsible for his supervision shall only carry out the supervision to such extent as may be necessary in connexion with the variation or cancellation of the said provision." It is undesirable that the probation officer's responsibility should be so limited, as she may often be able to play a useful part in the restoration of the patient. It is suggested that the Bill should indicate that the probation officer should be encouraged to befriend the patient while under treatment.

Clause 26 (1).—"If within three months of the making of a probation order an application is made to the supervising court by the probation officer responsible for the supervision of the probationer and the court is satisfied on the evidence of a duly qualified medical practitioner that the probationer is a person in whose case a provision could, if the probation order were then being made, be included therein under section nineteen of this Act, the court may, with the consent of the probationer, insert in the probation order a provision requiring the probationer to submit, for such period not extending beyond twelve months from the date of the amending order as may be specified therein, to any such treatment as is mentioned in the said section nineteen." It is suggested that the opening words should read: "If at any time during the year . . ."

Clause 26 (3).—"Where the probation officer responsible for the supervision of a probationer receives a report made under the last foregoing subsection, or is of opinion that the probationer cannot for any reason continue to receive treatment for his mental condition by or under the direction of the person, or at the place, specified in the probation order, or in charge of the person so specified, the probation officer shall make application to the supervising court and that court may, with the consent of the probationer, make such amendment of the order as appears to the court to be proper, or may by order cancel the provision requiring the probationer to submit to such treatment as aforesaid." The period should not be limited to 12 months. The order should be reviewed after 12 months, and if considered desirable extended for a further period or varied to suit the circumstances.

Clause 26 (4).—"An order under this section cancelling a provision may be made without summoning the probationer." The probationer should nevertheless be notified of the cancellation.

Clause 42 (1).—"Where a person is charged before a court of summary jurisdiction with an offence for which the court has power to pass a sentence of imprisonment, and the court is satisfied that the offence has been committed but is of opinion that an inquiry ought to be made into the mental condition of the offender before the method of dealing with him is determined, the court shall remand him in custody or on bail (with or without sureties) for such period or periods, not exceeding three weeks in the case of any single period, as the court thinks necessary to enable a medical examination and report to be made." (a) The group of persons for which the provision is made is not comprehensive enough. It should include separation and maintenance cases, young persons beyond control, and persons requiring care or protection. (b) Provision should be made for the payment of a fee for the medical examination and report. Funds should be made available for the purpose. (c) It is suggested that the words "by a duly qualified medical practitioner" be added to the end of the Clause.

Clause 43 (1).—"Where a person is charged before a court of summary jurisdiction with an offence for which that court has power to pass a sentence of imprisonment, and the court is satisfied that the offence has been committed and is satisfied on the evidence of at least two duly qualified medical practitioners that the offender is of unsound mind and is also satisfied that he is a proper person to be detained, the court may, in lieu of dealing with him in any other manner, exercise the powers conferred by this section." The clause should be extended to cover mental defectives who cannot be treated under the Mental Treatment Act.

Clauses 43 (3) and 43 (5) (b).—"If no such arrangements as aforesaid have been made, the court may order him to be taken to and received in a hospital or part of a hospital approved for the purposes

of section nineteen of the Mental Treatment Act, 1930, by the council of the county or county borough comprising the petty sessional division for which the court acts, or in a workhouse belonging to the said council, or may, if it is satisfied that proper care will be taken of the offender in the meantime, adjourn the case with a view to enabling such arrangements as aforesaid to be made; and where the court adjourns the case in accordance with this subsection and it is notified, before the expiration of the period of the adjournment, that a reception order has been made in relation to the offender, it may discharge him without requiring his further appearance." "The provisions of the Lunacy and Mental Treatment Acts, 1890 to 1930, shall have effect as if—(b) any order made under subsection (3) of this section for the reception of an offender in a hospital or part of a hospital or workhouse were an order made under subsection (1) of section twenty-one of the said Act." The words "suitable institution" should be substituted for "workhouse."

PROTECTION OF PANEL PRACTICES IN LONDON

At the last meeting of the London Protection of Practices Committee the following report of the administrative officer of the London Insurance Bureau (the bureau which operates the panel side of the Protection of Practices Scheme in London) was submitted, and the committee felt that it was of such general interest that other areas would like to see it.

On Dec. 31, 1943, the number of insured persons on the lists of absentee practitioners who were credited to acting practitioners was 111,071. At that time the number of absentees was 380. After that date the numbers declined quarter by quarter as practitioners returned to their respective practices, and by March 31, 1946, the number of insured persons had been reduced to 31,538 and the number of absentee practitioners to 126.

The capitation fee per annum paid in respect of the insured persons on the lists of acting practitioners was as follows:

Year	Rate per Unit
1939 (September to December—4 months only)	8s. 1-376d.
1940	11s. 9-253d.
1941	11s. 8-367d.
1942	9s. 11-404d.
1943	8s. 5-447d.
1944	8s. 4d.
1945	8s. 3-815d.
1946 (January to March—3 months only)	4s. 8-8d.

An examination of the lists of 94 of the practitioners who have returned has been made. It discloses a total National Health Insurance credit at the date of return of 70,454, and of that number 47,688 persons, or 67% of the lists of the absentees, had been accepted by acting practitioners. The figure affords an interesting index as to the number of insured persons on the list of an insurance practitioner who required treatment assuming, of course, that only those persons in need of treatment were accepted. I am inclined to doubt the strict accuracy of this assumption.

Further analysis of the number of 47,688 persons shows a very wide distribution among acting practitioners. At the beginning it was thought that the patients of an absentee practitioner would distribute themselves among, say, four or six neighbouring practitioners, whereas, taking all cases into consideration, it has been ascertained that to provide treatment for over 100 insured persons on the lists of absentees the services of six acting practitioners were enlisted. Owing to the proximity to the surgery of an absentee practitioner or for some other special reason, acting practitioners in some cases accepted responsibility for more than 100 of the insured persons of a neighbouring absentee. If these cases, which represent nearly one-half of those under notice, are excluded, the remainder shows an even wider distribution—viz., twelve acting practitioners to every 100 provisional patients.

The practice of an insurance practitioner in London ordinarily extends two miles from his surgery (North, South, East, and West) with the exception that the River Thames forms a natural line of demarcation. This gives a "practice area" of twelve and a half square miles. Patients on the boundary of a "practice area" were free to select an acting practitioner two miles from such boundary, and the area within which some patients of an absentee practitioner might conveniently find an acting practitioner was thus increased from twelve and a half square miles to fifty square miles. This may partially account for the very wide distribution of patients. I may say that every effort was made to afford protection in a very strict sense to the practice of an absentee practitioner, and in a few cases in which doubt might have arisen as to the validity of a removal transfer the benefit of that doubt was given to the practitioner who was absent.

I append details of a few cases which are typical, showing the distribution of an absentee practitioner's patients. These relate only, of course, to the practices of practitioners who have resumed

practice, but there is no reason to think that the details are unrepresentative of the lists of all practitioners. Attention is also drawn to the number of acting practitioners who accepted the insured persons of particular absentees. These varied considerably.

Practitioner No.	Figure of Credit on Date of Return	No. of Insured Persons who Secured Acceptance by Acting Practitioners	No. of Acting Practitioners	Further Details
(a) 3,535	1,873	1,322	79	Two practitioners accepted 675 persons
(b) 3,749	1,578	1,083	74	Four practitioners accepted 653 persons; the remainder (430) went to 73 practitioners
(c) 2,706	3,165	2,275	54	2,036 persons of this practice went to one practitioner; the remainder (239) were accepted by 53 practitioners
(d) 4,909	715	520	54	Two practitioners accepted 335 persons; the remainder (185) were accepted by 52 practitioners
(e) 6,992	929	396	53	One practitioner accepted 129 persons; the remainder (267) were distributed among 52 practitioners
(f) 5,259	372	259	50	Only a small practice but 50 practitioners were involved
(g) 5,414	1,750	1,385	36	One practitioner accepted 1,312 persons; the remainder (73) distributed themselves among 35 practitioners
(h) 6,428	636	385	31	One practitioner accepted 332 persons; the remainder (53) were distributed among 30 practitioners
(i) 2,616	373	164	25	128 persons were accepted by one practitioner and 24 practitioners were involved in the remainder (36)
(j) 6,021	493	225	22	One practitioner accepted 199 persons; the remainder (26) were distributed among 21 practitioners
(k) 6,282	31	21	13	Only a very small practice but 13 practitioners were involved
(l) 7,718	26	9	6	Only 9 persons were concerned but these were accepted by 6 practitioners
(m) 6,429	8	5	4	Four practitioners accepted 5 persons between them.

A detailed analysis has been made of 94 cases, and the result shows that over 60 practitioners were involved in 5 cases, between 50 and 60 practitioners in 12 cases, between 41 and 50 practitioners in 16 cases, and between 31 and 40 practitioners in 18 cases.

It need hardly be mentioned that the work of notifying practitioners of the return of absentees was largely increased owing to the manner in which insured persons distributed themselves among acting practitioners, and in my opinion the very wide distribution of patients which occurred was a complete revelation.

J. C. GILBERT,
Administrative Officer.

MEDICAL SERVICES IN CEYLON

B.M.A. Branch Plan for Reconstruction

The Ceylon Branch of the British Medical Association has worked out a scheme for the reconstruction of the medical services of the island. The aims of the scheme are (1) to provide for an efficient system of medical education and services directed towards the attainment of health, prevention of disease, and relief of sickness, (2) to make available to every person all necessary medical services, and (3) to bring into existence a comprehensive medical service to effect these objects, with the necessary safeguards for the prospects and interests of the profession.

Shortage of Personnel

The scheme, which was agreed to unanimously at a meeting of the Branch early in the year, addresses itself first to the most urgent problem, that of the shortage of doctors. In Ceylon there is one doctor to nearly 9,000 people. Excluding 85 medical officers of health, there are about 700 doctors for a population of more than six millions; 400 of these doctors are in the Government service and 300 in private practice. Three thousand

is needed if the British minimum of one doctor to 2,000 people is to be attained. The output from Ceylon Medical College is some 28 doctors a year. Measures are suggested for increasing the teaching accommodation at the General Hospital, Colombo, which at present has not room for more than 100 students working at the same time. Recommendations are also made for postgraduate courses, and for a diploma in tropical medicine and public health, with a department at the University.

The shortage of nurses is also a dire problem. They number only 550, and if the minimum British standard of one nurse to 100 hospital beds were adopted, 4,000 nurses would be needed for the present accommodation in Ceylon hospitals, not to speak of the large increase in that accommodation which is likely to be necessary. Recommendations are made for recruitment, including the creation of a service of male nurses and of assistant nurses. Midwives, too, are scarce, and proposals are made for an increase to 300 in the number of pupils at the De Silva Maternity Hospital, where about 9,000 deliveries take place every year, and for the establishment of three other small training hospitals.

Hospital Needs

The report goes on to assess the hospital needs of Colombo, the capital, and the nine Provinces, based on density of population and mortality. It is urged that at the General Hospital, Colombo, there should be set up an advisory board, composed of Government officials and representatives of the industrial and business community, also a specially constituted board of management, with official and unofficial members, and a medical staff committee. Each of the Provinces should have one central general hospital staffed on the same lines as the metropolitan, with an advisory board, special departments, and so on; every district hospital with 50 beds should have at least one medical officer, and cottage and rural hospitals should be distributed throughout the island on a definite plan based on accessibility and density of population. Proposals are made for a maternity and child welfare service, including an increase in the very small number of obstetric specialists at present available, the appointment of two qualified paediatricians, and the setting up of neonatal clinics in every maternity unit.

Planning of Health Services

For the general planning of the services under a Ministry of Health two chief officers are proposed, one to have supervision of the preventive and the other of the curative side. The reason for not combining the two services is the fear that the organization would become preponderantly curative or preventive according to the bent of a single director. District councils of health are proposed, representing localities, and on these the medical practitioners and district health officers would serve. These district bodies would submit their plans to the Ministry, which would co-ordinate them in its general plan for the whole country.

Each group of schools with 6,000 or so pupils should have a medical officer attached to it, so that children could be examined on admission and annually and necessary prophylactic treatment be given. A forward movement is called for to combat tuberculosis, this to include the mass radiography of factory and office employees, investigation of contact infection in homes, special care of pregnant women with tuberculosis, improvement of the economic conditions of tuberculous patients, and adequate provision of beds. Another proposal is for the co-ordination of the present measures for dealing with malaria problems under the control of a central officer with institute and laboratory personnel. The creation of a department of industrial medicine is suggested because of the number of industries in the island which involve health hazards. For dealing with mental diseases a psychiatric clinic near the General Hospital, Colombo, is recommended, also a child guidance centre, a psychopathic hospital and observation home, and an asylum for the criminal insane. A dental service of a very thorough character is also outlined.

Doctors' Salaries

The present scale of pay of medical officers is compared with that of officers in corresponding Government services, and it is shown that after ten years of employment a higher salary

is paid in the police or the irrigation department than is attainable in twenty or more years in the medical department. After thirty years in the medical department the salary of an officer rises only to Rs. 9,000 (about £670). It is felt that there is no reason why the salaries of medical officers should be lower than those of the legal officers of the Crown, whose training is not so prolonged and is certainly not more exacting than that of medical officers. Therefore the new scale of salaries proposed for medical officers is the same as that for Crown Counsel, namely, Rs. 6,540 rising to Rs. 12,000 (£490 to £900), and for the highest posts among medical officers the same salary should be paid as for the legal officers of the Crown, namely £2,400 per annum.

The report is fortified at many points by references to the position in Great Britain, and it is evident that in working out the scheme the Ceylon Branch has studied very carefully the achievements and tendencies in the Western world.

PANEL CONFERENCE DINNER

At the close of the Panel Conference the representatives assembled at dinner at the Connaught Rooms, the members of the Insurance Acts Committee being the guests. Dr. J. A. Brown was in the chair, and among those present was Sir Hugh Lett, the President of the Association. Just upon 200 sat down at the tables, and the occasion was marked by great cheerfulness, to which the Scottish contingent contributed in a very large degree.

Dr. D. F. HUTCHINSON proposed the health of the Insurance Acts Committee and spoke of the outstanding leadership which insurance practitioners had enjoyed. Dr. E. A. GREGG, in responding, claimed for his committee that it was the best in the Association. The knowledge and aptitude of its members, he said, put their chairman in constant peril. He stressed again the necessity for the maintenance of unity in the profession.

The Dain Testimonial Fund

Dr. Gregg then formally presented to Dr. Guy Dain the Dain Testimonial Fund—a belated presentation, for the Fund had been in existence for some time and had already done good if modest service for the assistance of sons and daughters of medical practitioners in need of financial help for educational purposes. At the same time he handed to Dr. Dain, in token form, a tangible gift in the shape of three pieces of furniture of his choice—a corner cabinet, a table, and a desk. Dr. Gregg recalled Dr. Dain's outstanding services in the I.A.C. long before he reached the chair. It was due to his insistence that in 1923 the offer of the then Minister of a capitation fee of 8s. for five years or 8s. 6d. for three years was rejected, and an independent inquiry insisted upon, as a result of which an award of 9s. was made. There was another court of inquiry in 1937, when Dr. Dain, then chairman of the committee, presented the case with great efficiency and clarity, and countered with the skill of an advocate certain very questionable evidence presented on the other side. The Dain Testimonial Fund was completed in 1939 and would have been presented to him at the Panel Conference of that year but for the outbreak of war. At the moment it stood at rather less than £5,000. He formally handed it over to him with the great appreciation of all insurance practitioners for his exceptional services.

Dr. DAIN said that when the testimonial was organized he had felt, having received the Gold Medal of the Association as well, that his work for his profession might be considered to be completed, but events had turned out otherwise. He had done no more for the profession than many others, but the limelight had happened to fall on him and not on them. That being so, he felt when the testimonial fund was mooted that he should not accept the money for himself, but for some purpose of good in the profession, and the assistance of the children of doctors who had fallen upon misfortune suggested itself. The income from the Fund at present was small, but some deserving cases had been helped, and others had been referred to sources where help could be obtained. Many Panel Committees, for example, had funds which might be used for the educational assistance of doctors in their areas. He heartily

thanked all those concerned for the kindness shown to him. He had never understood those who said, when asked to do something for their profession or for some public cause, that they would probably never be thanked for it. One did not do this kind of thing for thanks, but for enjoyment and for the opportunities of fellowship and friendship which such service opened out. But in his own case the thanks had been forthcoming too, and he was grateful.

Dr. R. W. COCKSHUTT, in a witty speech, proposed the health of the Chairman, and Dr. BROWN replied with an amusing appreciation of his four colleagues—Drs. Dain, Wand, Gregg, and Hill—who had accompanied him to the Ministry when the invitation to reopen discussions on the capitation fee was received. Dr. CHARLES HILL, responding to the toast of "The silent service"—the secretaries and staff of the B.M.A.—concluded with a tribute to the excellent clerical staff of the Association, especially the clerk of their own Committee, Mr. Scrivener. Dr. L. S. POTTER, Secretary of the Committee, also made a brief acknowledgment, and the proceedings concluded with a vote of thanks to the Dinner Committee, proposed by Dr. J. A. IRELAND.

As a result of an appeal made from the top table a sum of £99 7s. was contributed to the Dain Testimonial Fund from the assembled hosts and guests.

HEARD AT HEADQUARTERS

The Plebiscite

The National Health Service Bill will presumably receive Royal Assent before this issue of the *Journal* reaches its readers. Immediately after the passing of the Act the form for the plebiscite will be sent out from headquarters to every member of the profession. Only one question is asked on the form and it admits of no answer save "Yes" or "No." The question is: "Do you desire the Negotiating Committee to enter into discussions with the Minister on the regulations authorized by the National Health Service Act?" The only other entries to be made on the paper are a statement as to the number of years the voter has been qualified and an indication in the appropriate space of the kind of professional work in which he is wholly or predominantly engaged. The voting papers sent to members in Scotland and Northern Ireland will bear a distinctive mark in order that they may be separately classified. With the form there goes out a report of the Negotiating Committee and a covering letter embodying the decisions and voting of the Representative Body on the important issues, an appeal to all practitioners to vote whatever their views, and a reminder that the profession is free to enter or not to enter the Service.

Reformed Procedure of the G.M.C.

The B.M.A. Council was faced with a heavy agenda at its meeting this week. The number of reports of committees to be considered was 23, and there was much other business. All this related to the ordinary work of the Association, not touching, except incidentally, on the question of the National Health Service. One report which came up for consideration was from the committee which has been considering the reform of the disciplinary procedure of the General Medical Council. All the bodies concerned with this subject seem to be agreed on the setting up of a disciplinary tribunal much smaller than the Council itself. The draft medical bill of the G.M.C. proposes a tribunal of 19. The defence societies suggest one of 7, possibly having in mind the new jury figure. The special committee of the B.M.A. makes no recommendation on this point, but seems to favour some figure between these two. In any event it will be a drastic change from the procedure which has obtained for nearly ninety years whereby the whole Council of 40 or more has listened to these cases. One consequence of any altered disciplinary procedure of this kind will be an increase in the number of direct representatives so as to ensure that enough members of particular knowledge of general prac-

tice problems will be available both for the disciplinary tribunal and for the penal cases committee which will undertake the earlier sifting of complaints.

A Day with the Students

The annual meeting of the British Medical Students' Association, apart altogether from the irruption of Mr. Bevan into their midst, was a very prolonged affair. The students, having already devoted part of Friday and part of Saturday to their business, sat through the whole of Sunday, from 10 in the morning until 6 at night, and only the determination of the president, Mr. D. R. Cook of Newcastle, prevented them from rounding the clock. The talk ranged over such subjects as increased tuition fees and students' expenses (here one was glad to hear some expressions of sympathy for parents), the de-reservation of medical students (it was stated that in one school students who failed once in one part of the first examination are forthwith de-reserved), the supply of bodies for dissection, international relations, liaison with other student group proposals for a medical postal library, and for obtaining periodical medical literature at a reduced rate. Some of the students wanted to go outside their own field and help the nurses to organize a students' association, but as the B.M.S.A. is only five years old it was felt that at present it had better keep behind its own plough. The students who gathered at the conference from most of the schools of Great Britain were a very able and wideawake lot of young people, who knew their own mind and were not afraid to speak it.

Reminders of Two Great Men

Headquarters has just received posthumous reminders of two men, contemporaries, each of whom in high office did great work for the Association, and whose names will live in its history. One such reminder was a cheque for £1,000 bequeathed free of all duty from the estate of the late Mr. Bishop Harman to be devoted to the increase of the clinical prize which the late Treasurer of the Association initiated just before the war. The other was a small portrait of the late Sir Kaye Le Fleming which he had desired the Association should have, together with his silver presentation porringer, the latter given in the hope that perhaps it might start a collection of plate for the B.M.A.

Industrial Health Research and the T.U.C.

Dr. H. B. Morgan, M.P., had a tilt at Mr. Herbert Morrison at the T.U.C. at Brighton over the question of industrial health research. The T.U.C. had passed on to the Lord President of the Council a resolution that the powers and funds of the Industrial Health Research Council should be increased to enable it to carry out widely extended research and for the establishment of an institute for the purpose. Mr. Morrison had replied that the lack of suitable men rather than the lack of money was the main obstacle to expansion. Dr. Morgan said that this reply was so unsatisfactory as to be ludicrous. Of course there was a lack of suitable men to do industrial research according to the methods of the present "clique" running it, but there were in the country medical men of progressive mind who were available. These men would not be chosen because they did not fit into a particular groove. The problem of the relationship between occupation and disease, said Dr. Morgan, had been grossly neglected. Mr. Morrison had said that the work of industrial health research would be actively pursued. Dr. Morgan wanted to know where. The London Hospital was doing excellent work but in the other teaching schools, except Birmingham, practically no research was done. Under the pressure of its programme the T.U.C. took no further action.

RETURN TO PRACTICE

The Central Medical War Committee announces that the following has resumed civilian practice: Dr. H. Everley Jones, O.B.E., 11, Park Road West, Wolverhampton.

Correspondence

Bureaucratic Control

SIR,—The letter from the Minister of Health to Mr. Eardley Holland published in the *Journal* of Oct. 12 (p. 550) illustrates something of what we may expect in a Government Service th laymen ignorantly legislating for us. The Minister proposes to have an "obstetrician," presumably a M.R.C.O.G., in charge of each antenatal clinic run by local authorities. This assumes first a fantastic surplus of obstetric specialists, and then a gross underpayment not commensurate with their skill else a gross waste of the people's money if they are paid equally. The routine work of antenatal clinics at present is very competently done by G.P.s and local government M.O.s of similar professional status, who have had special experience of the work. The percentage of cases requiring the opinion of a consultant is very small indeed, and perfectly well dealt with by referring them to a central clinic. I speak after some experience as M.O. to an antenatal clinic. This talk of obstetric specialists to every clinic is pure propaganda to the lay public, who do not understand and are only the poor mugs who have foot the bill. Mr. Holland wisely made no comment, but his letter reached the press, where it was meant to go. On the same principle of using a steam-hammer to crack a nut, I expect that the Minister will be appointing full-time experienced paediatricians to run the child welfare clinics to bring their powerful intellects to bear on the problem of little illie's spots and the important issue of whether "baby ought to be cutting her teeth now because the book says so and I don't see any sign of them, doctor"—problems very important to the mother anxious to do her best for her child, but quite within the abilities of any average practitioner to deal with. With a paediatrician in the central clinic for real problems. While on the subject of propaganda, I wonder if Lord Jowitt so simple-minded as really to believe, as he stated in the Lords on Oct. 8, that the National Health Service involved no bureaucratic control and would not involve a single additional civil servant? He also stated that no doctor was to be compelled by direct or indirect pressure to join, and he was to be in no way interfered with. As the alternative to joining is, as a noble lord well knows, either starvation or emigration. I wonder what he does mean by "indirect pressure"? Churchill was all too right when he envisaged the slave State wards which we are steadily being impelled by the men who are supposed to be the servants of the people, but who see themselves and act as the masters. Thinking men are reluctantly forced to see the analogy to the commencement of the Nazi regime, and it may not be long till no editor will dare to publish a letter like this lest he find himself in the concentration camp. This is the logical progress of the present régime, and if this letter, or the length of which I must apologize, brings but one more man into the fold of the resistance movement a useful purpose will have been served.—I am, etc.,

Pogtrefact.

J. S. LAURIE.

Receipt against Dictatorship

SIR,—The medical profession has by a united front won a great victory. Mr. Bevan has found that he cannot impose his will on a free people and has been forced to climb down and agree to implement the Spens Report. Let us make no mistake, this is only the first round, and the fight for justice and professional freedom is not yet won. My conviction has always been that, in the face of a united front, the dictatorial methods of Mr. Bevan will always fail. The Minister of Health refused to negotiate with the medical profession prior to introducing his Health Service Bill into Parliament and refused to incorporate the basic principles of the B.M.A. into the same. The fact that the Bill, as it now stands, will probably become law makes no difference to our stand for freedom. New laws can be easily introduced to give effect to our demands for incorporation of our principles.

I am confident that if the medical profession once again stands firm and refuses to co-operate until we are assured our right to practise as free men, we will again triumph. It is a basic principle of our democracy that a man shall have the

right to work where and when he pleases. Heartened by our recent victory and assured of the rights of our cause, I appeal to the profession to once again "stand firm" and present a united front to Mr. Bevan. It may mean a temporary hardship for some, but in the end it will benefit all—not only doctors, but patients also. In the face of a united profession Mr. Bevan will be again forced to climb down, and the fight for professional freedom will be triumphant.—I am, etc.,

Birmingham.

MARK J. BRADLAW.

Mutual Confidence

SIR,—For successful elaboration of the National Health Service Bill the good will of the profession will be essential. This implies mutual confidence. After our recent experience a vote would produce a 99% result of "No confidence" in the present Minister of Health. Bullying and bad faith will wreck any hope of a sound start. The Prime Minister will be wise to appoint a man we can trust and talk to and work with. This is not politics, it is just plain horse sense, for at the best the bulk of the profession views much of this Bill with distrust and misgiving. To us it is not an agreed measure.—I am, etc.,

Newton Ferrers.

W. F. BENSTED-SMITH.

A Tactical Withdrawal

SIR,—Let us note the wise move of the Minister to give way on panel capitation rate before the obvious danger of defeat. Let us beware that we are not caught on the rebound in the bigger matter to come. Some men may almost feel under a compulsion, as the panel cheque enlarges, but let not money blind us now or hereafter. I have no doubt that, financially, the Act may work out all right, but let us have no delusions about our freedom if we accept. The Act must be amended.—I am, etc.,

Newquay.

J. P. O'SHEA.

Trade Union for Doctors?

SIR,—On the question of the Health Service Bill I consider that action on this matter resolves itself into one of two alternatives: (1) sitting back and hoping for the best from the Government; (2) forming a trade union, which will be in a position to insist on negotiations with the Government and failing a satisfactory settlement will be in a position to organize opposition to the Health Bill. I can see no other practical means by which the medical profession can protect either the public or itself, or prevent the Government riding rough-shod over it both now or at a future date.

Finally, may I point out that as under the Health Bill we shall lose our independence and become State employees it becomes logical for us to arm ourselves with the only weapon with which the employee has been able to keep in check the employer, namely, the trade union.—I am, etc.,

Swansea

L. A. SYLVESTER

H.M. Forces Appointments

ROYAL NAVY

Surg. Cmdrs. G. G. Newman and J. J. Keevil, D.S.O., have been placed on the retired list.

ROYAL NAVAL VOLUNTEER RESERVE

Prob. Temp. Surg. Lieuts. H. J. P. Davies and G. E. Mavor to be Temp. Surg. Lieuts.

ARMY

Col. H. C. D. Rankin, C.I.E., O.B.E., late R.A.M.C., has retired on retired pay and has been granted the honorary rank of Major-Gen.

Cols. R. K. Mallam, O.B.E., and A. A. M. Davies, late R.A.M.C., retired, have retired on retired pay and have been granted the honorary rank of Brig.

Col. F. S. Gillespie, late R.A.M.C., having attained the age for retirement, has been retained on the Active List supernumerary.

Cols. F. G. Flood, O.B.E., M.C., and R. H. Alexander, M.C., late R.A.M.C., having completed four years in the rank, are retained on the Active List supernumerary.

Col. J. B. Fotheringham, late R.A.M.C., has retired on retired pay on account of disability.

Lieut.-Cols. W. W. S. Sharpe, R. S. Dickie, and A. R. Oram, O.B.E., M.C., from R.A.M.C., to be Cols.

Majors G. B. F. Churchill and A. E. B. Jones, retired pay, R.A.M.C., have been restored to the rank of Lieut.-Col., on ceasing to be employed.

Capt. J. D. Paterson, half pay list, late R.A.M.C., has retired on retired pay on account of disability, and has been granted the honorary rank of Major.

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

War Subs. Capt. (Miss) M. M. Shepherd has relinquished her commission and has been granted the honorary rank of major. (Substituted for the notification in a *Supplement* to the *London Gazette* dated June 11.)

Association Notices

Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of fifty guineas, is again open for competition. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of fifty guineas.

2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1946. The prize will be awarded at the Annual General Meeting of the Association to be held in 1947.

5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.

6. If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto, and enclosing the candidate's name and address.

8. The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal*, or for presentation to the appropriate Section of the Annual Meeting of the Association.

9. Inquiries relative to the prize should be addressed to the Secretary.

Diary of Central Meetings

NOVEMBER

19. Tues. Undergraduate Subcommittee: (Film Committee), 2 p.m.

Branch and Division Meetings to be Held

AYRSHIRE DIVISION.—At Ayrshire Central Hospital (Infectious Diseases Section), Irvine, Sunday, Nov. 17, 7 p.m. Clinical Meeting.

KINGSTON-ON-THAMES DIVISION.—At Kingston County Hospital, Kingston-on-Thames, Tuesday, Nov. 12, 7.45 p.m. Clinical Evening. Cases will be demonstrated by the hospital staff.

WAKEFIELD, PONTEFRAC, AND CASTLEFORD DIVISION.—At Clayton Hospital, Wakefield, Thursday, Nov. 14, 8.15 p.m. Mr. A. J. C. Latchmore: The Acute Abdomen.

Meetings of Branches and Divisions

SUNDERLAND DIVISION

A very well-attended meeting in the scientific programme of the Sunderland Division was held on Oct. 13 at the Royal Infirmary, Sunderland.

A film, demonstrating pentothal anaesthesia and showing very fully how to deal with anaesthetic emergencies, was introduced by Dr. F. YOUNG, after a brief history of anaesthetics during the last 100 years. Dr. H. J. BELL showed an infant suffering from congenital syphilis which had been under treatment for 7 weeks and which showed

remarkable response to treatment by penicillin by mouth. The cases of failure of the circulation of the lower limbs were shown Dr. D. R. CRAMB. The address by Prof. R. V. BRADLAW, Newcastle, on "Oral Pathology of Interest to General Practitioners" was beautifully illustrated by remarkably clear, coloured slides, showed how extremely important was the proper study and scrutiny of lesions of the mouth.

POSTGRADUATE NEWS

The Fellowship of Medicine announces a week's course in obstetrics and gynaecology, for general practitioners, to be held at Qu Charlotte's Maternity Hospital and Chelsea Hospital for Women daily from Nov. 25 to 30.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Thurs., 5 p.m. Bradshaw Lecture by Sir Heneage Ogilvy Surgical Handicraft.

ROYAL SOCIETY OF MEDICINE

Section of *Psychiatry*.—Tues., 5.30 p.m. Paper by Dr. H. Eysenck: The measurement of personality.

Section of *Physical Medicine*.—Wed., 4.30 p.m. Paper by Sir A. Page: The uses of physiotherapy in an accident service.

Section of *Ophthalmology*.—Thurs., 5 p.m. (Cases at 4.30 p.m.) Discussion: Eye signs in malignant nasopharyngeal tumour. Openers: Dr. Godtfredsen (Denmark) and Mr. E. D. D. Day. Short paper by Mr. Frank W. Law: Ring scotoma after retrobulbar neuritis.

Section of *Obstetrics and Gynaecology*.—Fri., 8 p.m. Discussion: Stress incontinence in micturition. Openers: Messrs. Ever Williams and Terence Millin.

Section of *Radiology*.—Fri., 8 p.m. Discussion: The x-ray treatment of inflammatory diseases. Openers: Miss M. S. Cripps, M. Baker, Dr. Freund, and Dr. N. S. Finzi.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—Tues., 5 p.m. Dr. H. Corsi: Diseases of the Nails. Thurs., 5 p.m. Dr. Sydney Thomson: Animal Diseases Communicable to Man.

FACULTY OF RADIOLOGISTS.—At Royal College of Surgeons, Lincoln's Inn Fields, W.C.—Fri., 2.30 p.m. The Skinner Lecture by Gordon Gordon-Taylor: On Malignant Tumours of the Testicle.

WEEKLY POSTGRADUATE DIARY

BLACKPOOL: VICTORIA HOSPITAL.—Thurs., 8 p.m. Mr. Thurs: Experiences in War Surgery as applied to Civilian Practice.

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Edinburgh Royal Infirmary, Tues., 5 p.m. Mr. Angus Sinclair: The Interdependence of Biology and Other Branches of the Higher Learning.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS, 58, Queen Anne's Street, W.—Fri., 5 p.m. Dr. J. M. H. Campbell: The Role in Pregnancy.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—Mon., 8.30 p.m. Discussion: The Field of Research in Industrial Health. To be introduced by Dr. E. R. A. Merewell.

APPOINTMENTS

BOWYER, H. W., M.D., Honorary Assistant Physician to Out-patients Bolton Royal Infirmary.

CHELSEA HOSPITAL FOR WOMEN.—Surgeon to Out-patients, A. B. Evi. F.R.C.S. Anaesthetists, H. Woodfield-Davies, L.M.S.S.A., G. C. St. M.R.C.S., L.R.C.P. Chief Assistants, T. Jackson, F.R.C.S., T. L. T. St. F.R.C.S., R. B. K. Rickford, M.D., F.R.C.S., G. W. Williams, F.R.C.S.

EMPIRE RHEUMATISM COUNCIL.—Registrars to the Council: D. P. Nichols M.B., M.R.C.P. (at West London Hospital); Duncan Shiers, M.B., B.S. (at Royal Mineral Water Hospital, Bath).

ROYAL LIVERPOOL UNITED HOSPITAL.—At David Lewis Northern Hospital Branch: Honorary Assistant Surgeon, W. M. Beattie, M.Chir., F.R.C.S.

SWANN, W. G., M.D., D.P.H., Deputy Medical Superintendent Officer Health and Deputy Port Medical Officer, County Borough of Belfast.

SWANSEA GENERAL AND EYE HOSPITAL.—Radiologist, K. Mendl, M.D., M.R.R.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or 12 Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

FERNANDEZ.—On Oct. 29, 1946, at The Willows, Bramley, Yorks, to Dr. and Mrs. Alexander Fernandez, a son.

MILNER.—On Oct. 26, 1946, to Dorothy (née Galloway), wife of John F. M. Milner, M.D., 452, Heysham Road, Heysham, a son.

PARKINSON.—On Oct. 29, 1946, at Lorna Lodge, Manchester, to Margaret, wife of Dr. John S. Parkinson, a son.

STUART-HARRIS.—On Nov. 2, 1946, at Sheffield, to Marjorie, wife of Prof. C. H. Stuart-Harris, a sister for Graham.

DEATHS

ELLIOTT.—On Oct. 2, 1946, at 3, Clarendon Gardens, Tunbridge Wells, Andrew Royston Elliott, M.D., of Crowborough, aged 55 years.

VAKIL.—On Oct. 23, 1946, at 71, Compayne Gardens, N.W.6 (formerly of 18, Coram Street, W.C.1), Chuni Lal B. Vakil, M.R.C.S., L.R.C.P., aged 63

PURE PENICILLIN IN OPHTHALMOLOGY

BY

ARNOLD SORSBY, M.D., F.R.C.S.

Research Professor in Ophthalmology, Royal College of Surgeons and Royal Eye Hospital

AND

JOSEPH UNGAR, M.D.

Research Division, Glaxo Laboratories

Until recent months supplies of penicillin in current use contained some 80 to 90% of impurities. In contrast most of the samples now generally obtainable contain a concentration of penicillin of up to 80%, and limited quantities of pure penicillin are becoming available.

Pure penicillin in calcium or sodium salt is a white crystalline substance devoid of any yellowish tinge. It is freely soluble and is more stable than commercial (impure) penicillin. In the dry form pure penicillin remains stable when kept at room temperature over a period of many months. Aqueous solutions remain active for fourteen days when kept at room temperature under sterile conditions, and retain full potency for up to four weeks when kept on ice. One milligramme of pure penicillin corresponds to 1,660 Oxford units.

The use of penicillin in ophthalmology, and particularly in intraocular infections, is still limited by considerable difficulties. In the first place, penicillin administered systemically in the usual clinical doses does not penetrate into the interior of the eye. Secondly, commercial penicillin instilled locally into the conjunctival sac in high concentrations is not well tolerated. There are discomfort, conjunctival hyperaemia, and, in extreme cases, damage to the corneal epithelium; moreover, with tolerated concentrations there is no penetration through the cornea into the interior of the eye. To overcome the obstacles to the passage of the drug into the interior of the eye, penicillin has been employed as subconjunctival and intravitreal injections, and iontophoresis of solution instilled into the conjunctival sac has been practised, but only with indifferent results. The limit of tolerance to subconjunctival injections, though varying with different samples of commercial penicillin, is about 600 to 2,000 units in 0.5 ml. of water. With such doses the intraocular concentrations of penicillin are again low (only a trace in the aqueous, according to Struble and Bellows (1944), who employed 2,500 units in the dog; though, in man, Rycroft (1945) obtained higher values by the use of 4,000 units subconjunctivally—0 to 3 units per ml. in five instances, and 10, 15, and 20 units in three more). Intravitreal injection of commercial penicillin is badly borne by the experimental animal (v. Sallmann, Meyer, and Di Grandi, 1944; Sorsby, 1945; Mann, 1946), and this procedure has distinct clinical disadvantages. Iontophoresis as advocated by v. Sallmann and Meyer (1944) also presents clinical difficulties, and is only doubtfully valid on theoretical grounds (Hamilton-Paterson, 1946). Since the value of penicillin as a local therapeutic agent is limited by the inability of the eye to support large doses of the commercial product, and since intolerance varies directly with the amount of impurity present, a study of tolerance of the eye to pure penicillin was undertaken, followed by preliminary investigations of the levels of concentration that can be reached intraocularly and of the effect of local medication on experimental intraocular infections. These results have been assessed against those obtained both experi-

mentally by the systemic administration of massive doses of commercial penicillin and clinically by the use of pure penicillin locally.

Experimental Studies on Pure Penicillin

Rabbits were used throughout. Guinea-pigs were also used at first, but proved unsatisfactory, particularly when intraocular fluids had to be collected, and were therefore discarded. The rabbits were of a mixed breed and generally six months old, with an average weight of 1,500 g. The concentration of penicillin in the eye fluids, blood, and tissue extracts was estimated by the standard capillary tube method, as described by Fleming. Where ointment was introduced into the conjunctival sac, 0.1 ml. (=0.1 g.) was delivered into the lower fornix from a syringe with a wide-bore needle, and spread evenly over the globe through the closed lids; before aqueous was withdrawn for assessing the concentration of penicillin the conjunctival sac was thoroughly irrigated. Where penicillin was injected into the vitreous, the needle was entered at the equator of the proptosed eye and the drug injected centrally; a similar technique was used for introducing infection into the vitreous. Subconjunctival injections were made by the usual clinical method, and fluid from the aqueous was collected by limbal puncture (subconjunctivally), also in the proptosed eye. In assessing the concentration of penicillin in solid tissues, the parts were minced with scissors on a watch-glass, placed in 1 ml. of saline (2 ml. in the case of the sclerotic), and allowed to stand overnight in a refrigerator; the supernatant fluid was then tested.

Tolerance

Pure penicillin in aqueous solution in concentrations of 10,000, 25,000, 50,000, and 100,000 units/ml. was well tolerated when two or three drops were instilled into the conjunctival sac at ten intervals of three minutes. There was no obvious irritability, nor any flushing of the eye. Likewise pure penicillin in ointment form was well borne in concentrations of 500, 1,000, 2,000, 4,000, 8,000, 25,000, 50,000, and 100,000 units per gramme. The ointment was made up in two different bases, one being "eucerin" L.M. base, and the other a specially prepared mixture of petroleum jelly and liquid paraffin (90 and 10 parts of each respectively). Some ointment still remained in the conjunctival sac after half an hour. Subconjunctival injections of 0.5 ml. of water containing 25,000 and 50,000 units of pure penicillin were also well tolerated. There was no reaction around the bleb produced by the injection, and the bleb had mostly disappeared within three to four hours. The vitreous too tolerated direct injection of pure penicillin: 0.1 ml. of saline containing 5,000 units (50,000 units/ml.) and 0.2 ml. containing 10,000 units produced a visible "globule" in the vitreous, with but little reaction around it and no ophthalmoscopically visible changes. Apart

from some scattering of the globule after six months (the total period of observation) there was practically no reaction of the vitreous or the globe as a whole.

These observations suggested that, in contrast to commercial penicillin, the pure product is remarkably well tolerated by the eye, so that ocular intolerance is not a factor of any significance in limiting its use. It should, however, be borne in mind that concentrated solutions of pure penicillin should be made up in water rather than saline; watery solutions containing 20,000 to 50,000 units of pure penicillin per ml. are isotonic with 0.9% sodium chloride, while saline solutions of such concentration are distinctly hypertonic (Ungar and Denston, 1946).

Concentration in Interior of Eye

In the Primary Aqueous (Chart 1).—The level of penicillin in the aqueous obtained at different time intervals (a) after a single instillation of penicillin ointment in the conjunctival sac, and (b) after subconjunctival injection, was determined.

CHART 1.—Penicillin levels in the primary aqueous of the rabbit after administrations by different routes.

(a) For instillation of pure penicillin ointment the base used was a mixture of petroleum jelly and liquid paraffin, as already indicated. Table 1 shows that penicillin penetrates in therapeutic levels through the cornea when ointments of high concentrations are used. Each reading in the table represents

TABLE 1.—Level of Penicillin (Units/ml.) in Primary Aqueous on Instillation of 0.1 g. of Concentrated Ointments of Pure Penicillin into Conjunctival Sac

Concentration (units/g.)	At 1/2 hr.	At 1 hr.	At 2 hrs.	At 2 1/2 hrs.	At 3 hrs.	At 4 hrs.	At 4 1/2 hrs.	At 5 hrs.
25,000	0.4	1.5, 3	0.125, 0.25, 0.25	0	0, 0	0, 0	0, 0	0
50,000	0.4	1.5, 2, 2	0.125, 0.125	0	0, 0	0, 0	0, 0	0
100,000	0.4	4, 4, 8	1.1	0	0, 0	0, 0	0, 0	0

a single estimate, and the 44 readings recorded all refer to primary aqueous. These findings suggest that the more concentrated the ointment the higher is the concentration of penicillin in the aqueous and that a therapeutic level is sustained for 2 1/2 hours and possibly longer.

(b) The level of penicillin in the primary aqueous was also determined at different time intervals after the injection subconjunctivally of 25,000 units of pure penicillin in 0.5 ml. of water. As can be seen from the first column in Table II, adequate levels are quickly reached in the aqueous and maintained for at least 6 hours, and possibly longer. That the levels of penicillin reached and maintained by this procedure are the result of the quantity injected and not conditioned by the purity of the agent is shown by the findings recorded in

the second column of the table, where it is seen that the distinctly irritating commercial penicillin gives concentrations somewhat similar to those of pure penicillin. The results in the last column suggest that when adrenaline is added to pure penicillin considerably higher levels are reached in the aqueous. (The penicillin was dissolved in 0.25 ml. of water to which 0.25 ml. of adrenaline 1:1,000 was added.)

That at least some of the penicillin in the aqueous reaches it through the blood stream rather than directly by penetrating

A.—In rabbits receiving 25,000 units pure penicillin subconjunctivally in one eye and 25,000 units commercial penicillin in the other. B.—In rabbits after 25,000 units pure penicillin subconjunctivally in one eye only. C.—In rabbits after 25,000 units pure penicillin subconjunctivally in one eye only.

* 25,000 units pure penicillin subconjunctivally in each eye with adrenaline.

tion into the blood stream is rapid and that excretion is, too. Aqueous levels seem to be maintained longer than blood levels. The rapid absorption into the blood stream may explain why unmedicated subconjunctival injections of penicillin are less effective than injections with adrenaline; presumably the adrenaline subconjunctivally impedes absorption into the blood stream.

Concentration in Other Ocular Tissues on Application of Ointment and on Subconjunctival Injection.—No systematic study was undertaken, but the results shown in Table V indicate that adequate therapeutic levels are present in the cornea, sclera, and vitreous as late as 5 hours after a subconjunctival injection, and suggest that equally satisfactory results can be achieved by the application of ointments

TABLE V.—Levels of Penicillin reached in Ocular Tissues on Application of Ointment and on Subconjunctival Injection of Pure Penicillin

* Arterial blood at 3 hours showed no penicillin.

† An experimental error of 0.1 unit/ml. was shown by the presence of that amount of penicillin in washings from the eye after washing with 6 ml. saline hours following application of ointment. (Before this estimate was earned at the eye had been washed in two changes of saline.)

Chart II). A copious flow of tears noted in one rabbit 4 hours after instilling ointment, 100,000 units per gramme, revealed a concentration of penicillin of more than 16 units per ml. of tears.

Concentration in Aqueous and Vitreous in Infected Eyes after subconjunctival Injection.—In the course of therapeutic experiments, recorded below, the level of the aqueous and vitreous in infected and treated eyes was determined at 5 hours and 4 hours after subconjunctival injection of 20,000 units with adrenaline. As can be seen from the second column of Table XIV, the aqueous at both 5 and 24 hours contained more than 2 units of penicillin, while the vitreous contained 1 and 0.25 unit respectively. Column 1 of the same table suggests that without adrenaline the values are not dissimilar.

Local Therapy with Pure Penicillin in Intraocular Infections

Two types of experimental infection and two modes of treatment—(a) subconjunctival injections and (b) the application of ointment—were studied. The anterior chamber was infected in 4 eyes and the vitreous in 16. In no case were both the anterior chamber and the vitreous infected. Treatment was begun within two hours after infection.

Anterior Chamber Infection.—(a) Three eyes were infected with suspensions of *Str. haemolyticus* and one with *Staph. aureus*, the suspensions containing 25,000,000 organisms per ml.; 0.1 ml. was injected into the anterior chamber by subconjunctival puncture at the limbus. Treatment consisted of subconjunctival injection of 25,000 units of pure penicillin twice daily for two days. As can be seen from Table VI, the process was controlled, but not completely; in two eyes there was still slight exudate along the pupillary margin on the fifth day, while one eye showed a more severe reaction,

CHART II.—Penicillin levels in ocular tissues of rabbits after local application of ointment (50,000 units/g.).

and the fourth one a still heavier disturbance. These results were, however, better than the state of two untreated eyes, which were largely disorganized. Four further eyes infected less heavily with staphylococcus (1,000,000 organisms per ml.) and treated for a day longer did distinctly better. Only one eye showed exudate along the pupillary margin on the fifth day, while the remaining three were normal. Two untreated control eyes were disorganized by this time.

16	" ..	"	"	"	

(b) Ointment (petroleum jelly and liquid paraffin base) was delivered into the conjunctival sac by a syringe three times daily for three days; the concentration of the ointment was 25,000 units/g. in two eyes, 50,000 in two more, and 100,000 in yet another two. The type and degree of infection were the same as with the second series treated with subconjunctival injection (0.1 ml. of a suspension containing 1,000,000 *Staph. aureus* per ml.), and the results were substantially the same. Five of the six eyes were normal on the fifth day, and one showed a slight exudate at the pupil margin. An untreated control eye was lost.

Vitreous Infection.—(a) Ten eyes were infected with *Staph. aureus* injected centrally into the vitreous by direct puncture at the equator: 0.1 ml. was injected in all cases, the concentration of the infecting fluid being 1,000,000 organisms per ml. in four eyes and 10,000,000 per ml. in the remaining six. Treatment was given twice daily for three days, and, as can be seen from Table VII, the results were remarkably good. Residual vitreous opacities were observed ophthalmoscopically in five of the ten eyes. The four control eyes were all lost.

(b) Six eyes were infected as for subconjunctival therapy, the concentration of the infecting fluid being 1,000,000 *Staph. aureus* per ml. Two eyes were treated with ointment 25,000 units/g. three times daily for three days, two with 50,000 units/g., and two more with 100,000 units. There was no evidence of active inflammation on the fifth day, but the vitreous was largely an organized grey mass. An untreated control eye was lost.

Comparative Experimental Studies on Massive Systemic Administration of Commercial Penicillin

Struble and Bellows (1944) have indicated that a concentration of 1 unit of penicillin per ml. of aqueous can be obtained if 12,800 units per kilo body weight are injected intravenously in the dog—a dose of the order of about 40 times that of the usual clinical dose in man. Town and Hunt (1946) and Town, Frisbe, and Wisda (1946) have extended these observations, and have shown that anterior-chamber infection in the rabbit can be controlled by injections of 5,000 units per kilo body weight intramuscularly at 3-hourly intervals. In confirming and extending these findings an attempt was made to assess the relative value of systemic and subconjunctival administration of penicillin. Commercial penicillin was used for systemic injections.

Concentration in Interior of Eye

In the Primary Aqueous (Chart I).—The level of penicillin in the primary aqueous was determined at different time intervals from 1/4 to 6 hours on intramuscular and intravenous injection of 25,000 and 50,000 units into rabbits. As can be seen from Table VIII an adequate therapeutic level can be

reached in the aqueous by systemic injections of both 50,000 and 25,000 units, but it does not persist for longer than 3 hours. This is a shorter period than that obtained by subconjunctival injection—and incidentally at a lower level, too. In attempts to raise the aqueous level and to increase its duration several modifications of intramuscular injection were tried. The detailed results are given in Table IX.

When an equal quantity of adrenaline 1:1,000 was added to the solution of penicillin (of which 40,000 units were injected) no marked increase in level or persistence was obtained; nor were better results achieved with penicillin to which had been added hexamine (7%) in the hope that this might cause a more ready passage of penicillin into the aqueous. The results were likewise negative when adrenaline (0.5 ml. of 1:1,000) was injected subconjunctivally at the time the intramuscular injection was given. Better results were recorded when penicillin was given intramuscularly in beeswax. The eighteen readings obtained with this mode of administration suggest that low aqueous levels are reached and maintained for at least 6 hours. None the less it is clear from a comparison of Table II with Tables VIII and IX that when approximately equal quantities are injected the subconjunctival route gives higher and more sustained aqueous levels of penicillin. That aqueous levels reached by the injection of penicillin intramuscularly and intravenously are unlikely to be maintained after 3 hours or so is indicated by the level reached in the arterial blood by these methods of administration, and by all the modifications indicated except that in which beeswax was employed (Tables X and XI). With penicillin intramuscularly or intravenously

the blood level is low within 2 hours, and this was substantially uninfluenced by all modifications except beeswax. With penicillin in beeswax injected intramuscularly a high arterial level was still present at 6 hours, and at 22 hours the two of the three readings obtained were still significantly high.

Concentration in Other Ocular Tissues (Chart III).—The level of penicillin in various ocular tissues was determined in one case 30 minutes after the intravenous injection of 50,000 units, and in a second case 2 1/2 hours after an intravenous injection of 25,000 units (Table XII). These determinations indicate that penicillin administered in massive doses reaches in therapeutic levels all the tissues of the globe, the lens excepted.

Concentration in the Vitreous after Modified Intramuscular Injections.—As with the aqueous and arterial blood levels, there is nothing in the few findings available to suggest that any modification substantially affects the level of concentration in

CHART III.—Showing distribution of penicillin in the tissues of the eyes of rabbits after intravenous injections of 50,000 and 25,000 units respectively.

the vitreous (Table XIII). Judging by the two readings recorded this would apply to beeswax-penicillin, too. (The one method that gave a high and sustained vitreous level was the injection of beeswax-penicillin subconjunctivally—a procedure that is

clinically inapplicable, as it produces a severe reaction with gross corneal damage.)

Levels in the Aqueous and Vitreous of Infected Eyes.—As with subconjunctival penicillin, the level of the aqueous and vitreous of infected and treated eyes was determined at 5 hours and at 24 hours after intramuscular administration of 40,000 units in beeswax (Table XIV). The aqueous levels were low and the vitreous levels rather higher.

Treatment of Intraocular Infection by Intramuscular Injections of Massive Doses

Anterior Chamber Infection.—Two eyes were infected with *Str. haemolyticus* and two with *Staph. aureus*, 0.1 ml. of suspensions containing 25,000,000 organisms per ml. being injected into the anterior chamber, as in the experiments with subconjunctival penicillin therapy. Treatment consisted of intramuscular injection of 50,000 units of commercial penicillin twice daily for two days. As can be seen from Table XV, only one of these eyes became

TABLE XV.—Infections of Anterior Chamber: Treatment by Intramuscular Injection

completely normal by the fifth day; in one eye there was minimal reaction, as shown by exudate along the free margin of the iris, while in another there was considerably more exudate. One eye showed the classical picture of panophthalmitis. The two untreated control eyes ended in a destructive suppurative reaction. Four further eyes infected less heavily with *Staph. aureus* (1,000,000 organisms per ml.) were treated in a modified manner, two being given 40,000 units in beeswax twice daily for three days, and two receiving 20,000 units in beeswax subconjunctivally twice on the first day, and 40,000 units in beeswax intramuscularly for two more days. These did distinctly better. The infection in the anterior chamber was completely controlled, but in the two eyes that received beeswax subconjunctivally there was much reaction from the beeswax. Two untreated control eyes were completely lost.

Vitreous Infection.—Ten eyes were infected with *Staph. aureus* by the same technique as used in the therapeutic experiments with penicillin subconjunctivally. Four eyes received 0.1 ml. of suspension containing 1,000,000 organisms per ml., while six eyes had a concentration of 10,000,000 organisms per ml. Treatment consisted of penicillin in beeswax 40,000 units twice daily for three days, and, as can be seen from Table XVI, the infection was controlled in seven of the ten eyes, but in all the eyes there was considerable disorganization of the vitreous. Though the infection could be regarded as largely controlled, these eyes could not be considered as giving a clinically satisfactory result.

Discussion on Experimental Results

The comparative aqueous levels reached by the use of pure penicillin in the form of ointments or of subconjunctival injections, and by commercial penicillin in massive systemic administration, suggest that the best results are likely to be obtained by subconjunctival injection—a conclusion that stands in spite of individual variations in the experimental animal. Moreover, high aqueous levels persist longer with subconjunctival injections than with the other two methods. The advantages of subconjunctival injection are borne out by the experimental results with infections of the anterior chamber and vitreous. Such infections respond well to subconjunctival therapy in doses of 25,000 units/ml. administered twice daily for three days. In contrast, vitreous infections, though controlled, hardly give clinically satisfactory results when treated either by ointment in the conjunctival sac or by massive systemic injections—at any rate in the dosage employed so far. It would appear that the two factors that put both local application of ointment and systemic administration at a disadvantage are lower initial penicillin levels intraocularly and the evanescent character of these levels. On the evidence available the addition of adrenaline to the subconjunctival penicillin injection would seem to be an advantage, but this requires clarification. For the moment it would seem that while pure penicillin applied locally, either as an ointment or as a subconjunctival injection, is a highly efficacious agent, and systemic administration in massive doses a most useful procedure, the balance of advantages in severe intraocular infections rests with subconjunctival injection with adrenaline and massive systemic administration.

Of these two procedures subconjunctival injection, though it has clinical disadvantages, would seem to be preferable. Apart from the fact that the experimental results indicate that in vitreous infections subconjunctival injection is the only promising procedure, it must be borne in mind that the animal results cannot be applied mechanically to man. In experiments on rabbits, largely identical doses were used either as subconjunctival injections or intramuscularly. Translated into terms of its application to man an intramuscular dose will have to be many times that of the subconjunctival dose. Clinically the question is, not whether a given dose should be injected subconjunctivally or intramuscularly, but whether a dose of 25,000 units of pure penicillin be given subconjunctivally or about fifteen times that amount intramuscularly. Even so it must be emphasized that the advantage, as judged by aqueous level and effect on experimental infections, lies with the smaller dose injected subconjunctivally. It is, however, possible that ultimately the frequent application of concentrated ointments may prove an adequate procedure.

The aqueous level in man after massive subconjunctival injection of pure penicillin has not yet been determined. There is therefore no evidence that the pharmacological and therapeutic experiments recorded here for the rabbit apply to man; but there is some indirect indication that essentially this

is the case. In four patients who received 50,000 units of pure penicillin subconjunctivally the blood level was determined at hourly intervals between the first and tenth hours. Two patients had adrenaline together with the penicillin. As can be seen from Table XVII, the blood levels were not dissimilar from those obtained in the rabbit (see Table IV). Moreover, the patients receiving adrenaline showed a more consistent blood level, indicating that the penicillin was being absorbed only slowly into the blood stream. Presumably there was also slow absorption into the aqueous, allowing such level as may be reached in the aqueous to be more persistent. The similarity in this respect makes one hopeful that the pharmacological and therapeutic results seen in the rabbit apply to man.

TABLE XVII.—*Subconjunctival Injection of Pure Penicillin in Man: Blood Levels (Units/ml.) reached after 50,000 Units Injected Subconjunctivally*

	Penicillin Only		Penicillin with Adrenaline	
	First Patient	Second Patient	First Patient	Second Patient
At 1 hour ..	1	0.5	1	2
" 2 hours ..	0.125	0.125	1	0.25
" 3 " ..	Not tested	0	1	0.125
" 4 " ..	0.03	0.125	1	Not tested
" 5 " ..	0.1	0.125	1	0.25
" 6 " ..	0.25	0	1	0.125
" 7 " ..	0.03	0	0.25	0
" 8 " ..	0.06	0	0.125	0
" 9 " ..	0.06	0	0.5	0
" 10 " ..	0	0	0.5	0
" 23 " ..	0	0	0	0

In the light of the experimental results it was felt that clinical trials with ointment of pure penicillin in high concentration and with subconjunctival injections both with and without adrenaline, were justifiable, as was the use of commercial penicillin in massive doses in watery solution, or preferably in beeswax, injected intramuscularly.

Clinical Experiences

Pure Penicillin in External Infections

Adequate control of external infections of the eye by tolerated concentrations of commercial penicillin is readily obtained. The use of pure penicillin might conceivably give better results and avoid the occasional occurrence of irritation. These are possibilities that have not been explored to any extent, and the results so far obtained can be summarized briefly and are essentially observations on tolerance.

Ointments.—In five patients with acute conjunctivitis and in six children with blepharitis ointments containing up to 8,000 units of pure penicillin per gramme were well tolerated and effective. When instilled into the conjunctival sac some ointment could still be seen after an hour. There was no tangible difference whether "eucerin" L.M. base or petroleum jelly and liquid paraffin (90 and 10 parts of each respectively) was used. In subsequent trials only the latter base was used.

The tolerance of the eye to ointments containing 25,000, 50,000, and 100,000 units/g. was established by the successful use of such ointments in three cases of hypopyon ulcer, the ointment being instilled at hourly intervals during the first day and at two-hourly intervals subsequently. Tolerance to ointment containing 100,000 units/g. was also noted in infants with ophthalmia neonatorum (but an adequate clinical result could not be obtained, as the treatment of ophthalmia neonatorum by ointments is unsatisfactory, the ointment being difficult to apply when the lids are swollen, and it is, moreover, squeezed out of the conjunctival sac by the spasmodic contraction of the infant's lids).

Solutions and Suspensions.—Watery solutions of pure penicillin 10,000 units/ml. were used satisfactorily in the form of drops in three cases of acute conjunctivitis. Two drops instilled six times at five-minute intervals and subsequently six times at half-hourly intervals were well borne. In six cases of ophthalmia neonatorum concentrations of 10,000 and 12,000 units in methyl cellulose solution (2%, in a buffered aqueous medium) used in the same manner were likewise well tolerated, as was the use in four further cases of a suspension of pure penicillin in oil (castor oil or liquid paraffin) in a concentration of 10,000

units/ml. A suspension of pure penicillin in castor oil (10,000 units/ml.) instilled at hourly intervals for five days proved efficacious in a case of hypopyon ulcer.

Pure Penicillin In Intraocular Infections

The opportunity of studying the value of pure penicillin in eight cases of post-operative infection presented itself by the kind co-operation of colleagues, and the following remarks are based on their reports.

1. In a case of infection after cataract extraction in a diabetic patient one subconjunctival injection of 25,000 units was given on the seventh day after the infection had become established. There was no tangible improvement on the following day, and the eye was excised.

2. In another case of infection after cataract extraction subconjunctival injections of 50,000 units of pure penicillin were given on the sixth and seventh days after the onset of infection, combined with five doses of 100,000 units of commercial penicillin intramuscularly at 12-hourly intervals. There was considerable improvement, but some relapse on the ninth day, when the course was repeated. The infection was clinically controlled, but the eye now shows evidence of early shrinking. A course of sulphamezathine was given without result between the third and sixth days (before penicillin treatment).

3. In this case infection was noted at the first dressing 24 hours after a cataract extraction, and consisted of a localized exudate in the anterior chamber at the temporal side of the corneal incision. Powder of commercial penicillin (about 30,000 units) was sprinkled on the wound, and the procedure was repeated later in the day and again on the following morning, a total of 100,000 units being used. There was a distinct improvement, but the infection still persisted. Sixty hours after the operation a subconjunctival injection of 50,000 units of pure penicillin was given, and the following morning (72 hours after operation) the infection appeared under control, so that further treatment was suspended. Forty-eight hours later there was a relapse; two subconjunctival injections were given, with definite improvement by the following day, when two further injections were made, and one more the day after. Recovery since has been steady and uninterrupted.

4. In a further case of infection after cataract extraction treatment was begun after five days, and consisted in opening the anterior chamber and irrigating with 10 ml. solution of pure penicillin containing a total of 100,000 units. This was repeated on four subsequent days. The infection was checked, and though the eye is likely to be retained it is unlikely to have any useful vision. An organized mass of exudate is still present in the anterior chamber after 14 days. (A subsequent report suggests that after capsulectomy useful vision is likely to be present.)

5. A fully developed panophthalmitis was observed in a patient three years after a trephine operation for a glaucoma. Treatment consisted of drops of commercial penicillin 2,000 units/ml. at half-hourly intervals, with considerable improvement after 24 hours, when the cornea was clearer and a purulent infiltration of the vitreous could be seen. Treatment was continued for two more days without much result. Intramuscular injection of 100,000 units of commercial penicillin was then instituted at 3-hourly intervals for 72 hours, resulting in further control of the infection in the anterior chamber but not of that in the vitreous. Daily injection of 50,000 units of pure penicillin subconjunctivally was begun 14 days after the patient first came under observation, and continued for 4 days. This led to the vitreous becoming less dense, and its reflex, as seen by oblique illumination, less yellow and more greyish; but the eye must be regarded as functionally lost.

6. In a further case of post-operative infection a simple extraction of a hypermature cataract had been performed with loss of fluid vitreous at the operation. The patient was a diabetic. At the first dressing, 24 hours later, slight mucoid discharge was seen, and penicillin drops 2,500 units/ml. were instilled. Twenty-four hours later a severe infection was fully established: the lids were red and oedematous, chemosis was marked, and there was total hypopyon. A course of sulphamezathine was instituted, penicillin drops 2,500 units/ml. were instilled 2-hourly, and injections of penicillin intramuscularly were begun—two of 50,000 units at intervals of 6 hours and subsequently 25,000 units 3-hourly. During the 3 days this treatment was continued the condition steadily deteriorated, and pus began to exude from the corneal section. Subconjunctival injections of 50,000 units of pure penicillin in 0.5 ml. of 2% "novocain" were then given at 8-hourly intervals, with ointment 100,000 units/g. instilled into the conjunctival sac 2-hourly. After 6 days of this treatment the condition had improved to the extent that the patient was now able to open his eyes, and the infection had become localized to the upper segment of the anterior chamber. The injections were now causing pain, and these as well as the ointment were discontinued, atropine drops and fomentations only being used. Further improvement continued for 12 days, when there was a sudden

worsening. The eye became intensely red and engorged and pus in the vitreous could be seen through the pupil. There was no perception of light. A complete hypopyon rapidly formed and the eye was eviscerated. The vitreous was found to be full of pus.

7. In a case of intracapsular extraction complicated by prolapse of vitreous the iris was muddy at the first dressing three days later. Twenty-four hours later a small hypopyon was present. A course of sulphamerazine was instituted and ointment of pure penicillin 50,000 units/g. instilled into the conjunctival sac 2-hourly. In spite of treatment continued for 3 days the hypopyon increased, and the patient showed intolerance to the sulphonamide. Treatment, apart from atropine drops, was changed to subconjunctival injections of 50,000 units of pure penicillin in 0.5 ml. of 2% novocain at 6-hourly intervals. After eight injections the hypopyon had disappeared; the eye was almost white but showed post-operative iridic adhesions. Though the eye was saved, the ultimate outcome as regards vision is still uncertain.

8. A man aged 58 had undergone a second operation for retinal detachment by surface coagulation and three micropunctures. Ophthalmic catgut was used for re-attaching the external rectus severed during the operation, and an intraglottal injection of 50,000 units penicillin in oil was given prophylactically. At the first dressing 48 hours later there was much chemosis, the anterior chamber was deep, and the iris yellowish green. Two further intraglottal injections of 150,000 units of penicillin in oil were given the same day, and full doses of sulphamerazine instituted and continued for 7 days. On the following day the condition was worse, the cornea now being cloudy, and hypopyon was present. Further deterioration occurred during the next 24 hours; the vitreous seen through the remaining area of clear cornea was cloudy. Subconjunctival injections of 50,000 units pure penicillin in 0.5 ml. of 2% novocain with adrenaline were given at 6-hourly intervals, a total of 20 injections being used. Improvement was noted after the sixth injection, and at the end of the course of injections there was no hypopyon, the cornea was clear, and the iris less yellow; the anterior chamber was still deep. General administration of 150,000 units of penicillin in oil was continued daily for 3 days, when all treatment was suspended. On the following day the eye was quiet, the cornea clear, the iris normal in colour, and the anterior chamber almost normal in depth. Eight days later the patient was discharged. The eye is still somewhat red, there was a small hyphaemia, and there appears to be a haemorrhage in the vitreous.

Apart from these eight cases of post-operative infection three cases of infection of the vitreous associated with intraocular foreign body were treated.

1. A man aged 27 sustained a perforating injury of his left eye while using a hammer and chisel. The lens was semi-opaque, the pupil irregular, and there was no red reflex. A foreign body was extracted by the magnet from the vitreous on the same day, and a scleral suture inserted. Convalescence was uneventful for the 5 succeeding days, when suddenly much congestion and chemosis set in. Ointment of pure penicillin 100,000 units/g. was then instilled at 2-hourly intervals for 24 hours, and 50,000 units of pure penicillin in 0.5 ml. of water was injected subconjunctivally and repeated on eight further occasions at 12-hourly intervals. The injections proved painful. After the first two, which did not seem to influence the infection, the wound was explored and the scleral sutures removed, though they did not appear to be infected. In spite of continued treatment the infection progressed, and on the tenth day the eye was eviscerated. The vitreous was found to be a purulent mass. Two hours before evisceration 50,000 units of pure penicillin were injected subconjunctivally, and at evisceration the aqueous and some vitreous were collected for penicillin assay and culture. The penicillin content was found to be 32 units in the aqueous and 0.5 unit in the vitreous. A penicillin-sensitive *Staph. aureus* was present in the vitreous, but there were no organisms in the aqueous.

2. In a man of 21, whose right eye was hit by a small ball-bearing 48 hours previously, hypopyon filling a third of the anterior chamber, and grey opacities in a hazy vitreous, were present when he was first seen. Because of the established infection no immediate attempt at removing the intraocular foreign body was made. Ointment of pure penicillin 100,000 units/g. was instilled at 2-hourly intervals for 3 days, with but little effect. After 14 subconjunctival injections of 50,000 units of penicillin at 6-hourly intervals the infection seemed sufficiently controlled to warrant an attempt at magnet-extraction of the foreign body. There was, however, no response to the magnet. Two days later the infection flared up, and was not controlled by eight subconjunctival injections of 50,000 units. The eye had to be eviscerated, and the vitreous was found to be a purulent mass.

3. While hammering a boiler, three days before admission, a man aged 38 sustained a perforating injury to his right eye. On admission the vitreous was grey and a hypopyon occupying one-third of the anterior chamber was present. X-ray examination showed a foreign body located just outside the globe. A course of sulphamezathine was given unsuccessfully for 3 days, and then suspended for penicillin

therapy. This consisted in the instillation of ointment (100,000 units/g.) 2-hourly by day and 4-hourly at night, and of 20 subconjunctival injections of 50,000 units in 0.5 ml. of 2% novocain solution given at 6-hourly intervals. As a re-location put the foreign body as just inside the globe an attempt at magnet-extraction was made. This, however, proved unsuccessful. The hypopyon disappeared after 3 days' treatment with penicillin, and an organized opacity in the upper part of the vitreous could be seen. This mass has not been influenced by penicillin therapy, and though the treatment seems to have checked the development of panophthalmitis the eye is now shrinking and must be regarded as functionally lost.

Subconjunctival Penicillin In Interstitial Keratitis

Four patients were treated. A girl aged 19 years received twelve subconjunctival injections of 25,000 units in one eye, generally at daily intervals, together with a systemic course of 200,000 units daily for seven days. The injections were well tolerated, though some conjunctival adhesions seemed to form towards the end of the course. The other three patients were soldiers with interstitial keratitis developing apparently as a result of acquired syphilis. In the case of the girl there was rapid and progressive whitening of the eye. Three months later she still had a central corneal haze reducing vision to 6/18; this, however, practically disappeared during the subsequent two months, when vision rose to 6/9. Two of the men responded well to four and six subconjunctival injections of 25,000 units, vision rapidly becoming normal, though they had shown no response to classical local and antisyphilitic treatment. In the third man the response was poor.

Subconjunctival Penicillin In Hypopyon Keratitis

In addition to the three cases of hypopyon ulcer treated successfully with ointments of pure penicillin and one by penicillin in oily suspension there were five others treated by subconjunctival injection.

The first case was that of a man aged 68, who initially responded to pure penicillin ointment (100,000 units/g.) applied hourly for 12 hours. Three days later there was a sudden and severe relapse, the anterior chamber showing a total hypopyon within 24 hours. At this stage two subconjunctival injections of 25,000 units at intervals of 24 hours failed to influence the condition, the eye showing evidence of panophthalmitis. On admission the conjunctival swab had shown *Staph. aureus* microscopically, and culture revealed *Ps. pyocyanea* (? a contaminant). Unfortunately no swab was taken of the contents of the anterior chamber when the eye was ultimately eviscerated.

In a second patient, a lady aged 83, initially more severely affected than the man with a hypopyon of five days' standing, the outcome was more favourable. Hourly instillation of pure penicillin in a suspension of castor oil (10,000 units/ml.) led to rapid improvement within 15 hours. As the cornea was still hazy, some hypopyon still present, and the general condition poor (the patient had a large carbuncle on the nose), two subconjunctival injections of 50,000 units with adrenaline were given at 12-hourly intervals. The eye was now normal in appearance, and penicillin in oil (10,000 units/ml.) was continued for a further 48 hours.

In a third patient, with hypopyon filling half the anterior chamber, pure penicillin in ointment form (25,000 units/g.) was applied at 2-hourly intervals for 48 hours with no marked improvement. One injection of 50,000 units with adrenaline was then given subconjunctivally, and the hypopyon diminished considerably. A second subconjunctival injection was given after 48 hours. Three days later the anterior chamber was clear. Application of ointment at 2-hourly intervals was continued throughout.

In a further case of hypopyon complicating an old-established iridocyclitis with secondary cataract and a tension of +3, treatment with atropine and penicillin drops 500 units/ml. at 3-hourly intervals for 5 days broke down some iris adhesions but did not affect the hypopyon or tension. Subconjunctival injections of 50,000 units of pure penicillin were now given on three occasions on alternate days, while ointment of pure penicillin 100,000 units/g. was instilled 3-hourly during the first 4 days. On the sixth day the hypopyon had become barely visible as a mere crescent. Further treatment by short-wave therapy brought the tension down to normal.

In a case of recurrent hypopyon iritis associated with rheumatoid arthritis, treatment for 12 days with ointment of commercial penicillin 800 units/g. gave no response. There was some improvement after subconjunctival injection of 50,000 units of pure penicillin daily for 3 days, and resolution after 14 days' treatment with penicillin ointment 100,000 units/g. instilled 2-hourly. The end-result was excellent, but it is doubtful whether penicillin treatment contributed to it.

Discussion

The studies recorded here indicate that pure penicillin is remarkably well tolerated by the eye, and that dosage need no longer be limited by the intolerance of the eye to the impure supplies available till recently. There seems to be no upper limit of concentration of drops and ointments of penicillin that can be instilled into the conjunctival sac, while massive amounts can be given subconjunctivally. It is also clear that ointments in high concentration instilled into the conjunctival sac allow adequate penetration into the anterior chamber of the eye. This applies still more to subconjunctival injections, so that the current teaching that adequate therapeutic levels cannot be obtained in the interior of the eye is no longer valid. It is also established that adequate levels of penicillin can be obtained by massive systemic administration. The results of biological assay are confirmed by the experiments in infection of the interior of the eye, for infections of the anterior chamber respond to instillation of concentrated ointments, to systemic administration of massive doses, and to subconjunctival injections. Infections of the vitreous are, however, only partially controlled by systemic administration and by the application of ointments, and subconjunctival injections appear to be the only satisfactory method of treating vitreous infections.

The clinical use of penicillin in intraocular infections still requires clarification. The range of efficacy of ointments for intraocular infections has still to be established, as has the frequency of application. Experimental findings suggest that adrenaline should be used together with pure penicillin for subconjunctival injections, but it remains for clinical trial to establish whether this is necessary or desirable, as also whether 2% novocain solution should replace water as a solvent for the penicillin in such patients who do not tolerate injections of 50,000 units subconjunctivally. Likewise clinical trial will have to establish the best way of giving massive doses of penicillin systemically—whether in aqueous solution or in oily suspension in beeswax. In intraocular infections involvement of the vitreous is always a grave complication. The experimental results recorded here indicate that even a low-grade infection has serious implications, possibly because of the disorganization of the vitreous consequent on physical alterations of its colloidal state. Only the most effective measures against bacterial action are therefore likely to be clinically efficient.

The limited clinical data recorded here bring out forcibly three essential points in penicillin treatment of intraocular infections. In the first place, early treatment is essential; little is to be expected once there is extensive disorganization of the eye from the suppurative reaction. Secondly, it is important to continue treatment for at least 24 hours, and possibly as long as 72 hours, after the eye is apparently normal, as otherwise residual infection may readily flare up—a point that is well appreciated in the treatment of ophthalmia neonatorum. Thirdly, in infection of the anterior chamber evacuation and irrigation at an early stage, supplementary to subconjunctival injections, may prove advisable, but it is clear that little can be expected from irrigation by itself, with its momentary antibacterial effect. The considerable amount of work that has been done on sustaining adequate levels of concentration of penicillin is in itself a strong indication against irrigation as a sole method of treatment.

The adequate use of pure penicillin for intraocular infections promises control of a hitherto uncontrollable condition, but the optimum modes of use have still to be established. At the moment the most promising approach would seem to lie with subconjunctival injections of 50,000 units of pure penicillin at intervals of 6 hours. In the case of vitreous infections it may prove necessary to combine subconjunctival with massive systemic injections, and possibly even direct intravitreal injection of pure penicillin.

Summary

Pure penicillin is well tolerated by the eye when applied locally in ointments containing up to 100,000 units per gramme or in watery solutions. Intravitreal injection of pure penicillin, though not free from secondary effects, is also well tolerated. Repeated subconjunctival injections of 50,000 units in 0.5 ml. of water are well tolerated.

Adequate therapeutic levels of penicillin can be obtained in the aqueous by the installation of concentrated ointments into the conjunctival sac. Higher and more persistent levels are secured by subconjunctival injections. Adequate though rather more evanescent levels are obtained by the systemic administration of penicillin in massive doses. When subconjunctival injections are used the addition of adrenaline increases persistence; intramuscular injection of penicillin in beeswax also gives more sustained levels.

Experimental infections of the anterior chamber are readily controlled by the use of concentrated ointments, subconjunctival injections, and systemic administration of penicillin. In vitreous infections subconjunctival injection is the only procedure that was found satisfactory; no more than partial control is obtained by other methods.

Preliminary clinical trials indicate that the experimental results are largely applicable to man.

We are indebted to Miss J. M. Dollar, and to Messrs. A. J. Cameron, R. P. Crick, L. M. Green, M. Klein, H. C. Kodilinye, B. W. Rycroft, L. H. Savin, E. Shoen Sack, A. F. L. Shields, T. M. Tyrrell, and T. H. Whittington, for help with clinical material. To Mr. B. Helliwell and Mrs. I. Moncrieff we are obliged for technical assistance. We are also obliged to Dr. H. M. Walker, O.B.E., of Glaxo Laboratories, for facilities and advice, and to Mr. J. T. Marsh, M.P.S., and Mr. W. A. Woodard, M.P.S., for kindly supplying various preparations of penicillin. To the resident medical staff of the Royal Eye Hospital—Drs. Joan Haythorne, Joan Jenkins, Mary Savory, J. Kennedy, R. E. O'Neal, and K. B. Redmond—we are indebted for their help in the treatment of patients, as also to Sisters Condon and Young of White Oak (L.C.C.) Hospital, and Sisters Hollands and Thorogood of the Ophthalmic Unit at Lambeth (L.C.C.) Hospital.

PENICILLIN IN TREATMENT OF ACUTE PUERPERAL MASTITIS

BY

MARY D. TAYLOR, M.B., B.S.

Paediatric Registrar, Princess Mary Maternity Hospital

AND

STANLEY WAY, M.R.C.O.G.

Temporary Assistant to the Department of Obstetrics and
Gynaecology, Royal Victoria Infirmary, Newcastle-upon-Tyne

Since penicillin is now universally available, and especially as it has come to our notice that some clinicians are dissatisfied with its effect in acute puerperal mastitis, a short communication on our own somewhat limited experience would seem appropriate, and might serve as an encouragement for a further trial of our suggested technique. Theoretically, since the predominant causal organism in infection of the breast is *Staphylococcus aureus*, penicillin should prove effective. It appears to us that the unsatisfactory results of which we have heard have been due to (a) the use of local therapy only, or (b) underdosage. Vaughan Hudson (1944) found that local penicillin alone was not successful in acute soft-tissue infections unless they were entirely confined to the surface, and this is not the case by the time a diagnosis of acute puerperal mastitis is made. More recently Hodgkinson and Nelson (1945) have reported from the United States on 24 cases of acute puerperal mastitis successfully treated with large doses of penicillin administered systemically.

The principles underlying the treatment of this disease are, first, emptying of the breast, and, secondly, adequate control of the infection. The first principle may be attained by suppressing lactation by means of oestrogens, or by regular emptying with a breast pump, or by allowing the infant to suckle. We prefer to keep the breast empty by permitting the child to feed, but if the discomfort caused to the patient is very great then we temporarily discontinue suckling and give a small dose of stilboestrol (usually not more than 1 mg. in 24 hours). Adequate control of the infection can, in our opinion, be attained only by the systemic administration of

large doses of penicillin. We administer it by 3-hourly intramuscular injections of 12,000 to 20,000 Oxford units.

Our criteria for starting treatment are pyrexia, associated with flushing, and hardening of the breast; but from some of our cases it appears that pyrexia with pain in the breast, even though there are no other changes, should be considered an indication for treatment.

Results

Case 1.—Primipara, aged 23. 6/11/45: Manual rotation and forceps delivery on account of persistent occipito-posterior presentation. Breast-feeding started. 14/11/45: Severe pain in the left breast on suckling. 15/11/45: T. 102° F. (38.9° C.); P. 100. Hard inflamed area in outer and upper quadrant of the left breast. Suckling very painful. Breast rested for 12 hours and emptied with pump. Penicillin started. Stilboestrol 0.5 mg. 16/11/45: T. 100° F. (37.8° C.). 17/11/45: T. 99.6° F. (37.55° C.). Breast fluctuating. 18/11/45: T. 99.4° F. (37.4° C.). Abscess aspirated and 25 ml. of pus obtained. 19/11/45: T. 98.4° F. (36.9° C.); P. 90. Aspiration again produced pus. No pain. Flush gone. 20/11/45: T. 98.2° F. (36.8° C.); P. 82. No pain. No pus obtained. Slight thickening at site of abscess. 21/11/45: T. 98.2° F. (36.8° C.); P. 72. Breast appears normal. Lactating well. 22/11/45: Penicillin discontinued. Total dosage, 1,050,000 Oxford units.

Case 2.—Primipara, aged 33. 3/11/45: Normal delivery. Breast-feeding begun. 14/11/45: Flushed left breast. T. 99° F. (37.2° C.); P. 100. 15/11/45: T. 102° F. (38.9° C.); P. 116. Suckling stopped for 12 hours. Stilboestrol 0.5 mg. Penicillin started. 16/11/45: T. 100° F. (37.8° C.); P. 116. Flush diminished. Less pain. Baby suckling. 17/11/45: T. 98° F. (36.7° C.); P. 96. 18/11/45: T. 98° F. (36.7° C.); P. 90. Breast normal. 20/11/45: T. 98° F. (36.7° C.); P. 80. Penicillin discontinued. Total dosage, 525,000 Oxford units.

Case 3.—Primipara, aged 21. 6/4/46: Normal delivery. Breast-feeding started. 16/4/46: Baby developed a septic finger, which was treated with penicillin. Breast-feeding continued. 20/4/46: Baby recovered. Mother's temperature, 101° F. (38.3° C.); P. 100. Flushed left breast. Penicillin begun. Breast-feeding continued. 21/4/46: T. 103.8° F. (39.9° C.); P. 126. 23/4/46: T. 98° F. (36.7° C.); P. 80. Little pain, definite thickening and hardness inner and lower quadrant of left breast. 24/4/46: T. 98° F. (36.7° C.); P. 82. No flush. Thickening resolving. 25/4/46: T. 98° F. (36.7° C.); P. 82. Thickening almost completely resolved. 26/4/46: Breast normal. Penicillin discontinued. Total dosage, 600,000 Oxford units.

Case 4.—Para-2, aged 20. 8/4/46: Normal delivery. Breast-feeding started. 17/4/46: T. 101.2° F. (38.4° C.); P. 100. Flushing and thickening of the left breast. Penicillin begun. 18/4/46: T. 98.6° F. (37° C.); P. 104. 19/4/46: T. 100.8° F. (38.2° C.); P. 104. 20/4/46: T. 98° F. (36.7° C.); P. 90. Breast normal. 22/4/46: T. 98° F. (36.7° C.); P. 90. Penicillin discontinued. Total dosage, 600,000 Oxford units.

Case 5.—Primipara, aged 21. 20/4/46: Normal delivery. Breast-feeding started. 26/4/46: Cracked nipples. Breast rested for 12 hours. 27/4/46: T. 102° F. (38.9° C.); P. 130. No abnormality found on examining breasts. 28/4/46: T. 103° F. (39.4° C.); P. 130. Definite thickening and tenderness outer and upper quadrant of left breast. Penicillin begun. 29/4/46: T. 99.4° F. (37.4° C.); P. 96. Breast flushed and thickened. 30/4/46: T. 98° F. (36.7° C.); P. 98. Flush less. Thickened area considerably smaller. 1/5/46: T. 98° F. (36.7° C.); P. 90. No flush. 2/5/46: T. 98° F. (36.7° C.); P. 90. Breast normal. 4/5/46: T. 98° F. (36.7° C.); P. 80. Penicillin discontinued. Total dosage, 700,000 Oxford units.

Case 6.—Para-2, aged 26. 28/4/46: Normal delivery. Breast-feeding begun. Owing to shortage of beds this patient was transferred to the district on the third day of the puerperium. She herself attempted to discontinue breast-feeding on the tenth day and developed acute puerperal mastitis. 12/5/46: Readmitted to hospital. T. 100° F. (37.8° C.); P. 106. Tender flushed left breast. Thickened area 2 in. (5 cm.) in diameter in upper and outer quadrant. Penicillin started. Baby put back on breast and all artificial feeding stopped. 13/5/46: T. 100° F. (37.8° C.); P. 104. Breast flush limited to upper and outer quadrant. Tenderness also limited to this area. 14/5/46: T. 100° F. (37.8° C.); P. 83. Thickening now 1 in. (2.5 cm.) in diameter. Slight flush. Slight tenderness. 15/5/46: T. 97.8° F. (36.55° C.); P. 64. No flush. Slight thickening. 16/5/46: T. 98° F. (36.7° C.); P. 80. No thickening, flush, or tenderness. Penicillin discontinued. Total dosage, 500,000 Oxford units. Two weeks later this patient returned to the clinic. She was still lactating freely, but the baby was again being artificially fed. She was instructed to re-establish breast-feeding, but has since refused to return to clinic.

Case 7.—Para-3, aged 30. 29/4/46: Normal delivery. 5/5/46: Cracked nipples. Breast rested for 12 hours. 7/5/46: T. 101.8° F. (38.8° C.); P. 100. Right breast very flushed and tender. Penicillin started. 8/5/46: T. 98.4° F. (36.9° C.); P. 88. 9/5/46:

T. 98° F. (36.7° C.); P. 82. 10/5/46: T. 97° F. (36.1° C.); P. 80. Breasts normal. Penicillin discontinued. Total dosage, 300,000 Oxford units.

Case 8.—Primipara, aged 25. Delivered at another hospital and admitted 9/5/46 on account of an infected perineal laceration, for which she was being treated with sulphamezathine. The baby was not admitted. 10/5/46: T. 100° F. (37.8° C.); P. 100. Tender flushed left breast. Lactation suppressed with stilboestrol. Penicillin begun and sulphamezathine discontinued. 11/5/46: T. 100° F. (37.8° C.); P. 104. Slight flush and tenderness over an area the size of a penny. 12/5/46: T. 99.6° F. (37.55° C.); P. 86. Breasts normal. 15/5/46: T. 98° F. (36.7° C.); P. 80. Penicillin discontinued. Total dosage, 500,000 Oxford units.

Case 9.—Para-3, aged 32. 5/6/46: Normal delivery. Breast-feeding begun. 12/6/46: T. 99.6° F. (37.55° C.); P. 90. Outer and lower quadrant of left breast flushed and tender. Penicillin started. 13/6/46: T. 97.6° F. (36.4° C.); P. 88. Flush almost gone. Slight tenderness. 14/6/46: T. 97.3° F. (36.55° C.); P. 86. Breast normal. 18/6/46: T. 97° F. (36.1° C.); P. 80. Penicillin discontinued. Total dosage, 500,000 Oxford units.

Case 10.—Para-2, aged 26. 9/6/46: Normal delivery. Breast-feeding begun. 17/6/46: T. 100° F. (37.8° C.); P. 120. Flush, tenderness, and induration in inner and lower quadrant of right breast. Penicillin started. 18/6/46: T. 98° F. (36.7° C.); P. 110. Severe pain in breast. Stilboestrol 3 mg. As breast-feeding did not increase the pain it was continued. 19/6/46: T. 97° F. (36.1° C.); P. 84. Flush decreased. Localized hardening the size of a walnut. 20/6/46: T. 97.6° F. (36.4° C.); P. 84. Breast normal. 22/6/46: T. 97.6° F. (36.4° C.); P. 72. Penicillin discontinued. Total dosage, 500,000 Oxford units.

Comment

The above constitute the total number of cases of acute puerperal mastitis seen in the Princess Mary Maternity Hospital between November, 1945, and July, 1946, during which time 1,537 deliveries took place. In these cases there was quick resolution, with no prolonged disorganization of the breast; in only one instance did suppuration occur, and this was treated by closed aspiration. Lactation was not interfered with, and breast-feeding was maintained except in Case 8, where the baby was not admitted to hospital. The total period of disability was not longer than 7 days, and discomfort was never present for more than three days. The following table shows the length of time taken to achieve a cure as judged by the disappearance of all signs.

2 cases were cured in 2 days			
4	"	"	3
1	case was	"	4
1	"	"	5
1	"	"	6
1	"	"	7

No baby became infected as a result of the continued suckling. There were no recurrences after the cessation of treatment.

These results are in such great contrast to those of the usual methods that the treatment seems worthy of an extended trial, for it appears that, provided early treatment is instituted, penicillin can abolish the morbidity of this painful and crippling puerperal complication. Our results are in agreement with those of Hodgkinson and Nelson, who suggest that, owing to the ineffectiveness of sulphonamide therapy in this disease, it should be entirely replaced by penicillin.

We wish to thank Dr. Jean Grant and Dr. G. I. Isaacs for their assistance in treating these cases.

Two motion pictures on tuberculosis case-finding with miniature film mass radiography of the chest have just been completed for the U.S. Public Health Service, under the supervision of the Tuberculosis Control Division. The films demonstrate the techniques, the staff, procedures, and equipment required for: (1) routine admission miniature film chest x-ray examination of all patients and personnel entering general hospitals; (2) miniature film mass radiography in community tuberculosis case-finding programmes. These are teaching and orientation films for an audience of professional, technical, or administrative personnel, or trainees, in the fields of medicine, public health, and hospital care. The film prints are 16 mm. size, black and white, with sound. They may be purchased from Castle Films, Inc., 30, Rockefeller Plaza, New York 20, N. Y.: routine admission chest x-ray in general hospitals, \$23.00 per print; techniques of group chest x-ray services, \$21.00 per print.

USE OF "BENADRYL" FOR PENICILLIN URTICARIA

PRELIMINARY REPORT

BY

R. R. WILLCOX, M.B., B.S.

Lieut.-Col., R.A.M.C.; Adviser in Venereology to the War Office

"Benadryl" (β -dimethylaminoethyl benzhydryl ether hydrochloride) is a synthesized chemical compound said to possess both anti-allergic properties and antispasmodic activity capable of relieving spasms of smooth muscle. This antihistamine agent is administered orally in the form of capsules, the dose for an average adult being one capsule (50 mg.) three or four times daily. Its toxic-effects are said to be minimal but include a sensation of drowsiness and nausea. In consequence the simultaneous administration of barbiturates or opium derivatives should be conducted with caution. During the past year this drug has been undergoing extensive trials in the United States of America, and has shown encouraging results as a palliative for urticaria, angioneurotic oedema, serum sickness, and erythema multiforme; while hay-fever and vasomotor rhinitis have also been treated.

One of its uses in the U.S.A., and doubtless soon on this side of the Atlantic too, is the symptomatic treatment of urticaria occurring in patients undergoing penicillin therapy. This condition, which may arise at any time during treatment, often becomes apparent at the end of a 7- or 12-day course in the treatment of syphilis. Generalized urticaria may be associated with oedema of the eyelids, swellings of the ankles or wrists, and effusions into joints, and, when treated symptomatically by means of adrenaline and ephedrine, usually takes 3 to 5 days to subside completely. The frequency of this complication depends to some extent on the particular batch of penicillin used or on the medium in which it is prepared. In America the early penicillin in oil-beeswax mixtures were said to be more liable to cause urticaria than penicillin in aqueous solution. It is therefore likely that this drug will be widely used in this connexion and the preliminary reports from America are most encouraging.

The following describes the action of "benadryl" on six cases of urticaria, five of which were considered to be due to intramuscular penicillin therapy. The penicillin used throughout was manufactured on Feb. 6, 1946, by the Distillers Company, Ltd.; the batch number was 0025.

Case I

A young man of 24, suffering from congenital syphilis with interstitial keratitis. The blood Wassermann was strongly positive and the quantitative Kahn 10 units. The cerebrospinal fluid had a protein value of 80 mg. per 100 ml. and contained a slight excess of globulin, but was otherwise normal. There was no history of previous allergy. In April, 1946, he received 720,000 units of penicillin in 36 three-hourly injections for a septic throat following dental extraction.

Present Attack.—Between Aug. 3 and 3 a.m. on Aug. 16, 1946, he was given a total of 4,600,000 units of penicillin (40,000 units every three hours). Some complaints were made of local pain after these injections. At 10 a.m. on the 17th there was slight urticaria, with a small lesion below the left eye and a larger one on the left flank. When seen again at noon, four more lesions had appeared on the extensor surface of the right forearm. One capsule (50 mg.) of "benadryl" was given i.d. for one day, and by the following morning the urticaria had entirely subsided and there was no recurrence. No untoward reactions were noted. The maximum temperature recorded during the attack was 99° F. (37.2° C.), and a blood count on Aug. 19 showed: W.B.C., 8,500 per c.mm. (polymorphs, 48.5%; lymphocytes, 44%; mononuclears, 4%; eosinophils, 3.5%).

Case II

Male aged 38, with a diagnosis of latent syphilis. This was discovered in August, 1945, when the cerebrospinal fluid was normal but the blood Wassermann was strongly positive and the quantitative Kahn 20 units. Since then, though antisyphilitic treatment had been continuous, at the time of admission the Wassermann was still strongly positive and the quantitative Kahn 2 units. There had been a previous attack of urticaria following an injection of antitetanic serum while in India in 1935. In September, 1945, he received

00,000 units of penicillin over 7½ days without ill effect. This was consolidated with two full courses of neosarsphenamine and muth, which were completed in July, 1946.

Present Attack.—Penicillin therapy was begun on July 26, 1946, in injections of 40,000 units were made every three hours. On July 6, when 3,120,000 units had been administered, generalized urticaria developed involving the back, thighs, wrists, and knees. There was no pyrexia, and a blood count on this day showed the W.B.C. to number 8,800 per c.mm. (polymorphs, 52%; lymphocytes, 45%; mononuclears, 4.5%; eosinophils, 2%; basophils, 0.5%). One capsule (50 mg.) of "benadryl" was then administered orally. By the following day there was some improvement, and the dose was increased to one capsule t.i.d. By the 8th further improvement was evident, there remaining only a few scattered erythematous patches. Three more capsules were given, making a total dosage of 350 mg. over 2½ days, and by the next day the skin was quite clear. While the result was not dramatic, the improvement was steady and maintained. The usual duration of such a severe reaction before improvement is manifest is, in my experience, about 4 days.

Case III

Man aged 29, with a diagnosis of sero-positive primary syphilis. There was no history of allergy or of previous penicillin treatment.

Present Attack.—Between July 17 and 24, 1946, a total of 2,400,000 units of penicillin were administered in conjunction with 10 daily intravenous injections of 0.06 g. of mapharside. The arsenic injections were completed on the 28th, at which time a white cell count showed W.B.C., 8,000 per c.mm. (polymorphs, 61%; lymphocytes, 35%; mononuclears, 4.5%; basophils, 1%). On this day he developed severe generalized urticaria of left thigh, buttocks, and both legs. He was given two doses of adrenaline 10 min. (0.6 ml.) and 1b. ephedrine 1/2 gr. (32 mg.) t.i.d. On the 29th the urticaria was unchanged in severity, and one capsule of "benadryl" (50 mg.) was prescribed t.i.d. By the following morning four capsules (200 mg.) had been taken, but the urticaria was worse, and it was decided to give a further 10 minims of adrenaline in addition. This time the administration had rather alarming results. The patient at once became pallid, developed a rapid thready pulse, and collapsed. As he recovered, his temperature rose within an hour to 101° F. (38.3° C.). A blood count gave the following results: R.B.C., 3,030,000; Hb, 99%; W.B.C., 13,300 (polymorphs, 83.5%; lymphocytes, 13.5%; mononuclears, 2%; basophils, 1%). At this time it was thought that the severe reaction to the adrenaline might in some way be aggravated by the concurrent administration of "benadryl." Both drugs were therefore discontinued.

On the 31st the general condition was much improved, though intense pallor persisted. The urticarial lesions were still pronounced in the thighs and chest, and the temperature was 99° F. (37.2° C.). Ephedrine 1/2 gr. (32 mg.) t.i.d. was then renewed, and by the following day the lesions were subsiding, though the temperature remained at the same level. The patient continued with the ephedrine and by the 8th the skin was normal, but the temperature was still 99° F. He was discharged to duty on Aug. 14.

Case IV

A youth of 18½ with recurrent impetigo; the lesions were on the face and behind the ears. There was no history of previous allergy. In June, 1946, he had been admitted to hospital with impetigo of the face, and was treated with penicillin cream for two weeks. Two weeks after discharge the condition relapsed, and he was readmitted and treated with penicillin cream for a further week. After another week at his unit, a second relapse occurred, and he was admitted to hospital again on Aug. 3.

Present Attack.—He was treated locally for 4 days with penicillin cream, after which time intramuscular injections of penicillin were given. When he had received 8 three-hourly injections to a total of 320,000 units he developed a generalized urticaria and had a temperature of 101° F. (38.3° C.). Three capsules of "benadryl" (150 mg.) were given over 24 hours with entirely satisfactory results, the urticaria disappearing.

Case V

A 19-year-old youth, with impetigo (beard area), giving a history of penicillin sensitivity. He was admitted to hospital on July 22, 1946, having been treated elsewhere with penicillin cream for impetigo of the face. He thought this had made the condition worse. He was then treated with intramuscular penicillin for 26 three-hourly injections of 40,000 units up to a total dose of 1,040,000 units, and at the same time a gentian-violet lotion was applied to the face. The local condition showed considerable improvement, but on July 30 penicillin cream was again applied and the skin relapsed.

Present Attack.—On Aug. 11 it was decided to give him a further course of penicillin, but by the next day he had severe generalized urticaria with oedema of the eyelids, swelling of both wrists, and an effusion in both knee-joints. Three capsules of

"benadryl" (150 mg.) were given on that day, and on the 13th the urticaria had gone, though the oedema around the eyes and wrists persisted. This too had subsided by the next day, and the "benadryl" was continued until a total dose of 450 mg. had been given over 3 days with entirely satisfactory results. On the following day, however, there was a relapse, both of the oedema around the eyes and wrists and also of the urticaria. This time it was treated by ephedrine, and the condition subsided gradually over 5 days. The temperature was normal throughout.

Case VI

A youth aged 18. The diagnosis in this case was giant urticaria and drug sensitivity. There was no history of previous allergy or sulphonamide administration. The patient was a seborrhoeic subject and had some lesions of seborrhoeic dermatitis on the chest of some two months' duration.

He was admitted on July 19, 1946, with an acute oedema of his penis giving it a corkscrew appearance. He had always had phimosis. There was no evidence of suppurative or urethral discharge, and his Wassermann and Kahn reactions later proved negative. He was given two divided doses of adrenaline *q.viii* (0.5 ml.) and ephedrine gr. 1/2 (32 mg.) t.i.d., and a course of sulphathiazole, 1 g. 4-hourly, was begun. Next day, there being little change, the treatment was repeated. By the 22nd, however, after receiving 15 g. of sulphathiazole, there appeared a generalized toxic erythema and the scrotum also became oedematous. This was ascribed to the sulphonamide, and the drug was discontinued. A blood count showed: W.B.C., 17,500 (polymorphs, 72%; lymphocytes, 25%; mononuclears, 2.5%; eosinophils, 0.5%). On the 23rd the skin in both groins was weeping. He was treated with calamine lotion and luminal gr. 1/2 thrice daily, and showed steady improvement, as the generalized erythema faded and the weeping areas dried and became inactive.

Present Attack.—On July 27, after receiving a total of 6 gr. (0.4 g.) of luminal, there was slight swelling of the dorsum of the left hand. On the 28th the dorsa of both hands had swelled and two bullae had appeared in the third and fourth finger clefts on the right side, and both thighs, moreover, showed large erythematous and urticarial patches. Treatment was started with "benadryl," a capsule (50 mg.) t.i.d., with very satisfactory results in so far as the urticaria and the oedema subsided within 24 hours. The bullae, however, noticeably increased in size, and four developed on the dorsum of the right hand and one at a similar site on the left. It was then decided to aspirate these as they interfered with flexion of the fingers; some 5 ml. of clear fluid was withdrawn from each. By the 30th no more urticaria had appeared, and the "benadryl" was discontinued after 450 mg. had been given; though the bullae had to be aspirated again on this date.

Improvement was then rapid, and, apart from peeling of some skin that had been affected by the bullae, by Aug. 2 there was no lesion requiring treatment. On the 5th another attack of swelling of the penis and an exacerbation of the seborrhoeic lesions in the groin occurred. As with the previous attacks there was no elevation of temperature, and a blood count showed the W.B.C. to number 10,500 (polymorphs, 63%; lymphocytes, 32%; mononuclears, 3.5%; eosinophils, 1%; basophils, 0.5%). This relapse was treated with "benadryl," one capsule (50 mg.) three times a day. There was great improvement within 24 hours, and by 48 hours the oedema had completely subsided. A total dose of 450 mg. was given for the relapse.

Summary

An account is given of 6 cases of urticaria treated with "benadryl," of which 5 were associated with intramuscular penicillin therapy.

The doses ranged from 150 to 450 mg. in each case.

A reaction was noted in one patient who received concurrent adrenaline.

The results obtained showed success in five cases and failure in one (Case III). Two of the successes relapsed (Cases V and VI), one of which was again treated with the drug with a satisfactory result.

I am grateful to Major B. Schwartz, R.A.M.C., and Major L. Sefton, R.A.M.C., for their help, and to Messrs. Parke, Davis and Co. for kindly supplying me with the "benadryl."

In a White Paper entitled *Organization of the Colonial Service*, recently issued by the Colonial Office, the need for large reinforcements is stressed. Government policy aims at progressive self-government by the peoples in the Colonies, and it is from them that many of the recruits must be drawn. The potentialities and abilities of these peoples have been neglected in the past; they lack the opportunities for education available to candidates in the United Kingdom and Dominions; so the creation of educational facilities will be immediately undertaken by the Government, and the sum of £1,000,000 has already been allocated over the next ten years to enable selected Colonial candidates to receive higher education.

CONGENITAL PATENCY OF THE FORAMEN OVALE CORDIS, WITH SUDDEN DEATH DURING EXERCISE TOLERANCE TEST

BY

C. E. LUMSDEN, M.B., Ch.B.

Late Major, R.A.M.C.

(From the Department of Pathology, Aberdeen University)

The following case of congenitally patent foramen ovale of the heart in an adult is reported, as it presents a most unusual clinical termination: sudden death from acute cardiac failure.

Clinical Features

The patient, an able-bodied Indian seaman aged 25, with six years' service, was at the time in question serving aboard a light destroyer of the Royal Indian Navy. He was of good-class Muslim family from the Upper Punjab. There was no past history of illness or disability. He had passed his several medical examinations before and after his enrolment in the R.I.N., and his medical records were clear. He had been a notably enthusiastic recruit, with a good record of service, free of any default.

Towards the end of November, 1942, his ship had had a sharp engagement at sea against superior enemy surface forces, and after a running battle of several days, from which H.M.I. ship emerged victorious, it returned, crippled, to port for refitting. The patient reported sick on the day after the arrival in port, being unable to attend the victory parade given in honour of the ship's gallant action. He stated that since the recent naval action, about five days before, he had felt "peculiar," and that if, during the course of his duties, he ran, he felt dizzy, became out of breath, and could feel his heart beating in a peculiar way. These symptoms alarmed him because he had never noticed them before.

On examination by the medical specialist he appeared of good physique and in good health, and had no dyspnoea at rest. His pulse was regular at 68 per minute. He did not exhibit appreciable cyanosis on examination; there was no oedema of the ankles. On auscultation of the heart no murmurs were detected. The patient, a cheery and co-operative lad, then said he "could best demonstrate his complaint after a run" (medical specialist's report), an exercise tolerance test to which his examiner saw no objection. Accordingly the patient was instructed to run to the end of a corridor, a distance of some 20 yards (18 m.). At the end of the corridor, just as he turned to run back, he fell in a faint, from which he did not recover, despite the medical attention at hand. He died in three to four minutes.

Findings at Necropsy

A post-mortem examination was made two hours after death; it was primarily required for purposes of a medico-legal report.

External Examination.—The body was well nourished, of average stature, and of normal skeletal development. There was no clubbing of the fingers or toes, no oedema of the ankles or of subcutaneous tissues anywhere, no cutaneous haemorrhages or other congestive features of the head or neck, and no jaundice.

General Internal Examination.—The muscles and tissues of the body generally were well coloured, there being no evidence of any anaemia. There was no excess of free fluid, nor were there any abnormal contents in any of the body cavities. The organs, apart from the heart and aorta (q.v.), were healthy and did not show any evidence of chronic venous congestion. The blood was still fluid in the heart and vessels, and there was no cardiac, pulmonary, or cerebral embolism.

Cardiovascular System.—The pericardial sac contained only some 3 to 4 ml. of clear straw-coloured fluid. There was no pericarditis. On inspection and palpation the heart was distinctly enlarged, mainly due to a relatively enormous distension of the right atrium, which contained some 9 to 10 oz. (250 to 280 ml.) of dark fluid blood. The great afferent veins, superior and inferior, were unduly swollen with blood. The left side of the heart was not appreciably enlarged, but the left ventricular wall felt unduly hard and thick. The ascending aorta was prominent, and its wall was palpably thickened and rigid. On dissection of the heart the abnormal findings were: (1) a patent foramen ovale between the atria, fairly high up; (2) an advanced and confluent atheroma of the wall of the ascending aorta, with a diminishing degree of atheroma in the descending aorta, thoracic and abdominal; and (3) a distinct myo-hypertrophy of the wall of the left ventricle. The margins of the "foramen" ovale were unduly separated, and the superior curtain of the endocardial reflexion formed a large semilunar flap, manifestly capable of occluding the opening when the atria were not abnormally distended—that is to say, in the collapsed state of the heart after

draining most of the blood from it—but when the atria were distended with fluid, or on stretching the septum widely with the fingers, a semicircular fenestra or opening some 8 to 10 mm. in diameter was exposed, permitting of ready communication between the atria. The atheroma of the aorta started beyond the aortic valve and surrounded the orifices of both coronary arteries, so that the inlets to each of these appeared distinctly narrowed though readily distensible. The atheromatous plaques as far as the arch were confluent, so that the whole aortic wall to the level of the arch was thickened, hard, inelastic, and appreciably, though not grossly, dilated. The change appeared to be strictly intimal, resembling the ordinary atheroma commonly seen in much older subjects. There was no medial change, and the appearances were not at all suggestive of syphilis. There was no sign of any coarctation of the aorta. Both coronary arteries were exposed carefully throughout, but these were innocent of any atheromatous change. The myocardium was of good colour and showed no evidence of ischaemic pathology. The pulmonary valve was not at all stenosed, and the wall of the pulmonary artery was healthy throughout. There was no patency or persistence of the ductus arteriosus. There was no perforation in the interventricular septum. All the heart valves were normally constructed and were devoid of any apparent pathological change. The valve curtains of the mitral valve exhibited no thickening or any undue rigidity; the chordae tendineae and papillary muscles revealed no malformation. The valve just admitted three fingers, and no more; we find at necropsy that many apparently "normal" hearts do. Only the wall of the left ventricle showed any degree of hypertrophy, and this was of moderate degree. The whole heart, emptied of blood, weighed 310 g. Blood collected from the heart, post mortem, gave a negative Kahn test result.

Respiratory System.—The lungs were comparatively dry and were air-filled throughout. There was no consolidation or oedema. The upper air-passages were clean, dry, and healthy looking.

Liver and Spleen.—These organs were not enlarged and showed no visible evidence of any chronic venous congestion. A frozen section of the liver revealed no fatty change.

Urinary System.—The kidneys were of average size. The parenchyma showed no appreciable pathological changes. The urinary bladder was healthy and contained a few ounces of clear straw-coloured urine.

Nothing abnormal was found in the examination of the brain. The pituitary, thyroid, and parathyroid glands, the adrenal bodies, prostate, and testes exhibited no pathological features. There was no enlargement of any of the regional lymphatic nodes. The osseous and muscular systems showed no obvious morbid change.

Histological Examinations.—These were restricted to the wall of the aorta, the liver, and one kidney. The aorta showed only intimal change, and there was no perivascular infiltration of the vasa vasorum such as to suggest any syphilitic aetiology. There was no microscopical evidence of chronic venous congestion of the liver. The renal parenchyma showed no degenerative changes, and there was no interstitial cellular infiltration.

Commentary

Clinically, the cause of death was manifestly syncopal, and at necropsy this appeared to be referable to the acute dilatation and engorgement of the right atrium. This atrial distension was strikingly greater than anything I have seen in cases of fatal syncope from other causes—in fact, in any other necropsy. It was considered highly probable that the distension was directly due in some way to the congenital persistence and patency (the latter, terminally) of the foramen ovale. The appearance of the specimen at necropsy suggested that physiological occlusion had been possible. There had been no prolonged decompensation or significant leakage through the defect, since there was no evidence of congestive sequelae of any chronic nature in the tissues or organs of the body generally.

The emphatic assurance given by the patient that his symptoms had developed suddenly, coupled with his demeanour, which was one of surprise and pique that such an absurd misfortune should have befallen him in the hour of his triumph, forced me to the conclusion that there was an immediate cause-and-effect relationship between the recent strain on the heart and its sudden failure. It may be that during the prolonged nervous excitement and physical activity of the naval action (at one phase the men had been at action stations continuously for sixty hours) there had been dilatation of the atrial defect and an unaccustomed or excessive leakage through that defect from left to right. In this case the atheromatous condition of the aorta may have contributed by increasing the load on the heart; possibly a terminal acute incompetence of the mitral valve may be the missing link in the chain of events. In this

spect the definite absence of any appreciable degree of limonary oedema is recalled.

Alternatively, it may be argued that the acute cardiac failure as due to coronary ischaemia, purely and simply. Certainly here was aortic atheroma here, and this involved the wall in the immediate vicinity of the orifices of the coronary artery. Similar cases of sudden death among soldiers in training during the recent war were usually ascribed to coronary chaemia. If the present case was due to that cause then the extreme dilatation of the right atrium requires explanation. It is certainly an interesting and apparently insoluble pathological problem.

THE COUGH SYRUP

BY

ELDON M. BOYD, M.D.

(From the Department of Pharmacology, Queen's University, Kingston, Canada)

While syrups are commonly used as correctives for the disagreeable taste of medicines, there is probably no one group of drugs so consistently prescribed and dispensed in a syrupy vehicle as are expectorants and antitussives. Many drugs in this category could be prescribed as tablets, pills, capsules, etc., and any undesirable taste thus effectively dealt with; but they continue, for the most part, to be given in the form of a syrup. A good proportion of the syrups listed in the British and United States *Pharmacopoeias* contain drugs commonly held to be expectorant, while the number of non-official and patent cough syrups is legion. These considerations lead to the question of what, if any, are the pharmacological and therapeutic effects of syrups *per se* in the treatment of cough, and whether there is any justification for their continued use in cough medicines.

Historical

Why and when cough syrups were first used is a moot question in the investigation of which many interesting facts may be brought to light. Sugar, the basis of syrups, was first manufactured from the sugar-cane in Bengal, where it was called *sharkarā*, an old Sanskrit word which meant a substance made up of small grains (Flückiger and Hanbury, 1879). Etymologically the word *sharkarā* or *śarkarā* is the root of many modern words, such as sugar, sucrose, saccharin, syrup, sherbet, etc. From the Sanskrit the Persians changed the word to *shakar* and the Arabians to *sukkar*; in early Latin it became *saccharum*, and by mediaeval times had altered to *succarum*: from these words there was a gradual transition to the early French word *sukere*, then *sucre*, to the early English *sugre*, then *suger*, and finally to *sugar*. About the 8th century the cultivation and manufacture of sugar spread eastward from India to China, the Malay and the Pacific Islands, and westward through Persia to the Arabian Empire. Arabian physicians, especially Rhazes and Avicenna, are usually credited with introducing syrups into the therapeutic armamentarium. The word "syrup" is generally said to originate from an Arabic word, *sharab*, which meant a drink, but it is obvious that this Arabic word was derived from the more ancient Sanskrit source. It is interesting to note also that our word "candy" may be traced back to the Arabic word *kandān*, which meant a lump of sugar.

No evidence has been found that any one physician was responsible for the introduction of the cough syrup, and it seems most likely that the common people found, by trial and error, that sugar or syrups or candy held in the mouth would relieve a cough. In recent years Gordonoff (1935) has shown, using modern techniques, that the sucking of candy has a pharmacological effect upon the respiratory tract, which he interpreted as meaning an increased output of bronchial or respiratory-tract fluid: In a later extensive review of the physiology and pharmacology of expectorants Gordonoff (1938) has made the statement, without references, that sugars were ancient folk-remedies for colds. Should this be true—and it would appear to be correct from what evidence is available, or rather lack of evidence to the contrary—it is readily apparent how cough syrups were introduced into medical practice, because

the early pharmacopoeias were, to a large extent, compilations of folk-remedies of earlier days. The retention of the cough syrup in subsequent editions of the pharmacopoeias and in the practice of medicine is readily understood when one looks over the list of drugs of disagreeable taste described in textbooks of materia medica and therapeutics of the last 200 years and even to-day—e.g., Beckman (1945).

Gordonoff (1935, 1938) claims to have proved that syrups do act as expectorants by augmenting the output of bronchial or respiratory-tract fluid. He noted that the duration of action is short, and hence advised giving syrups at intervals of about two hours. He also reported that maltose and sucrose, but not lactose, had expectorant properties.

Antitussive Action of Syrup in Man

Syrupus, B.P., was given in doses of two teaspoonfuls t.i.d. or q.i.d. to 28 patients complaining of cough due, for the most part, to an attack of the common cold. I interviewed these people at short intervals, and recorded the results of "therapy" as effective or ineffective in relieving the cough. Where there was any doubt as to the syrup's having had an antitussive action the case was listed as ineffective. It should be mentioned that the patients did not know what medicine they were getting. Those who obtained relief from cough with syrup reported, on the average, that the antitussive effect lasted about two hours. In this small series of cases 68% got complete relief from cough, and in the remaining 32% there was little or no antitussive effect. Allowing for the subjective factor, which could not be controlled because a true control group was not possible, it seems reasonable to conclude that syrup alone actually did have some antitussive properties. In view of the fact, as will be described below, that syrup given by stomach tube to animals did not augment the output of respiratory-tract fluid, and in view of the short antitussive action of the syrup in man, it seems most reasonable to conclude that syrup taken by mouth exerted a linctus-like action by soothing the irritated pharynx and upper respiratory tract—irritation which presumably was responsible for cough in approximately two-thirds of the patients studied. The evidence from these experiments would favour the retention of syrup as a vehicle for expectorant and antitussive medicines. The results suggest that when an expectorant mixture is given in a syrupy vehicle the syrup exerts an immediate direct demulcent action, while in an hour or two the effective expectorant drugs in the mixture take over the same function but in a different way—namely, by augmenting the output of respiratory-tract fluid.

Syrups and the Output of Respiratory-tract Fluid

It was next investigated whether syrups alone have a true expectorant action, as claimed by Gordonoff. There is no unanimous agreement on the definition of an expectorant. Faced with this problem, when research on expectorants was begun a number of years ago in this department of the university, the decision was made to leave in abeyance the question of a definition and to investigate those pharmacological and therapeutic properties of reputed expectorants which might offer an explanation of their mode of action. Older methods for studying the nature of expectorant action were tried and discarded for one reason or another. The first new method used was to measure the water content of the tracheal, bronchial, and alveolar portions of the respiratory tract before, and at intervals after, administration of an expectorant drug. The technique was applied to a study of the creosotes and guaiacols (Boyd and Johnston, 1940; Connell, Johnston, and Boyd, 1940) and, while reasonably satisfactory, the procedure was cumbersome, time-consuming, and, more seriously, it did not provide the information most desired, so that it too was abandoned.

Gunn (1927) has stated: "If it were as easy to determine the quantity of bronchial secretions as it is to measure the amount of urine, there would be by this time no such vagueness in regard to the effect of expectorants as still exists." The problem, therefore, was to find a satisfactory method for quantitatively measuring the output of bronchial secretion or, as is used in this laboratory, respiratory-tract fluid (R.T.F.)—a term which does not designate the site of origin, at present imperfectly understood, of this fluid in the respiratory tract. Perry and Boyd (1941) eventually worked out a technique for determining the exact output of this fluid and of providing a means whereby

it could be collected and analysed. This method, with subsequent modifications, improvements, and variations (Boyd, Jackson, and Ronan, 1943; Boyd and Ronan, 1942; Boyd and MacLachlan, 1944; Boyd, Perry, and Stevens, 1944), consists essentially in collecting R.T.F. through a T-cannula ligated into the trachea of lightly anaesthetized or decerebrate animals, with the inhaled air warmed to body temperature and saturated with water vapour. By means of this technique it has to date been possible to measure the effect upon the output and composition of R.T.F. of the following drugs: ammonium chloride, ammonium carbonate, and thymol (Perry and Boyd, 1941); various guaiacols and creosotes (Stevens, Ronan, Sourkes, and Boyd, 1943); sympathicomimetic amines (Boyd, Jackson, and Ronan, 1943); ether (Boyd and Munro, 1943); inhalation of ammonia (Boyd, MacLachlan, and Perry, 1944) and steam (Boyd, Perry, and Stevens, 1944); paregoric, camphor, benzoic acid, and alcohol (Boyd and MacLachlan, 1944); theophylline ethylenediamine, potassium citrate, and chloroform (Boyd, Palmer, and Pearson, 1946); ipecacuanha (Perry and Boyd, 1941; Boyd, Palmer, and Pearson, 1946); organic and inorganic iodides (Boyd, Blanchaer, *et al.*, 1945), volatile oils, balsams, terpene hydrate, and terebene (Boyd and Pearson, 1946); parasympathicomimetic drugs and atropine sulphate (Boyd and Lapp, 1946; Lapp and Boyd, 1946; Boyd and Munro, 1943); sulphonamides (Boyd and Dorrance, 1946) and expectorant saponins and related drugs (Boyd and Palmer, 1946). Further studies are in progress.

In the investigation described here, the same technique was applied to a study of the effect of several pharmacopoeial syrups on the rate of output of R.T.F. in approximately 200 animals, including guinea-pigs, rabbits, and cats. The general procedure was to arrange the animals for collection of R.T.F., and at the end of three hours, when the rate of output had been at a plateau level for two hours, administer the respective syrup by stomach tube. The dosage ranged from 0.1 to 10 ml. per kilogramme body weight, and when the volume was below 10 ml. per kg. it was made up to that volume with water. In previous studies from this laboratory it has been repeatedly shown that water given by stomach tube in doses up to 10 ml. per kg. body weight has no effect upon the output of R.T.F. On the average, somewhat over twenty animals were used for each syrup given to each species. To standardize the presentation of results the mean output of R.T.F. per kg. body weight per hour was first determined for the two control hours immediately preceding the administration of the syrups. The mean output each hour afterwards was then found, and any increase in the rate of excretion expressed as a percentage of the initial control two-hour output. In calculating these means all values from all doses of syrups were included, since no syrup, with the possible exception of syrup of tolu, had any significant effect on the output of R.T.F. in any of the doses studied. The results thus determined are presented in the accompanying Table.

Table Showing Effect of Several Pharmacopoeial Syrups on Rate of Output of Respiratory-tract Fluid in Animals

Syrup	Species	Change in Output of R.T.F.*			
		1st Hour	2nd Hour	3rd Hour	4th Hour
Simple syrup	Rabbit	% +6	% 0	% -10	% -15
	Cat	-13	-11	-16	+7
Wild cherry	Rabbit	-22	+16	+8	-22
	Guinea-pig	-24	-26	-20	-21
Squill	Cat	-18	-16	-14	-9
Liquorice	Rabbit	-2	+21	+18	+8
	Cat	+32	+33	+47	+37
Tolu	Rabbit	+93	+43	+28	+4
	..	+10	+6	+28	+21

Syrupus, B.P., syrupus pruni serotinae, B.P., syrupus scillae, B.P., syrupus zingiberis, B.P., and syrupus glycyrrhizae, U.S.P., had no significant effect on the rate of output of R.T.F., even in doses which would correspond to a pint (568 ml.) or quart (1.14 l.) taken by mouth by an average man, on a body-weight basis. Syrupus toluanus, B.P., slightly augmented the output of R.T.F. in cats and rabbits. From the results with this group of syrups it is apparent that the syrup in a cough syrup has little or no effect on the rate of output of R.T.F. when it is given by stomach tube.

Conclusions

From the results of these experiments on animals and man the following conclusions are indicated. First, the syrupy vehicle of a-cough syrup exerts a short demulcent effect on the mucosa of the pharynx and upper respiratory tract, and if cough is due to irritation of this mucosa the syrup has an antitussive effect *per se*. Secondly, when the bulk of the volume of syrup enters the stomach it has little or no expectorant property in itself, in the sense that it does not increase the rate of output of soothing respiratory-tract fluid. Thirdly, effective expectorant drugs added to the syrup begin to exert an antitussive action, again in the sense that they increase the output of respiratory-tract fluid, at about the time that the local antitussive action of the syrup alone has begun to wear off. These experiments offer a logical explanation of the time-honoured use of expectorants in a vehicle of syrup, producing a cough syrup, and at the same time justify the continued use of this form of prescribing and medication.

I wish to acknowledge the technical assistance of Mrs. J. P. Grant, and also the receipt, on behalf of Queen's University, of a financial research award in aid of this work from the Ciba Company, Ltd., of Montreal.

Medical Memoranda

An Accessory Liver in an African

While accessory spleens are commonly found at necropsy both in Europeans and in Africans, accessory livers are extremely rare. Rolleston and McNeen (1929) were able to record only a very few cases, and in the literature available to me since their publication I have not been able to find reports of other cases. Thus this record of the occurrence of an accessory liver in an African may be of interest.

In the body of an adult male African of unknown tribe, dying of bronchopneumonia, a dark tumour, shaped like a fat cigar, about 3.5 by 1 cm. in its greatest dimensions, was found adherent to and partly embedded in the anterior surface of the pancreas at about the junction of the head and body, the longest axis being transverse. It was attached by a delicate pedicle which disappeared into the substance of the pancreas and, under the circumstances of the necropsy, was not traced further. The tumour was not attached to the liver. It was of darker colour than the true liver, which had no anatomical abnormalities.

Microscopically it proved to be hepatic tissue showing the normal liver architecture, enclosed in a delicate fibrous-tissue capsule with arteries, veins, and bile ducts running beneath the capsule, and these left the accessory liver at a small hilum and ran into the pancreas. Both the true liver and the accessory liver showed pathological changes, but these were much more pronounced in the accessory organ. They consisted of collections of fibroblasts and chronic inflammatory cells in the portal areas, with an increased amount of fibrous tissue surrounding and partially delimiting the periphery of some of the lobules. The rather dilated central veins were surrounded by liver cells containing considerable amounts of fat in large and small droplets, but the peripheral cells were free of fat. Considerably increased amounts of pigment were present—as granules in the Kupffer cells, in the sinusoids near the periphery as amorphous masses, and in the portal cell collections. All these changes were much more noticeable in the accessory liver.

DISCUSSION

Most of the accessory livers recorded by Rolleston and McNee (1929) were attached to, or in close proximity to, the liver; mostly in the hepatic ligaments or directly attached to the liver or gall-bladder. One case is recorded by them of hepatic tissue in the omentum and scattered over the peritoneum; and one with a nodule of liver tissue in a suprarenal gland. None had such an attachment to the pancreas as was found in this case. They do, however, record the occurrence, reported by Mohamet, of an accessory liver attached to the tip of the gall-bladder in a case of cirrhosis; the accessory liver was also cirrhotic.

Permission to publish has been granted by the D.M.S., Uganda.

Persistent Vomiting in Infants treated by Continuous Nasal Drip-feeds

The difficulty of getting an infant suffering from severe and persistent vomiting to take enough food by ordinary means is well known. With a view to overcoming this difficulty I have in many cases during the past three years adopted the method of drip-feeding described below.

TECHNIQUE

A small soft rubber catheter (size 4-6, according to the size of the infant) is lubricated and passed through one of the nostrils into the stomach. This is easily accomplished, with little discomfort to the infant. The free end of the catheter is attached to an ordinary blood transfusion set, the bottle of which contains the prescribed feed. The amount of milk mixture required by the infant is calculated for 24 hours, and this is run into the stomach by means of a slow drip. A rate of eight drops a minute will deliver 20 fl. oz. (568 ml.) in 24 hours. If a larger feed is required, the rate can be increased accordingly. The method is simple and can be easily mastered by trained nurses.

Before starting this regime of feeding the stomach is washed out and sufficient glucose saline (5%), or Hartmann's solution, is given by this method to combat dehydration. The actual feeding mixture will depend, naturally, on the requirements of the case concerned, and may consist of a milk mixture or a pure protein preparation, such as casein hydrolysate. Feeding in this way can be continued over a period of days until improvement occurs, when it is discontinued and normal feeding resumed.

DISCUSSION

During the last three years I have used the above method of feeding for infants suffering from incessant intractable vomiting, for which no organic cause can be found, and for very weak wasted babies. In the first type of case the vomiting seemed to occur as a sequela to an attack of gastro-enteritis which had subsided, and may possibly have been due to a form of habit vomiting (Holt and MacIntosh, 1940). In weak malnourished infants the strain of having to be fed with small feeds at frequent intervals is exhausting, and it was regarded as far less tiring for the infant if it could be fed in a way unlikely to cause any such exhaustion. With this in mind the continuous-drip method was adopted. I have also used this method in other selected cases; notably, in infants suffering from rumination and in young children suffering from cyclical vomiting, during severe attacks. The chief advantage of this method is that the food requirement of the infant is maintained over a long period, without at any time overloading the stomach and so producing a recurrence of vomiting; and the patient is assured of adequate rest by not having to be disturbed at frequent intervals, as would occur if feeding by normal means were carried out. Where sedation by means of drugs is an essential part of the treatment, as in cases of rumination and habit vomiting, this is a very important consideration. I prefer this method to the usual form of oesophageal feeding of weak marasmic infants because it obviates the passing of a tube into the oesophagus several times a day.

I am very grateful to Dr. K. H. Tallerman, consulting paediatrician to the Essex County Council, for his help and encouragement in preparing this note, and to Dr. E. Miles, medical superintendent, for permission to publish it.

Reviews

THE DOCTOR-PATIENT RELATIONSHIP

The Human Approach. A Book for Medical Students. By Henry Yellowlees, M.D., F.R.F.P.S., F.R.C.P., D.P.M. (Pp. 189. 10s. 6d.) London: J. and A. Churchill. 1946.

This is a book for which we have long been waiting. It may be described as a textbook of the doctor-patient relationship. Primarily intended for medical students, it would be read with great profit by all qualified doctors and not least by hospital physicians and surgeons and even psychiatrists themselves. It is possible that this volume will not help the student much in passing his examinations, but if he will learn, mark, and inwardly digest all the admirable common sense and enlightened appreciation of the other fellow's point of view which it contains, he will certainly be a much better doctor. He can do this not only with profit but with enjoyment too, for the style is delightfully humorous and the homely examples can be appreciated by those who are in no way versed in academic psychiatry. The book does not deal either with elementary psychology or psychiatry, but gives some simple explanations of psychopathology, a pathology from which none of us can escape since no one can be perfectly adjusted to life and everyone uses various devices to get round these maladjustments. It is with these devices that most of the book is concerned, but there are excellent chapters on the much discussed problem of rehabilitation, which must after all be primarily psychological, on the doctor's relation with the legal profession and his behaviour in court, on medical etiquette and ethics, and on the medical curriculum. A book to be thoroughly recommended.

MANAGEMENT OF VENEREAL DISEASES

Aids to the Diagnosis and Treatment of Venereal Diseases. By T. E. Osmond, M.B., M.R.C.S. (5s.) London: Baillière, Tindall and Cox. 1946.

Students and general practitioners and perhaps many specialists will welcome this work as giving in a very handy form (138 octavo pages) an account of the management of venereal diseases and of some others commonly dealt with by specialists in this branch of medicine. The author has had many years' experience in venereal diseases on both their clinical and laboratory sides, and during the late war was adviser on them to the Army.

Approximately 44 pages are devoted to gonorrhoea and 52 to syphilis, the remainder of the book containing accounts of soft chancre, granuloma venereum, lymphogranuloma inguinale, trichomonas infestation, non-specific urethritis, balanitis, and condylomata acuminata; serum tests; technical methods such as irrigation, staining by Gram's method, dark-ground microscopy, collection of specimens, and injections; prophylaxis; and the social aspects of venereal disease. The size of the work does not permit of an elaborate account of any of the above subjects, but sufficient has been given in most of those commonly met to enable the reader to deal with them. Indeed, the author is to be congratulated on having packed into such a small space and in such readable language so much useful information.

It is pleasant to find in this work so little that seems to call for criticism, but one of the few points which might be revised concerns the arrangement of some of the sections. One would think that diagnosis should follow symptoms; here it often precedes the latter. On page 58 the gonococcal fixation test is sandwiched between an account of the Kahn test and interpretation of the Kahn and Wassermann tests, and this is followed by a schematic presentation of these tests, the principles of which were described before the paragraph on the gonococcal test. On page 100 there is a little on serum diagnosis of congenital syphilis, yet on pages 101 and 102, under the principal heading of "Late Congenital Syphilis," subhead "Central Nervous System," there is more on serum diagnosis in the early weeks of life. Again, the treatment of congenital syphilis, into which the general treatment of syphilis is interpolated, would be more conveniently described in a single section.

THE INTIMATE STUDY OF BACTERIA

The Bacterial Cell in its Relation to Problems of Virulence, Immunity and Chemotherapy. By René J. Dubos. With an addendum by C. F. Robinow. Harvard University Monograph in Medicine and Public Health, No. 6. (Pp. 460; illustrated. \$5.00 or 28s. 0d.) Massachusetts: Harvard University Press; London: Oxford University Press. 1945.

It has long been a reproach to the science of bacteriology that its study has been pursued only with limited ends in view—usually restricted to the apparent needs of one of its several branches. A more fundamental comprehension of bacterial behaviour, which in the end would serve the science in all its forms, has been neglected. But in recent years the depths reached even by *ad hoc* inquiry have vastly increased: progress in the study of immunity and chemotherapy have in particular demanded that we should know far more about the structure, chemical constitution, and metabolic behaviour of bacteria. It is mainly with these matters that Dr. René J. Dubos deals in *The Bacterial Cell*, a Harvard University monograph of the proportions of a full-sized book, and having a bibliography occupying 70 pages. Its main subjects are the structure of bacteria as revealed by direct observation, their physico-chemical properties, and in particular the mechanism of their staining, the analysis of their structure by means of enzymes and antigen-antibody reactions, variation, the nature of virulence, methods of immunization, and the mechanism of bacteriostatic and bactericidal action. These subjects are deeply involved in every advance for years past in the study of bacteria generally, and particularly in the therapy of microbic infections. The therapeutic success of the sulphonamides, and later of gramicidin and penicillin, has been largely responsible for the immense effort now directed at unravelling the secrets of bacterial metabolism, and now we have a fair understanding of how most antibacterial agents work, penicillin being the notable exception. An addendum to the text is a description by C. F. Robinow of the nuclear apparatus of rod-shaped bacteria as revealed by Feulgen staining; this is profusely illustrated, as indeed are other parts of the book which deal with morphology.

As a source of well-edited information on vital subjects, many aspects of which are not by any means generally familiar, and as a stimulus to thought and inquiry, this book will be valued by all progressive bacteriologists. The quotations which head each chapter are a delightful and sometimes humorous feature; their sources include not only the works of Pasteur and Ehrlich but the Bible and *Alice in Wonderland*.

AMPUTATION PROSTHESES

Amputation Prosthesis. Anatomic and Physiologic Considerations, with Principles of Alignment and Fitting Designed for the Surgeon and Limb Manufacturer. By Atha Thomas, M.D., F.A.C.S., and Chester C. Haddan. (Pp. 305; 207 illustrations. 50s.) Philadelphia and London: J. B. Lippincott Company.

A basic knowledge of the surgery of amputations, the specification and supply of suitable prostheses, the tuition of the disabled after limb-fitting, and complete rehabilitation of the patient are more necessary to-day than ever before. This applies not only to the surgeon deciding upon the exact operative procedure but to all who have any responsibility whatever, both for the supply and maintenance of the prostheses and the well-being of the patient. The preface of the book attempts to make this manifest. Many well-known books in various countries are mentioned as worthy of reference, among them being Muirhead Little's book written nearly twenty-five years ago. This is still a standard reference book and even now gives excellent guidance in surgery and the fitting of artificial limbs.

Mention is made of a tendency throughout history to exaggerate the values of prostheses, more especially artificial arms and hands. The success of any artificial limb, after it is correctly fitted, depends mainly upon the patient and the tuition given. The authors suggest that a limb-maker might be consulted before an amputation site is decided upon. This is surely a surgeon's sphere of work and it would be more satisfactory for the surgeon to have a knowledge of the types of limbs available or to consult another surgeon with this knowledge. Skin traction is treated at some length, especially in connexion with the guillotine operation. Surgeons in the British Army preferred to make flaps loosely sutured in the first place to allow for drainage. Only a very short summary is given

of the important treatment of the stump by bandaging, and it is doubtful if it can be clearly understood. The illustrations show a thigh stump being bandaged by the patient standing erect; it is not possible for the patient to secure firm pressure in this way. The below-knee stump is shown being bandaged by another person; the patient can and should do this himself. Pylons are stated to cause "faulty habits of walking which may be difficult to overcome," but provided the patient has not used the pylon too long he can be taught to walk satisfactorily on an articulated limb and avoid the long use of crutches, which may induce "faulty habits."

The survey of the materials used in making prostheses is not sufficient to appeal to a limb-fitter, nor is it of great value to surgeons. The limbs illustrated are not typical of those used in this country. Better information would be obtained from a catalogue, such as those published by limb-making firms. One cannot agree that the mechanism of walking "is a perpetual falling and self recovery" as illustrated. The text and diagrams in this section need very cautious study. Many of the statements dealing with arm amputations and prostheses are debatable. A particular type of mechanical hand, copiously illustrated, shows tools held in the hand. It has been found here that better control of a tool or implement is obtained by the use of an appliance fitted to the artificial arm and interchangeable with the artificial hand. The tool is used for heavy work, and the hand for light work or cosmetic purposes. The cineplastic operation, with the special prosthesis, was tried on many patients some years ago in this country, and results were not satisfactory. It is pleasing to note the recommendation that children should be fitted in early childhood, as is the practice here. There is a good section on rehabilitation, though it is only a summary.

The book is very well produced, fully illustrated, and easy to read. One could not recommend it as a standard reference book for surgeons or advanced students in this country. The design of limbs varies so much in each country that a very comprehensive book would be required to cover the methods used in all countries.

Notes on Books

On Feb. 28 of this year Prof. J. Z. YOUNG, F.R.S., gave his inaugural lecture after appointment to the chair of anatomy at University College, London. The title of this thought-provoking address was *Patterns of Substance and Activity in the Nervous System*, and those who heard it as well as those not fortunate enough to be present will be glad to know that well-printed copies are now obtainable in pamphlet form from H. K. Lewis and Co., 136, Gower Street, W.C., price 1s. 6d. net. Prof. Young holds that for the progress of teaching and research in medicine what is needed is not a mere collaboration of anatomists and physiologists but to a considerable extent a fusion of the two. "To be able to understand and control living material, and in particular our own, we must regard it in various ways. We shall not make useful studies of the structure of the substance unless we bear in mind that it is continually changing, taking part in activities. Nor conversely can we profitably study the activities unless we remember that they are directed towards the conservation of the pattern. . . . This is tantamount to saying that anatomy and physiology cannot exist as separate sciences, and this indeed is my belief. Further, since each particular manifestation of organization has developed and in the end returns to the dust, all biology must also be historical and include the study of embryology and evolution. There is a real danger that if each of these sciences remains separate no one will be left to study the processes of conservation of the organism."

Experiments on the Presence of Carcinogenic Substances in Human Surroundings, by THEODORE VAN SCHELVEN (Amsterdam: Kosmos Publishing Company, Keizersgracht 133: \$1.00), records an experiment in which benzene extracts of black crusts from bread and roast meat were painted on the skin of mice and induced a few tumours. The author suggests that carcinogenic hydrocarbons are produced at temperatures which cause blackening during roasting, baking or frying of food and that these substances may constitute an indispensable link in the chain of causal factors leading to "spontaneous" cancer in man. The alleged low incidence of cancer in certain populations (Eskimos and the Nubian Hadendowa) which lack fuel and therefore eat their food raw or lightly cooked is quoted in support of the hypothesis, and investigation of the tumour incidence in other populations with similar habits is urged. The argument is interesting but no more convincing than numerous other attempts to blame cancer on the habits of civilized man; ordinary civilized cookery should not produce charred food. The substance of the pamphlet is suitable for compression into an article for a medical journal but does not merit separate publication.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY NOVEMBER 16 1946

YES OR NO?

The National Health Service Bill received the Royal Assent last week and is therefore now on the Statute Book as an Act. The appointed day for the Act is April 1, 1948. Between now and that date the medical profession will have to make up its mind collectively whether or not it is to take service under the Act, whatever may be the free decision of the individual doctor. If an effective majority of practising medical men in this country, after full consideration of what the Act means for both the public and the medical profession—for both individual patient and individual doctor—decide that the Act in operation will be in the best interests of neither, then the Minister of Health will fail to secure that co-operation of the medical profession which he has acknowledged to be essential if his measure is to be successfully carried through. This week every medical man and woman on the *Register* will receive from the British Medical Association three documents. The first is the plebiscite form on which each doctor is being asked to give the answer "Yes" or "No" to the following question: "Do you desire the Negotiating Committee to enter into discussions with the Minister on the Regulations authorized by the National Health Service Act?" The second is a report on the Act by the Negotiating Committee which summarizes the contents of the Act and examines them in relation to the principles laid down by the Negotiating Committee and endorsed by the medical profession as a whole. The third document is a brief letter from the Secretary of the B.M.A. which includes the decisions of the Representative Body on some of the more important issues in the Bill—as it was when these decisions were made. The latter two documents are printed in this week's *Supplement*. Elsewhere in the *Journal* we publish an abridged version of the White Paper on the Scottish Bill and an address on the Act given at Exeter last week by Dr. H. Guy Dain, Chairman of Council of the B.M.A.

It is well to state once more that the Negotiating Committee is made up of representatives of the B.M.A., the three Royal Colleges of England, the Royal Scottish Medical Corporations, the Society of Medical Officers of Health, and the Medical Women's Federation. It is, therefore, a committee wholly representative of the medical profession. The decision whether this Committee is to enter into discussions with the Minister of Health on the Regulations of the Act lies with the individual medical man and woman. Whatever answer may be given, the Negotiating Committee will plainly be in a weak position unless a large majority fill in the Plebiscite form and return it promptly to B.M.A. House. Surely at a time like this no medical man will shirk the responsibility of coming to his own decision on a matter which will not only affect him personally but which will have an equally profound effect upon the future of

medicine. No man can afford to leave the decision in the hands of others. If everyone sends in his "Yes" or "No," then whatever the majority decision may be the Negotiating Committee will know that it can act in the full confidence that it has the solid backing of the profession in whatever course it has to pursue.

The answer "Yes" will empower the Negotiating Committee to discuss with the Minister the Regulations and Orders which will fill out what is to all intents and purposes an Enabling Act—Regulations dealing with such matters as the mode and amount of professional remuneration, terms and conditions of service, and the composition of Regional Hospital Boards. If, despite the divergences between the principles of the profession and the provisions of the Act, the profession chooses this course, then at the end of the discussions it will be able to have another look at the Act and to see how it will shape the doctor's daily work and conditions of living after April, 1948. In full possession of all the many and important details of the Regulations, and being able to assess their impact upon the status of the medical profession and upon the kind of service to be offered to the future patient, the doctors of this country will have to take the final decision whether or not to go into the Service prepared with a clear conscience to make it work. If discussions on Regulations are so unsatisfactory as to make the completed picture of the new National Health Service Act repellent to the medical mind, then the medical profession will be able to give a final "No" to the Minister of Health completely satisfied that it had withheld its answer until the intentions of the Minister were fully revealed.

This is one of the two alternatives with which the profession is now faced. What will be the position if the Negotiating Committee is instructed not to enter into discussions with the Minister on the Regulations and Orders of the National Health Service Act? The Minister, it is true, could proceed to make these Regulations and Orders with, presumably, the advice and assistance of the minority in favour of discussions. There can be no doubt, for example, that in this he would have the support of the Socialist Medical Association. He would, however, not have the indispensable support of the constituent bodies of the Negotiating Committee. The answer "No," backed by a substantial majority, would make the Act inoperable, and further legislation would be necessary to secure those principles the medical profession considers to be fundamental to its professional existence. But for the Negotiating Committee to be strongly armed in any conflict that might arise as a result of a negative answer the majority would have to be substantial and firm in its purpose. It is, of course, obvious that if the medical profession was so set against the Act that it felt unable to work under it such a decision would in no sense be illegal or in the nature of a strike. Doctors do not strike. They will always continue to serve the sick public. An Act is not necessary to make them do this. It would simply mean that they would not serve the sick public within the framework desired by the Government of this country. The Minister fully recognizes the right of the individual medical man not to enter the Service, so a decision not to enter into it would be strictly legal and honourable.

What factors are there in the present situation which might lead medical men to refuse to discuss with the Minister of Health the Regulations under the National Health Service Act? It has been said that economic factors will weigh heavily with medical men in the decision they arrive at. It is obvious that economic considerations must count with any man who has to earn his own living. We doubt, however, whether doctors generally would be misled by any favourable economic terms the Minister might propose as an inducement to enter the Service, for the simple reason that, as insurance practitioners know well, a Minister who can offer favourable terms in one year may in another year do the opposite. Nor do we think that medical men will sacrifice what they hold to be important principles for the sake of an immediate return in payment. These principles are set forth in the statement by the Negotiating Committee published in this week's *Supplement*, as well as an analysis of the divergence between the principles and the provisions of the Act. The essence of these principles is contained in the first: "The medical profession is, in the public interest, opposed to any form of service which leads directly or indirectly to the profession as a whole becoming full-time salaried servants of the State or local authorities."

In his speech at Exeter Dr. Dain stated his belief that the Act is part of the nationalization programme which is being steadily pursued by the Government. "What the Minister appears to have done," he observed, "is to have taken the Bill which we had partly fashioned and to have inserted into it the Socialist principles of State ownership of hospitals, direction of doctors, basic salary for doctors, and abolition of buying and selling of practices." Again he said: "We have attributed the importance of our professional position to the freedom we have to be employed by the patient and, in private practice, paid by him, or in insurance practice paid for him, but whether paid by or for the patient we have what is called free choice." Dr. Dain observed that neither the voluntary nor the municipal hospitals had put forward any definite or very strong opposition to the Bill, but it seemed to him that one of the earliest effects of the Act would be that the greater proportion of the consultants and specialists would become to all intents and purposes State servants. "We want," he concluded, "to put into the Act the right of every doctor to come in, and the right of appeal to the courts from the Minister's decision to take us out of the Service; we want removed from the Act the State ownership of hospitals, the embargo on the buying and selling of practices, all direction of general practitioners, and the salary element in general practitioners' remuneration; we want altered the procedure of election on to the councils and committees so that we may nominate our own representatives instead of the Minister choosing them all, and in that way we may curb dictatorship in the Service."

Dr. Dain stressed that "everybody should answer according to his views and his conscience the question framed in the plebiscite." He had been asked why the Association did not give a lead, and said that it was for the Council and for him to give the profession an understanding of the position and for the individual doctor to take the responsibility of decision. For that understanding we would urge

everyone to read his speech, the summary of the National Health Service Act, the criticisms formulated by the Negotiating Committee under the heading of the "Profession and the Act," and the letter from the Secretary of the Association. What the profession instructs the Negotiating Committee to do will be faithfully carried out. The onus for determining what is to be done rests on each man and woman now practising medicine in this country.

PENICILLIN IN INTRAOCULAR INFECTIONS

The application of penicillin to external infections of the eye presented relatively simple problems, which have now been largely solved. The two time-honoured methods of treating the outer eye by drops and ointments are both used. Watery solutions have proved satisfactory, and of the various ointment bases the oculentum base of the *British Pharmacopoeia* (yellow soft paraffin 9 parts, wool fat 1 part) has proved better than many of the newer bases. The cold creams have been disappointing, because they are rapidly dissolved and because some of them tend to be irritating. Now that the imperative need for a buffered ointment base is recognized penicillin ointments have been widely adopted. The concentration of penicillin is a matter of importance, and in the more severe infections the maximum concentration that can be tolerated is generally employed: 2,500 units per ml. for drops and 800 to 1,000 units per g. for ointments. The frequency of application is also important. For example, in ophthalmia neonatorum the best results are obtained by prescribing drops at intervals of one minute for the first half-hour, every five minutes for another half-hour, and subsequently at longer intervals.¹ As for its range of efficacy in the external infections, penicillin is invaluable in purulent and muco-purulent conjunctivitis, in sepsis of the lids, styes, infected corneal ulcers, and to a lesser extent in blepharitis. The immediate results in blepharitis are generally good, but relapses are common, probably because sepsis is only one aspect of this condition. Promising preliminary results have also been obtained in the treatment of trachoma.

The use of penicillin in the intraocular infections presents many complexities. In the usual concentrations for drops and ointments penicillin does not penetrate into the interior of the eye. Intramuscular injection has also proved disappointing, as the drug does not reach the eye in a therapeutic concentration. Ionization presents clinical difficulties which have yet to be overcome, and subconjunctival injection is limited by the irritating effect on the eye of any large quantity of penicillin. In tolerated concentrations the amount reaching the interior of the eye seems to be low and therapeutically ineffective. Moreover subconjunctival injection cannot be repeated as frequently as the rapid excretion from the eye requires. A partial solution of these difficulties, particularly in the case of hypopyon ulcer, has been suggested by Juler,² who applies solid penicillin to the infected cornea. Many observers have advocated the introduction of penicillin directly into the anterior chamber and into the vitreous, but Von Sallmann, Meyer,

¹ *British Medical Journal*, 1945, 1, 903.

² *Brit. J. Ophthalmol.*, 1946, 30, 204.

³ *Arch. Ophthalmol.*, Chicago, 1944, 32, 179.

⁴ *Brit. J. Ophthalmol.*, 1945, 29, 511.

⁵ *Ibid.*, 1946, 30, 134.

and Di Grandi,³ Sorsby,⁴ and Mann⁵ have all found that the eye, and especially the vitreous, does not tolerate such injections.

For these reasons the place of penicillin in the treatment of intraocular infections remained ill-defined until the recent advent of pure penicillin and the application of massive doses of penicillin systemically. In 1944 Struble and Bellows⁶ indicated that a concentration of 1 unit of penicillin per ml. of aqueous could be obtained in the dog by the injection of 12,800 units per kilogramme bodyweight. Town and Hunt⁷ have recently confirmed the possibility of obtaining adequate therapeutic concentrations by massive injections of penicillin, and Town, Frisbe, and Wisda⁸ have shown that experimental infections of the anterior chamber of the rabbit can be controlled by intraocular injections at 3-hourly intervals of 5,000 units of penicillin per kilogramme bodyweight. Further confirmation of the feasibility of controlling infections of the anterior chamber by the systemic administration of penicillin is recorded at page 723 of the current issue of the *Journal* by Sorsby and Ungar, who also obtained partial control of vitreous infections by this procedure. The data they give on the concentration reached in the aqueous of the rabbit after the injection of 25,000 units and of 50,000 units systemically indicate that though an adequate therapeutic level can be reached it is evanescent, persisting for not longer than three hours. When penicillin is given intramuscularly in beeswax there is longer maintenance of the concentration in the aqueous but at a lower level. It is possible that the administration of even more massive doses of penicillin intramuscularly may yield a higher concentration, but the work of Town and Hunt⁷ suggests that this is unlikely. None the less the significant fact is that suitable therapeutic levels can be reached in the aqueous by systemic administration, and it remains only to establish optimum doses and adequate methods of giving the drug. As for the vitreous, Leopold⁹ could not obtain any therapeutic concentration of penicillin by intramuscular and intravenous injections of massive doses of penicillin, nor could he control experimental infections of the vitreous by such treatment. Leopold, however, used only 4,000 units per kilogramme bodyweight, and the higher doses may explain the better results obtained by Sorsby and Ungar. That the control of vitreous infections is not satisfactory is perhaps only to be expected in view of the low vitreous concentrations that even the massive doses employed by Sorsby and Ungar produce. A further increase in dosage may perhaps overcome this limitation, but the outlook is not too promising.

The high degree of tolerance of the eye to pure penicillin makes it possible to inject subconjunctivally at frequent intervals quantities massive enough to reach concentrations in the aqueous which are many times higher than the necessary therapeutic level. These high levels are, moreover, maintained for longer than the lower levels following massive systemic administration. The experimental and clinical results recorded by Sorsby and Ungar show the efficacy of this procedure. Even in desperate cases subconjunctival penicillin was not unsatisfactory; in these circum-

stances a clinically satisfactory result in three out of eight post-operative infections is more significant than the two total losses. Their results in vitreous infections were less satisfactory. A total loss of two eyes was to some extent balanced by a partial control in a third eye, and rather more than a partial control in a fourth eye. It is possible, of course, that the trauma of an intraocular foreign body contributed to the total loss of two out of three eyes with such an injury, but these clinical results and the experimental findings emphasize the gravity of a vitreous infection. Experimentally subconjunctival injections gave adequate control, while other methods were not so satisfactory. In man, however, subconjunctival injections may not be quite adequate, and the possibilities of pure penicillin injected into the vitreous require further exploration. Like other workers, Roenne¹⁰ found that only the direct introduction of penicillin into the vitreous would control an experimental infection. The disadvantage of this procedure is the intolerance of the vitreous to such intervention. Von Sallmann and his associates³ advocated a dosage not exceeding 100 units; Leopold,⁹ on the other hand, found 1,000 units necessary for adequate control. Roenne believes that an injection into the vitreous of up to 500 units is harmless. These observers all used penicillin containing unknown amounts of impurities. That the impurities are responsible for the intolerance of the eye to injections has been suggested by Mann⁵ and seems to be proved by Sorsby and Ungar's finding that the rabbit's eye will tolerate 5,000 units of pure penicillin injected into the vitreous. The control of intraocular infection, and particularly of infections of the vitreous, would seem to lie, therefore, in a judicious blend of massive systemic therapy, with pure penicillin subconjunctivally, and perhaps also direct injection into the vitreous.

WARTIME MENTAL HEALTH

The annual report of the Board of Control for 1945 is the first to be published since the outbreak of war and is largely occupied with a retrospect of the war years.¹¹ It is also the first to be issued under the chairmanship of Mr. Percy Barter, a former secretary of the Board, and it contains a tribute to the work of Sir Laurence Brock, who was its chairman for seventeen years.

In the autumn of 1939 some 25,000 beds were placed at the disposal of the Services and the E.M.S. Four mental hospitals and two colonies for mental defectives were completely evacuated within twenty-four hours, and in twenty other institutions space was released by the transfer of patients. Air raids caused damage and disorganization to over a hundred institutions, and altogether 252 members of the medical staff left for war service. All these disturbances had very little effect upon the death rate in mental hospitals, which was much below that obtaining during the previous world war, though conditions then were not so abnormal. In 1941 the death rate was 33% higher than the pre-war level, but it fell again slowly, until in 1945 the rate was slightly below that for the last pre-war five-year

¹¹ *The Thirty-second Annual Report of the Board of Control for the Year 1945. Part I.* London: H.M. Stationery Office. 1s. net.

average. In 1938 the proportion of deaths to the average number of patients resident in mental hospitals was 66.7 per 1,000, but in 1945 it was only 68.4 per 1,000 notwithstanding the difficulties of the war years. During 1918 the corresponding figure was 203 per 1,000. Details of the 1945 deaths could not be included in the report, but in 1944 the principal causes of death in mental hospitals were diseases of the myocardium, pneumonia, senility, and pulmonary tuberculosis, in that order. Of 8,774 deaths, 113 were due to violence, including suicide, and 363 to general paralysis of the insane. The death rate from tuberculosis was somewhat above the pre-war level.

Admissions to public mental hospitals are governed to some extent by the accommodation available, the facilities provided at different hospitals, and the extent to which out-patient work is developed. They are also influenced by quite external factors, and although it is true that during the war the general community was subjected to abnormal strains which might have predisposed to mental disorder, on the other hand there was full employment and a relatively high standard of living. Admissions in the earlier war years were lower than the average for the pre-war quinquennium. They rose above this average in 1943 and continued to rise for the next two years. The total number of persons under care during 1945 under the Lunacy and Mental Treatment Acts was 146,027 (62,512 males and 83,515 females). There were 33,961 direct admissions, just over half of which were voluntary, and the discharges were equal to 71.7% of the direct admissions. They included 11,271 discharged "recovered" and 10,128 "relieved," as well as 2,801 "not improved." Of those remaining, 130,047 were certified, 15,565 voluntary, and 415 temporary patients.

The number of mental defectives reported to local authorities during the years immediately before the war showed a continuous increase. Between 1930 and 1940 the total reported rose from below 2.0 to over 3.0 per 1,000 population, and those ascertained as "subject to be dealt with" from 1.17 to 2.39. The rise was checked on the outbreak of war but was eventually resumed. The transient fall was due to shortage of staff, transport difficulties, evacuation, lack of beds in certain institutions, and a labour market which enabled defectives who had never before earned their living to become self-supporting. There were 51,768 defectives under statutory care in 1945 and 23,862 under voluntary supervision. The variation in the number of mental defectives reported in different areas is probably not so much a guide to the local incidence of mental deficiency as a pointer to the alertness of the authorities. For example, in one county borough 8.48 per 1,000 of the population were reported, and in another only 1.37. In one Yorkshire county borough the figure was 4.73 and in another only 1.71. There are great differences also between the numbers reported and the numbers ascertained as "subject to be dealt with." In some areas all those reported were apparently "ascertained": in others only half or less than half.

In dealing with reconstruction the report emphasizes the need for substantial reinforcement of the medical personnel of the mental health services. The war has naturally focused attention on the psychiatric needs of Service men and women, and this in turn has quickened appreciation of the needs of the civilian community. Since the passing

of the Mental Treatment Act in 1930 the number of out-patient clinics has increased greatly, but it is apparent that many more are required, and that mental health work is hindered by lack of staff and of proper accommodation.

"With the recognition of the potential importance of these clinics to the mental health of the community and to the efficiency and well-being of the individual the time seems ripe for their rapid expansion so that they can be organized to carry out the wide range of work now regarded as their function. . . Briefly, the functions of an out-patient clinic are to accept for consideration persons referred for psychiatric help, to diagnose the psychiatric disorder, to arrange proper in-patient or out-patient treatment, and to interpret the disorder to persons or agencies who must co-operate in treatment. To achieve this there will be required an adequate staff of psychiatrists, psychologists, social workers, and clerical assistants. If the clinic is to be an all-purpose one there will need to be specialization within it to deal efficiently with the various aspects of the work such as child psychiatry, court work, industrial problems, vocational guidance, teaching and propaganda, and research."

The most important aspect of reconstruction in the mental health service and one with which the Board of Control is now preoccupied is its organization as an integral part of the National Health Service. The Board is considering the rewriting of the Lunacy Code, the recasting and simplification of which is urgently necessary in view of the many and far-reaching modifications which the new health legislation effects in the Lunacy and Mental Treatment Acts and in the Mental Deficiency Acts.

THE MINISTER OF MILK

The Minister of Food recently issued a statement to the medical press on priority milk for invalids.¹ He stated that during the war the amount so allocated remained about 900,000 gallons weekly. By December, 1945, it had risen to 1,200,000 gallons, and since then to 1,300,000 gallons weekly. The Minister concluded that as there was evidence for a 44% increase in invalidism the rise in consumption of "priority milk" must be because of "less strict" medical certification. The Minister then consulted the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council on how to effect economies in the consumption of milk. The M.R.C. Committee appears to have accepted the Minister's view that the increased consumption of "priority milk" is the result of "less strict" certification, because it has advised him that "when the medical profession had been informed of the present situation of the country's milk supplies they would endeavour to effect the necessary economies." The M.R.C. Committee is composed of men able to assess facts in a scientific manner. It is therefore surprising that they should appear to have accepted the Minister's assumption without sifting the evidence. Not one of the members of the M.R.C. Committee is in general practice and therefore without direct experience of the matter they were called upon to judge. The Minister plainly felt in need of scientific backing for what he must have known was a thoroughly unscientific approach. He can have no more grounds for believing that there has not been a 44% increase in invalidism than for concluding that medical certification for milk has become less strict. There are many other factors to be considered, not least among them being the demobilization of 4,000,000 persons from the Forces. The incidence of gastro-intestinal disturbances

¹ *British Medical Journal*, 1946, 2, 661.

he Forces has been a subject for continued comment since 1939. It is clear, in fact, that the Minister of Food finds the medical profession a convenient scapegoat, and it is significant that, knowing the weakness of his case, he made no attempt to consult the B.M.A., the one body which would have been in a position to put him in possession of the facts. At its meeting last week the Council of the B.M.A. took the strongest exception to the Minister's methods and hasty and ill-judged conclusions.

SILICOSIS AND METALLIFEROUS MINING IN ENGLAND

The decennial supplement of the Registrar General reveals that the occupation with the highest standardized mortality ratio (registered deaths expressed as a percentage of the calculated or expected number of deaths in any particular occupation) among males aged 20-65 is "tin and copper mining below ground," with a ratio of 342; the third highest is "other metalliferous mining below ground," 133; and the fifth is slate mining and quarrying, with 168. An account of tin-mining practice in relation to silicosis by Hale¹ which appears in the June number of *Thorax* is herefore of great importance and interest. He explains how the metalliferous lodes in Cornwall are related to the siltas (slate) and to the granite, how the shaft is sunk, and how the ore is removed. In the period 1932 to 1944 one hundred and thirty men were certified as suffering from silicosis, and received compensation. This silicosis conforms more to the classical type than that occurring in South Wales. The miners are exposed to pure quartz, as opposed to a mixture of quartz, mica, clay, coal, and other substances. The lungs present a generalized fibrosis with niliary collagenous fibrous nodulation, and later considerable emphysema with pleural adhesions develops. The skiagraphic appearance is that of reticulation, often starting in the second interspace and going on to nodulation; massive shadows are not as common as in the South Wales coal miners, and appear to be related to reticulation rather than to nodulation. The development of the disease is insidious, but the onset of symptoms is often abrupt, disabling dyspnoea arising in a period of weeks. There may be no evidence of a superadded infection, though its eventual occurrence is the rule; it is sometimes tuberculous and sometimes non-tuberculous. The immediate cause of death is often congestive heart failure or bronchopneumonia.

In all industrial disease the most important thing is prevention; in this case that means the suppression of dust; and great advances have been made by engineers in the invention of drills towards the achievement of this end. Cornwall has made a great contribution, and Cornish tin mining, besides producing valuable raw material, has inspired the Camborne School of Mines to become one of the most famous schools of mining engineers in the world, and Camborne itself to become the centre of the world's rock-drill industry. Treve Holman² has written a historical review of the methods of extracting rock and their relation to silicosis, and he has pointed out that the invention by Leyner in 1902 of the hollow drill, through which a current of water passed, is one of the most valuable aids to preventive and industrial medicine of our time. The latest inventions, which include the tungsten-carbide cutting tip and the apparatus which prevents the drill working without the water's being turned on, may prove to be so effective that silicosis will no longer occur in British mines.

Since it takes an average of ten years for silicosis to develop, at least that time must elapse for us to know for

certain the success that has been achieved by this excellent work; and medical supervision is required during that period for assessment of the results. During the past fifteen years medical supervision under the direction of Craw³ has been carried out in the haematite miners in Cumberland with very great success; in fact, he claims that no miner who has entered the mines in that period has developed any signs of dust disease of the lungs. This has been achieved by careful selection of the men allowed to enter the mines and their repeated examination and routine chest skiagraphy, which among other things ensures that early cases of tuberculosis are identified and removed. The presence of the tuberculous in metalliferous mines has certainly in the past been a very serious matter. Tuberculosis, inextricably bound up with silicosis and often the cause of the abrupt onset of symptoms, is undoubtedly one of the factors predisposing to the development of that disease, which itself favours the development of tuberculosis.

PNEUMONECTOMY IN BABY OF THREE WEEKS

Pneumonectomy has now become a standard operation in thoracic surgery, but the occasions when it is needed in very young children are few, and in infants it is an unusually rare procedure. For this reason the recent report by Gross⁴ of a case of successful pneumonectomy in an infant aged 3 weeks and weighing only 6 lb. 4 oz. (2.8 kg.) is of great interest. It would appear to be the youngest case of pneumonectomy on record.

The baby's breathing was noticed to be abnormal and laboured on the fourth day of life, and during the following days the symptoms gradually increased in severity until dyspnoea became pronounced and cyanosis appeared. The child was admitted to hospital, and skiagraphy revealed a large air-containing tension cyst in the substance of the left lung causing gross mediastinal displacement and compression of the left lung. Operation was decided upon, as it was considered that needling to relieve tension would be of only temporary benefit and might lead to further complications. Pneumonectomy was performed easily by dissection of the individual vessels and the bronchus; in addition to the large cyst several smaller cysts were present. The child made a rapid recovery, and at the age of 6 months weighed 15 lb. (6.75 kg.) and seemed perfectly healthy and normally developed.

A large congenital cyst in the lung at this age is usually fatal, and most cases have been recorded post mortem. Gross is therefore to be congratulated both on his courage in attempting such a formidable operation at this tender age and on the excellent result obtained. It is especially interesting to know that the operation was so well tolerated.

The case is also of interest as an example of true congenital cystic disease of the lung. A histological description is given. Gross quite correctly points out that in many cases, and especially in older patients, it is often difficult or impossible to know whether one is dealing with a true congenital cyst which has become infected or with a condition of bullous cystic disease following upon an infective process in the lung with scarring. Many, however, would not agree with him in his statement that a lining membrane composed of bronchial epithelium, the individual cells of which are ciliated, columnar, and mucus-secreting, positively identifies a cyst as being congenital in origin. True columnar ciliated epithelium of bronchial type can undoubtedly grow into and form a lining of a chronic lung abscess, thus closely mimicking a congenital cyst. In many such cases differentiation from congenital cystic disease is certain on the clinical features and on serial skiagraphy.

NATIONAL HEALTH BILL FOR SCOTLAND

THE PROPOSED NEW SERVICE

The National Health Service (Scotland) Bill was published on Nov. 6 together with a White Paper¹ outlining the proposed new service. The notes that follow are abstracted from the White Paper. It reveals some differences between the Scottish Bill and the English Act, which received the Royal Assent last week.

The Bill provides for the establishment of a comprehensive health service in Scotland. It does not deal in detail with everything involved in the service. It deals with the main structure. Within that structure, further provision will be made by statutory regulations—on lines which the Bill lays down and subject always to the control of Parliament. All the service, or any part of it, is to be available to everyone in Scotland. The Bill imposes no limitations on availability—e.g., limitations based on financial means, age, sex, employment or vocation, area of residence, or insurance qualification.

The service is to be available from a date to be declared by Order in Council under the Bill, probably early in 1948, as for the corresponding service in England and Wales.

The health service is to be financed partly from the exchequer, partly from local rates, partly from the help which part of the National Insurance contributions will give. There are to be no fees or charges to the patient, with the following exceptions: (i) some charges for the renewal or repair of spectacles, dentures, and other appliances, where this is made necessary through negligence; (ii) charges for the provision of domestic help under the Bill and for certain goods or articles in connexion with maternity and child welfare or the special care or after-care of the sick; (iii) payment for additional amenities within the service—e.g., charges for private rooms in hospitals.

General Organization

The Bill places a general duty upon the Secretary of State to promote a comprehensive health service. To bring physical and mental health closer together in a single service, it places the administration of the mental health services under the Secretary of State in the same way as the physical health services, while leaving undisturbed the functions of the General Board of Control for Scotland in regard to the liberty of the subject and the interests of the individual.

For parts of the service organized on a new national or regional basis—i.e., hospital and specialist services, ambulance services, blood transfusion, and bacteriological laboratories for the control of epidemics—the Secretary of State is to assume direct responsibility; but he is to entrust the actual administration of the hospital and allied services to new regional and local bodies established under the Bill. These bodies are to act on his behalf in suitable areas, and they are to include people of practical experience and local knowledge and some with professional qualifications. Special provision is made for the medical and dental teaching which is carried on in connexion with those services. The Secretary of State is also to undertake the provision of the new health centres; but he is empowered to delegate this function to the major local authorities.

For parts of the service organized as a function of local government—i.e., a variety of local domiciliary and clinic services—direct responsibility is put upon the major local authorities, the county councils and town councils of large burghs. They will stand in their ordinary constitutional relationship with the central Department, but their general arrangements for these local services are made subject to the Secretary of State's approval.

For the personal practitioner services both in the health centres and outside—i.e., the family doctor and dentist and the pharmacist—new local executive machinery is created in the form of local executive councils. One half of the members of each of these councils will consist of people nominated by the major local authorities and by the Secretary of State, and

the other half of people nominated by the local professional practitioners concerned. There will normally be an executive council for each of the counties and of the four largest cities; and they will work within national regulations made by the Secretary of State.

To provide professional and technical guidance, there is to be set up a Scottish Health Services Council. This will include people chosen from all the main fields of experience within the service—with various standing committees of experts on particular subjects, medical, dental, nursing, and others.

Hospital Administration and Endowments

The existing premises and equipment of voluntary and public hospitals are transferred to the Secretary of State under the Bill, and he is empowered also to acquire by purchase—where necessary—other hospitals and their equipment which may be required for the purposes of the new service. If in any particular case he is satisfied that the transfer of a hospital is not in fact necessary for the new service he can—with the institution's concurrence—except it from transfer. The general transfer of hospitals includes the present mental hospitals and mental deficiency institutions.

The Bill requires the Secretary of State to entrust the administration of the hospital and specialist services to a specially created regional and local organization. Regional hospital boards are to be set up to act as agents of the Secretary of State for the general administration of hospital and specialist services in their areas. Five such boards are envisaged in Scotland. In turn, to act as agents of the regional hospital boards for the control and management of particular hospitals, boards of management are to be set up, one for each large hospital or for each group of hospitals forming a convenient unit.

The area of each regional board is to be fixed by the Secretary of State in an order subject to Parliamentary review. So far as practicable each area is to be such that the provision of hospital and specialist services in the area can conveniently be associated with a university medical school. Each regional board will be composed of people chosen by the Secretary of State for their individual suitability for the task, but before making the appointments the Secretary of State is to consult any university with which the hospital services in the area are associated, bodies representative of the medical profession, local health authorities of the area, and others concerned including initially those with experience of the voluntary hospital system. The boards are to include some members with experience of the mental health services.

Boards of management are to be appointed by the regional hospital board, in accordance with a scheme drawn up by the regional board in consultation with the university, and approved by the Secretary of State. The scheme will specify the hospitals which are to provide facilities for medical teaching and also the hospitals which are to be grouped for appointment of a board of management. Each board of management is to include members appointed after consultation with the local health authorities of its area, with executive councils for general practitioner services in its area, with the senior medical and dental staff of the hospitals concerned, and with the governing bodies of any voluntary hospitals that are to come under the board. Where a hospital provides medical teaching facilities, the board of management is to include university and teaching staff nominees.

Subject to general regulations and any particular directions the Secretary of State may give, the regional organization of the service will be undertaken by the regional board itself. Within that framework each board of management will be as free as possible in the actual running of their hospital. For example, although all persons employed at the hospitals will be technically employees of the regional boards, boards of management will in fact choose, appoint, and dismiss all staff except certain senior officers; subject to bulk supply arrangements in appropriate cases they will have discretion in the purchase of equipment and supplies; and they will be responsible for maintenance work or improvements at hospitals, short of major extensions or works involving change of the hospitals' functions in the regional service. They will be able to set up committees for particular purposes.

¹ Cmd. 6946. H.M. Stationery Office, Edinburgh. Price 4d.

including house committees for individual hospitals where a group is within their care.

It is intended that the regional boards and the boards of management shall enjoy a high degree of independence and autonomy within their own fields. For the general financing of their hospital services they will look to the exchequer, and they will be given as much financial freedom—by a system of block annual budgets or otherwise—for local initiative and variety of enterprise as general principles of exchequer responsibility make possible. They will also have independent control of the endowment funds entrusted to them. The endowments of each voluntary hospital transferred to the Secretary of State—defined in the Bill to mean, broadly, all its property other than buildings and their contents—will pass, in the first place, to the board of management responsible for the hospital or group of hospitals in which it is included, and the board will hold them in trust exactly as they were held before. The Secretary of State, however, may make regulations providing for some of the property comprised in endowments to be used to discharge liabilities transferred to him from the voluntary hospitals.

The Secretary of State is then required to set up a Hospital Endowments Commission, to operate initially for a period of five years. Its powers may be continued for further periods, and when they finally lapse the Secretary of State may thereafter exercise like powers himself. The Commission is given the duty of reviewing all endowments and making schemes for their future management and application, including in appropriate cases the transfer of endowments from the board of management which received them in the first place to another board of management or a regional board. Schemes may specify a particular purpose for which endowments are to be used, or may enable the board to which they are given to use them for any purpose relating to hospital or specialist services or to research that the board chooses. In making the schemes the Commission is to take into account the spirit of the intention of the founder of the endowment, the extent to which its original purpose is now otherwise fulfilled, and the interests of the hospital service generally.

In addition, regional hospital boards and boards of management are also enabled, under the Bill, to receive gifts or legacies and to hold any property on trust for any purpose relating to hospital or specialist services or research. Such acquisitions are not subject to review by the Commission.

Hospital Staffs

Specialists taking part in the service, whole-time or part-time, will be attached to the staff of hospitals. Part-time participation in the service will not debar the specialists from also continuing any private practice outside the service which individual patients may wish them to undertake. Special provision is to be made by regulations affecting the appointment of senior medical and dental staff employed on the staff of hospitals. In these cases the vacancy is to be advertised, and an advisory appointments committee is to be set up for each occasion. This committee will consist of nominees of the regional board and boards of management concerned; in the case of a specialist appointment, specialists nominated from a national Scottish panel maintained for this purpose; and, in the case of an appointment where the holder is also to have teaching duties, nominees of any university concerned. The committee will select suitable applicants and the appointment will be made from this selection.

The regional boards, or in appropriate cases the boards of management as their agents, will determine the terms of engagement of any staff employed in the hospital service. The Secretary of State, however, is empowered to make regulations governing the qualifications, conditions of service, and remuneration of any or all classes of hospital staff—as of the staff engaged in any other part of the health service. Before making regulations he will consult any appropriate organizations representing the staffs concerned, and it is his intention—wherever appropriate—to use existing, or set up new, negotiating machinery to facilitate those consultations. Existing hospital officers employed on a paid whole-time basis are to be protected, either by being transferred to the new bodies or by compensation if they are not transferred or are re-employed on less favourable terms than before.

The promotion of research, the provision of ambulances, of a blood transfusion service, and of a laboratory service are functions which will for the most part be devolved upon regional hospital boards and boards of management. It is intended to make the fullest use of the motor ambulance service recently set up by the St. Andrew's Ambulance Association and the Scottish Branch of the British Red Cross Society, and also of air ambulance services. The transfusion service in Scotland is at present run by the Scottish National Blood Transfusion Association, and it is intended that this arrangement should continue. The Secretary of State is expressly empowered to provide a bacteriological service, including the provision of laboratories, for the control of infectious disease. This service will be at the disposal of the local health authorities in the discharge of their epidemiological functions.

Medical Education

The Bill leaves untouched existing responsibilities for medical education. But a vital part of medical education is carried out in hospitals, and the Bill therefore places a specific duty on the Secretary of State to make available for this purpose such facilities as he considers necessary to meet all reasonable requirements. Access to facilities for the conduct of research is also essential for the work of a medical school, and a similar duty to provide research facilities is placed upon the Secretary of State. These duties will devolve upon regional boards and boards of management. Every board of management administering a hospital used for medical teaching will include members nominated by the university concerned and by the teaching staff at the hospital; in the case of an important teaching hospital each of these groups may form one-fifth of the total membership. Every regional hospital board will also include members appointed after consultation with the university or universities concerned.

In addition there is to be a Medical Education Committee in each region, to advise the regional board on the administration of hospital and specialist services in the area so far as the provision of facilities for medical education or for research is concerned. This Committee will consist of members appointed by the universities concerned, with an equal number appointed by the regional board; and representatives of other bodies such as the Royal Medical Corporations will also be included where appropriate. Where an officer appointed by the hospital organization for hospital work is also to hold a teaching appointment from the university, the Bill provides that the advisory appointments committee set up in connexion with the hospital appointment is to include a representative of the university.

General Practitioner Services

To arrange these personal health services locally new bodies—to be called executive councils—are to be established. There will be separate councils for the four largest cities and for most of the counties, but some of the counties with smaller populations may be combined for this purpose. Each council is to be so composed that one half of its members are professional—appointed by the local doctors, dentists and pharmacists through their own representative committees in the area—while the other half of the members are to be appointed partly by the local authorities in the area (one third of the executive council) and partly by the Secretary of State (one sixth). The chairman will be appointed by the Secretary of State.

A feature of the personal practitioner services is to be the development of health centres. The health centre system, based on premises technically equipped and staffed at public cost, should afford facilities both for the general medical and dental services and also for many of the special clinic services of the local health authorities, and sometimes also for out-post clinics of the hospital and specialist services. Besides forming a base for these services—e.g., providing doctors on suitable terms with equipped and staffed consulting-rooms in which to see their patients—the centres will also be able to serve as bases for various activities in health education. The Bill makes it the duty of the Secretary of State to provide, equip, staff and maintain the new health centres. He is empowered to delegate this function wholly or partly to local health authorities, but it is not intended to exercise this power widely in the early years of the new service.

Doctors and dentists, who use the new centres while participating in the general personal practitioner service will be in contract only with the new executive councils, and those councils in turn will arrange with the Secretary of State for the use of the centres' facilities by those doctors and dentists. In the case, for instance, of doctors in the general practitioner service the centres will in effect stand in place of the doctors' own surgeries; and the doctors' responsibilities to their patients on their personal lists—e.g., in visiting their patients' homes and in general responsibility for their patients at all times—will be the same whether a doctor practises from a health centre or not.

All doctors are to be entitled to take part in the new arrangements in the areas where they are already practising when the scheme begins. Taking part will not debar them from also continuing to make private arrangements for treating such people as still wish to be treated outside the service instead of taking advantage of the new arrangements, provided that such persons are not on their lists as public patients or on the lists of their partners in a health centre. People will be free to choose their own doctor (including their present doctor if he takes part in the service) subject to the doctor's consenting and being in a position to undertake their care.

All doctors taking part in this part of the new service will be in contract with the executive council for the area in which they practise. The executive council will be required to draw up and publish lists of all general practitioners who are participating. People will then choose their doctor and each doctor will have his own list of the people whom he has agreed to attend. There will be machinery for allocating among the doctors concerned such people as wish to take advantage of the service but have not chosen a doctor for themselves or have been refused by the doctor chosen by them. The relationship of the doctor with any person on his list—i.e., his functions under this part of the service—will then be similar to the ordinary relationship of doctor to patient as it is now known, except that the doctor's remuneration will come from public funds and not directly from the patient.

The Bill itself does not determine the detailed terms and conditions for doctors joining in the service or the doctors' remuneration. These are left to be settled by regulations, and the necessary regulations will be made in consultation with the doctors' professional representatives. It is, however, the intention that remuneration should take the form of a combination of fixed part-salary and of capitation fees. Variations of the fixed part-salary will be possible so as to take account of different circumstances and experience and the differing conditions of practice in particular areas. Supervision allowances can be provided for practices where assistants are employed. It is intended also to institute, under powers contained in the Bill, a contributory superannuation scheme for doctors taking part in the new arrangements.

Actual rates of remuneration for doctors will be determined, in consultation with the profession, in the light of the report received from the Spens Committee. The substance of the Committee's majority recommendations has been accepted by the Government.

Distribution and Sale of Medical Practices

To help in dealing with the needs of under-doctored areas it is intended to adjust the scales of remuneration of doctors so as to provide additional inducement to practise in less attractive areas. In addition, a new body to be called the Scottish Medical Practices Committee, mainly professional in composition, is to be appointed under the Bill to regulate in future the succession to old, or the opening of new, practices within the service. To begin with, an appointed day will be fixed and all doctors then in practice will have the right to have their names included in the lists drawn up by the executive councils for the areas in which their existing practices are. After the appointed day any doctor who wishes either to join the public service for the first time or, if he is already in it, to go and practise in a new area will need to obtain the consent of the Medical Practices Committee. He will normally ask to have his name included in the list of the executive council for the area of his choice and that council will inform the Committee. The Committee may give consent either unconditionally or subject to a

condition as to the part of an executive council's area in which he may practise. They will not be able to withhold consent on any ground except that there are already enough doctors practising in the public service in the area in question. If, when a practice becomes vacant in a particular area, there is more than one applicant for taking it over, the Committee will decide to which doctor the necessary consent is to be given. Before reaching their decision the Committee is required to consult the executive council, which in turn is to consult the doctors' own local representative committee. A doctor whose application to practise in a particular area is refused, or granted only subject to conditions, is given the right to appeal to the Secretary of State.

The above control of succession to, or opening of, practices will apply to all practices which are wholly or partly within the service. It will, therefore, make the sale of the goodwill of such practices inappropriate, and the Bill provides for the prohibition of the sale of such practices in future and for compensation to existing practitioners in respect of the consequent loss of selling values. Regulations will govern the detailed method of apportioning the global sum among the doctors entitled to compensation and the manner and times at which it is to be paid. It is intended that the settling of the apportionment of compensation among the individual doctors shall be left in the main to the profession itself and the Secretary of State will accept any reasonable proposals within the sum available for Scotland. Normally compensation is to be payable on the retirement or death of a doctor, though payment at an earlier date will be arranged where hardship (e.g., through outstanding debts) would otherwise arise. In the meantime interest on the compensation due is to be paid each year to the doctor at the rate of 2½% per annum.

Tribunal for Disqualification

A special Tribunal is to be set up to investigate cases where it is claimed—either by the executive councils or otherwise—that the continued inclusion of any doctor, chemist, dentist, or optician in the lists drawn up by the executive councils would be prejudicial to the efficiency of the service. The Tribunal will have a legal chairman, and will in each case include a member of the same profession as the person whose case is being investigated and one other. Where the Tribunal is satisfied that the representations are justified, the executive council will be directed to remove from the list the name of the doctor, dentist, chemist, or optician, who is given the right to appeal to the Secretary of State. Where the Tribunal so decides a similar direction can be applied to all lists in all areas, with the same right of appeal.

Where the Secretary of State is satisfied, after inquiry, that the services provided by doctors, dentists, or pharmacists in any particular area are not adequate he is empowered to take such steps as he considers necessary to secure an adequate service.

The Secretary of State is empowered to arrange with universities and other appropriate institutions for the provision of "refresher" courses for doctors, dentists, pharmacists, and opticians in the service, to contribute towards the cost of these courses, and to pay expenses of persons attending them.

Local Government Services

The "local health authorities" will be the councils of counties and of large burghs, with provision for combination wherever, exceptionally, this may be found desirable. Co-operation between the local health authority and the education authority providing the school health service, where these authorities are different, i.e., in large burghs, is already secured by section 14(5) of the Local Government (Scotland) Act, 1929, as rewritten by the Education (Scotland) Act, 1945. For most of these services the Bill requires the local health authorities to indicate to the Secretary of State the way in which they intend to carry out their responsibilities, which requires the Secretary of State's approval. Their proposals, so indicated, are to be made known also to the regional boards for the hospital service, to the executive councils for the general practitioner services, and to any voluntary organization which to the local authority's knowledge is working in the same field in their area.

Maternity and child welfare and domiciliary midwifery.—The Bill makes it the duty of every local health authority to make arrangements for the care of expectant and nursing mothers and of children under five years of age who are not attending school and who are therefore not covered by the school health service. The local health authorities are also to be the supervising authorities for the purposes of the Midwives (Scotland) Acts, and are to be responsible as under the Maternity Services (Scotland) Act, 1937, for providing a complete midwifery service for mothers who are confined at home. The midwives are to be employed either by the local health authority itself or by voluntary organizations with whom the authority comes to an appropriate arrangement. In addition to the clinic facilities, medical supervision before, during, and after the confinement will be available through the general practitioner service, but where advantage is not taken of this the midwife will have the usual right—and duty—to call in a suitably qualified doctor in case of need.

Health visiting and home nursing.—It is made the duty of the local health authority to provide for a full health visitor service for all in their area who are sick, or expectant mothers, or those with the care of young children. This widens the present conception of health visiting (as concerned with mothers and children) into a more general service of advice to households where there is sickness or where help of a preventive character may be needed.

Local mental health services.—Local health authorities are to be given responsibility for the ordinary local community care in the mental health service—that is to say, the ascertainment of mental defectives (so far as this is not the function of the education authority) and their supervision when they are living in the community. This part of the service covers also the initial proceedings for placing under care those who require treatment under the Lunacy Acts.

Vaccination and immunization.—Compulsory vaccination is abolished by the Bill, but the date for this change will be fixed later by Order in Council. In future it is to be the duty of the local health authority to provide free vaccination and diphtheria immunization for anyone who desires them. The authority will give doctors who are taking part in the general practitioner service the opportunity of undertaking this work. The vaccines, sera, or other preparations required may be supplied without charge by the Secretary of State to local health authorities and doctors, and the service may, if circumstances demand, be extended to cover vaccination and immunization against other diseases besides smallpox and diphtheria.

Care and after-care of the sick.—Local health authorities are given a new power, and duty where the Secretary of State so requires, to make approved arrangements for the purpose of the prevention of illness and the care and after-care of the sick. This can include such things as the provision of special foods, blankets, extra comforts, etc.

Domestic help.—Under the existing law local authorities are empowered to provide home helps as part of their maternity and child welfare functions and, during the war, this power has been extended by temporary enactments to enable them to provide domestic help in a wider range of circumstances. The Bill makes this power permanent and extends it to cover the provision of domestic help, subject to the approval of the Secretary of State, to any household in which it is needed on grounds of ill-health, maternity, age, or the welfare of children. The local health authority will be allowed to make appropriate charges for this service.

Health committees.—Local health authorities will in future be required to appoint statutory health committees and to refer to them all matters relating to the discharge of their functions as health authorities. The health committees may be authorized to exercise functions on behalf of their parent authorities and there is the usual discretion to appoint by co-option expert members who are not members of the authority itself.

Scottish Health Services Council

To advise him generally on the administration of the health service the Secretary of State is to have beside him a Scottish Health Services Council. The members are to be doctors, dentists, nurses, and other professional people concerned with the different parts of the service, together with people having experience of hospital management, of local government and of mental health services—all of them appointed by the Secretary of State in their individual capacities, but after consultation with the appropriate representative organizations. The new Scottish Council will be free to advise the Secretary of State of its own initiative on any expert aspect of the services, as well as on matters expressly referred to it by him. It will report annually to the Secretary of State, who will lay the report before Parliament—with his own comments, if he wishes

—unless he is satisfied that it would be contrary to the public interest to publish the report or any part of it.

The Secretary of State is empowered also to constitute various Standing Advisory Committees on different technical aspects of the new service. These Committees are not specified in the Bill. They will in fact deal with medical aspects of the service, mental health, dentistry, nursing, pharmacy, and any other matters justifying special advisory machinery. They will deal with questions referred to them either by the Secretary of State or by the Scottish Council and will have direct access to the Secretary of State as well as to the Council.

THE NEW ACT

DR. DAIN'S SPEECH AT EXETER

The Plebiscite: Practitioners' Responsibility

On the day after the Royal Assent was given to the National Health Service Bill Dr. H. GUY DAIN, Chairman of Council, addressed a large meeting of the Exeter Division. Between 150 and 200 were present. Dr. J. D. R. MURRAY, chairman of the Division, presided.

Dr. DAIN, who was received with enthusiasm, spoke as follows: The National Health Service Bill yesterday received the Royal Assent and became an Act and is now the law of the land. We members of the profession are in a position of great responsibility—all of us. On our actions now will depend the form of medical practice in this country for perhaps a long time to come. Under this Act it is proposed to give to every citizen free medical attention in his own home or wherever it may be required, including hospital service, the whole to be provided by the State partly out of taxes and partly out of insurance premiums.

As a medical service its first and most important group of officers must be its doctors, and we who may become its doctors are in a peculiar position. The Government which has produced this Act has refused to talk to us about it. Nothing more stupid can be imagined than to set up a scheme without consulting the people who are to carry it out. It is true that before this Government came in we had prolonged discussions with Mr. Willink, Minister of Health in the Coalition Government, on the form that a national medical service should take, and we got a long way towards agreement with him. Indeed, if the General Election had taken place a few months later we might already have had an agreed Bill in the House of Commons. At the election a Government was returned whose policy was the establishment of a whole-time salaried medical service for the entire community. The new Minister of Health, contrary to Labour Party policy, was charged with housing as well as health, and after taking office he refused to say anything about the medical service problem until he had dealt with housing. We were shut out of conversations with him until the end of last year, when we heard that a Bill was in preparation; then we put pressure on him to see us, and we had two or three conversations, in which he told us that the Bill would be his own production and that he was not prepared to consult with the medical profession as to its form or principles.

Nationalization of Medical Practice

We are now faced with an Act containing certain items of policy of which we have definitely disapproved. The Act is part of the nationalization programme which is being steadily pursued by the Government. What the Minister appears to have done is to have taken the Bill which we had partly fashioned and to have inserted into it the Socialist principles of State ownership of hospitals, direction of doctors, basic salary for doctors, and abolition of buying and selling of practices. None of these additions is likely to be of any value for the public: they will not help to produce a better service in any way; but, of course, they do affect us very materially. From being a profession of independent practitioners we are faced with a scheme which will almost immediately turn us into whole-time or part-time salaried servants of the State.

The Minister has said he is not prepared to give way on any of the things we stand for, and it is for us to look carefully at the Act and at our own agreed principles, and to say whether

we should go forward and discuss with the Minister the details of administration.

What are the effects on the practice of medicine of some of the proposals of the Bill? We have not regarded the ownership of hospitals as being so much our problem as that of the hospitals themselves, and as neither the voluntary nor the local authority hospitals have put forward any very definite or strong opposition to the Bill it has been rather overlooked that from the medical point of view this may be one of the most important factors. When the Minister owns all the hospitals he will not only administer them through a regional body but he will have power to say what are the terms and conditions of service and what must be the nature of the qualifications of the people who work in them. He has power under the Act—and he has said that he will insist upon it—to ensure that no doctor shall work in the hospitals unless he is a member of the service.

Consultants and specialists can hardly practise without hospital beds, and, as I see it, the Act is the end of independent private consulting practice, unless the consultants and their friends are prepared to set up nursing homes all over the country. A modification was made by the House of Lords to the effect that those entitled to treat private patients in private wards must be "either honorary or paid members of the staff." In a State service in which everybody is paid I cannot imagine what meaning is to be attached to the word "honorary," and I think the Minister, perhaps with some amusement, allowed the phrase to remain because it pleased the Lords and meant nothing. It looks to me as if one of the earliest effects of the Act will be that the greater proportion of consultants and specialists will become, to all intents and purposes, State servants.

If this is not Control, what is?

On the general practitioner side there are three special points to be borne in mind. As a first step towards making practitioners Civil Servants they are no longer to be allowed to buy or sell practices. The Minister has made a great deal of this buying and selling as an immoral act, describing it as the transfer of large blocks of patients, which is a complete travesty of the position whereby goodwill only is transferred. And although it is "immoral" for a general practitioner to buy and sell his practice it is not "immoral" for the consultant or for the dentist similarly to buy and sell. The general practitioner has looked to the capital value of his goodwill to provide him with an income on retirement, and, recognizing this, the Minister has said that compensation shall be paid; and 66 millions is set aside as the appropriate amount. It is not expected that more than five millions of this will be required during the first few years, for the capital will only be drawn by the practitioner on his retirement or by his executors at his death. Some provision will probably be made to assist doctors who are experiencing hardship through having borrowed money to buy their practices, but there is no guarantee that every doctor who is in debt will be able to draw the capital value of his practice straight away. There is only a vague statement that the problem will be dealt with.

Interest at 2½% annually is to be paid on the capital value. We tried to impress on the Minister early in the year that it would be a businesslike proposition to pay out the 66 millions straight away, because the Government could borrow money at a cheaper rate than 2½%, but we could not move the Minister. We have to bear in mind in considering this matter that a capital value which was assessed at 66 millions last year may be vastly different in twenty years' time, in view of the downward course of money values.

The Minister has said that it was necessary for the buying and selling of practices to be abolished in order to obtain a better distribution of doctors all over the country, the assumption being that there is an improper distribution to-day. That is not true. Doctors, on the whole, are not badly distributed. The Central Medical War Committee register has shown that in the areas where there appears to be an undue number a liberal discount has to be made for retired doctors and doctors who are themselves invalid and less active. The distribution of active doctors cannot be learned by taking the total number of doctors in a locality and dividing it into the population. It would be perfectly easy for us through our own organization to distribute the doctors quite fairly about the country without the Minister having the power to direct them.

The Act says that every doctor in practice on the appointed day—presumably April 1, 1948—can stay where he is, but that anyone coming into practice after that date will have to obtain the requisite permissions before he is allowed to settle in any area. Even though doctors in established practice are not liable to be moved, yet if they wish, for domestic, economic, or other reasons, to change their areas after the appointed day, they will have to obtain the permission of the executive councils in the area which they propose to leave and the area in which they propose to settle. If that is not putting us under control or direction I do not know what is.

Dictatorship

Next, the method of payment. We have attributed the importance of our professional position to the freedom we have to be employed by the patient and, in private practice paid by him, or in insurance practice paid for him; but whether paid by or for the patient, we have what is called free choice. So long as we are paid in proportion to the people we serve we retain that freedom. Those of us who have been in national health insurance practice have been quite unconscious of any restriction on our freedom. We declare that in a service for the whole community that same position should be maintained. Directly we begin to be paid even a basic salary we recede from that position, because, instead of our whole interest lying with the patient, a second interest is introduced in the form of the body which employs us or pays us a salary. An amendment passed by the House of Lords that general practitioners should be paid only by capitation fee was rejected by the House of Commons and has been taken out of the Act, the Minister insisting that it is of first importance to him that doctors should be paid, at any rate partly, by salary. You will be aware of the terrible penalties which have been inserted in the Act to ensure that goodwill is not sold twice over—to the State and to somebody else afterwards—and of the difficult position which the abolition of buying and selling of practices will create. It means that all partnerships which depend upon shared receipts and all assistants' agreements will be at an end. It will be necessary for the retiring practitioner to be extraordinarily careful in selling his house, which, though it may have been built or adapted as a doctor's house, must not command on that account any excess value which goes into the practitioner's pocket.

The Act, of course, in parts is good. It does contain one of the things for which we have asked for a long time—a proper organization of hospitals, whereby they do not act as individual units but are to be brought together in regions, based if possible on university centres, so that a more even standard of service is obtainable in remote hospitals. We have obtained representation on all the various committees which control the medical services. We argued with Mr. Willink on that point, and largely the new Act does not interfere with that, except that in every committee or council the Minister has complete control, with power to appoint its members and alter its constitution. The utmost concession we obtained is that the Minister would consult with us before making the appointments. He is not compelled to accept our advice. We had hoped that the Minister would appoint on our nomination, a method of setting up committees which has been accepted under many other Acts of Parliament, but here the Minister takes complete power.

By these powers he becomes the complete medical service dictator. He may use his powers beneficially, but we have seen a number of Ministers of Health during the last twenty years and we know that the wisdom or beneficence of one Minister is not necessarily inherited by his successor. During the passage of the Bill through the House of Commons he opposed every attempt to limit his powers of appointment by saying that it was essential for the flexibility of the service that he should be able to make modifications where he thought necessary in the composition of these bodies without having to go back to Parliament. That was an excuse but no sound reason for departing from the position that we should have the right to nominate for the Minister to make his appointment.

A Vital Decision

What is now our position? A Special Representative Meeting early this year declared by 214 votes to 2 against control over doctors concerning choice of area of practice, by

10 to 29 against State ownership of hospitals, by 229 to 131 in favour of retaining the right to buy and sell practices, and by 209 to 8 in favour of the capitation fee method of payment. That is the policy which through your representatives you have laid down and which your Council is endeavouring to carry out. From to-day we are faced no longer by a Bill which may be altered but by an Act of Parliament. The Representative Body decided that as soon as the Bill became an Act a plebiscite should be taken of the whole profession to find out their opinion on the importance of the principles. If we think that the Act is so dangerous that we had better not proceed to discuss regulations, that the principles set out in the Act do not conform to our ideas of what is necessary to the freedom of medicine in the future, we shall indicate it in the plebiscite. On the other hand, if we think that the risks I have set out are exaggerated, that the Act will really make very little difference to us, and that the non-acceptance of our principles is not fundamental, then we shall tell our representatives to go and talk with the Minister on the details. Even supposing you answer "Yes" in the plebiscite you will be given a further opportunity of saying whether or not you wish to enter the service.

At the moment the Council is bound by the decisions of the Representative Meeting. What we are anxious now to secure is an answer in the plebiscite from every member of the profession. No greater calamity could happen to the negotiators than to find that only half the profession had taken the trouble to answer the question:

Do you desire the Negotiating Committee to enter into discussions with the Minister on the Regulations authorized by the National Health Service Act? Please answer YES or NO.

Excursion into Economics

Before saying anything more about the plebiscite I have a few words to say on the economic aspects. What are the prospects? The Spens Committee has reported that in 1938 doctors' incomes were on the whole too small and that they should have been increased by a certain amount. Starting from the lower incomes up to £1,200 a year net, the increase should have been roughly £200 a year. The capitation fee for insured persons paid at that time was 9s., and it was shown by doctors' returns that all other patients put together—private patients, club patients, etc.—were paying their doctors at the rate of 14s. a year; and, of course, we all know that the private patient was not requiring anything like the same amount of services as the insured patient. We asked accordingly that the insurance capitation fee should be adjusted in accordance with the Spens Committee findings, but the Minister was not prepared to discuss the capitation fee unless it was linked with the terms in the new service, though we impressed upon him that we represented insurance practitioners only and had no authority to deal with the new service at all. Later we were told that we had perhaps got a wrong impression of what the Minister meant, and were invited again to go to the Ministry: but in further conversations it seemed impossible to get the Ministry to dissociate the two things. The Minister announced that the capitation fee would be 12s. 6d. as from January 1, 1946. You know what has taken place since then, and what followed when the Minister learned that well over 90% of insurance practitioners were likely to put in their resignations. We are going to talk over these matters next week at the Ministry's invitation, and we shall get down to discovering what the Spens Report means in terms of capitation fee for national health insurance practice alone.

But these proceedings are very sinister. If at a time when we are only half-embroiled with the Minister and only half the population are at stake we have to resort to what may be called brute force in order to make the slightest impression on the Minister and his department, what hope is there when all are in it? The action of the department has been most illuminating—and most depressing.

Altogether it seems to me quite unlikely that, however we are paid in the new service, we shall obtain as much as from our present practices, which are partly insurance and partly private, and I see no reason why we should go into a service and be less well paid for it than we are to-day, when our services are sought by people as private individuals.

We have to take the 9s. pre-war capitation fee, plus 6d. added on the introduction of persons with incomes up to £420 a year, and to this we have to add, in the first place, the amount by which, according to the Spens Committee, doctors' incomes were inadequate in 1938. We claim that the inadequacy must be ascribed to the insurance side of the practice, because here a fixed fee operated which could not be adjusted according to economic circumstances. The average of this addition over the whole range of incomes is equivalent to £170 per 1,000 insured persons, or about 3s. 4d. per insured person, bringing the capitation fee to 12s. 10d. To this has to be added a betterment figure for altered values since 1938. When we talked with the Government over the compensation proposals—I agree now that it was a mistake to have talked at all—a figure of 22% was agreed to as reasonable, but I have had placed in my hands this week a report by an economic expert—the first in the country, for we always employ the best experts we can, believing in expert advice ourselves—and he says that the betterment figures now on 1938 values should be 45%. It is obvious that if that percentage had been taken when assessing compensation values 66 millions would not have been nearly sufficient. Therefore to the figure of between 12s. 6d. and 13s. we have to add 45% for betterment, showing that the 15s. of which so much has been made in the press has no relevance. My point in entering into all this is only to show the risks we run if we go into a service in which we are paid by salary and are in the hands of the State so completely.

The Plebiscite

I come now to the plebiscite. All members of the profession will shortly receive, together with a summary of the Act and a statement of conflict between the conditions laid down in the Act and our own principles, a form requesting an answer "Yes" or "No" to the question whether it is desired that the Negotiating Committee should enter into discussions on the regulations.

(Dr. Dain read here the statement "To every member of the profession" which appears on the form.)

The last sentence in that statement reads as follows: "Implicit in such a negative vote by general practitioners and the staffs of voluntary hospitals is an undertaking, if so advised by the Association, not to enter the new service." This has been framed having in mind medical officers of health who are already employed in a local authority service. We want to make it clear that the medical officer of health who is opposed to this new service because it contravenes the principles which the profession has laid down may properly vote "No" without being expected to resign his office, a thing which it would not be feasible or proper for us to ask him to do.

The difficulties with which some practitioners may be faced are fully realized, and action is being taken by the Association to deal with them. At the meeting of the Council yesterday we appointed a committee to consider the use to be made of the money at our disposal to meet cases of hardship. We are well aware of the difficulties of men in their forties with children to educate, and the handicap which it might be to some of them if all contract work were stopped consequent upon the resistance of the profession to the new scheme. We have very substantial sums in hand. If we wanted to do so we could to-morrow morning spend up to a million pounds, and there need be no doubt whatever that if the need becomes obvious it will be met. We are ready for action, and we put it to the members of the profession to-day that they need not be embarrassed in their decision at this critical moment because of financial considerations. We recognize, of course, that if it came to a fight we must all suffer some loss, but as it is true that, for the country as a whole, two-thirds of our incomes comes from private practice and other sources, and only one-third from National Health Insurance, it is not a question of the whole of the income of any person stopping suddenly. It was the view of a number of members at the Council yesterday that whatever happens will have to happen fairly quickly, and it is not reasonable to suppose that we shall have to prepare for a long and exhausting struggle. The Minister is under an obligation to maintain a service to the insured community, and if he is unable to put something in its place because of our opposition to the new service it is almost certain that the insurance medical service must continue.

We are anxious that everybody should answer according to his views and his conscience the question framed in the plebiscite. I am asked why the Association does not give a lead, why I myself as Chairman of Council do not give a lead. It is for the Council and for me when I get an opportunity to give you an understanding of the position so that you may take the responsibility of decision. It is your responsibility, and what the profession says will go. We want a reply to the question uninfluenced by any such consideration as to whether you may be left in the lurch or whether if you stand out your neighbours may take your place. You need not be afraid of being left in a small minority. There are no spare doctors; there are not enough to go round even in a small town.

I am asked what is my own view. The situation is entirely in our own hands. We have just learned that a strong and concerted action will force the Minister to do something which he was entirely unwilling to do. The threat—it was no more than the whisper of a threat—that insurance practitioners would resign if he would not agree to implement the Spens Report brought him to heel at once. Here we have an opportunity of saying that we will not take any part in a service that does not concede our principles. Why should we not get our principles accepted as well as the conditions of service? The conditions will have to be argued afterwards anyhow. Why not insist on our principles being established, by an amending Act or whatever it may be, before we agree for a moment to talk on terms and conditions? We should be no worse off; indeed we should be infinitely stronger in talking about terms and conditions if we had first by our own efforts secured the acceptance of our principles.

Dr. Dain's address was frequently applauded, and there was prolonged acclamation at the close.

Various Questions

Asked whether it was expected that retired practitioners should answer the plebiscite, Dr. Dain said that he certainly expected them to do so. The answers would be analysed in age groups. If a retired practitioner had not the same interest in events, he had the knowledge of his profession and of the validity of the principles they sought to establish.

Another practitioner was anxious that nothing should be done which might be construed as against the law. Dr. Dain replied that the profession was perfectly free to decide not to enter the service. They would be doing nothing against the law in deciding not to take part in it. They had the right to stay out, though they had not yet succeeded in obtaining the right to come in.

A reference was made to the reported satisfaction of consultants with the Act. Dr. Dain said that consultants must surely regard it as unsatisfactory to have no beds under their control which were not State-owned beds. To another question he replied that the Act laid down that the Minister might determine the qualifications of the people working in the service. Though it was not specified that this applied to doctors specially any more than to nurses or hospital porters the fact remained that the Minister had power to decide a qualification which was different from that set up by the General Medical Council. In one instance it was stated specifically that a general practitioner must not do midwifery unless his qualification was approved by the Minister. "We want that out, of course, among other things, but that is the dangerous position that he by this Act has the power to decide what shall be the qualifications for different jobs."

At the request of Dr. Roper, Dr. Dain gave a brief account of the position of State medical services in the Dominions, and referred especially to the satisfactory position in South Africa, where the South African Medical Association set up a committee to advise the Government, and the Government had appointed the chairman of that committee to be chairman of the Government committee to carry out the service.

Dr. G. Lowe, in proposing a vote of thanks to Dr. Dain, said that he, like others, had made criticisms of B.M.A. leaders, but he unhesitatingly withdrew them. In his addresses, in various parts of the country and to the Representative Body and in his work on the Council and elsewhere Dr. Dain had proved a splendid leader. In a quiet and unassuming way he had marshalled the facts, of which he had a complete mastery. The

way in which he and other B.M.A. leaders had acted during this long period of controversy excited his boundless admiration. They had always been careful to consider the wide interests of the public. Bureaucratic control was no more in the interests of the patient than in those of the doctor. The profession had been forced into this fight against its will. I leaders had been brushed aside as stupid children. They had not been allowed to co-operate in the building up of a service about which they ought to know something, at least as much as an erstwhile miner, a trade union leader, and a member of the present Cabinet. He called for 100% backing of the B.M.A. in this vital struggle.

Dr. DAIN, in reply, repeated the things they really wanted.

"We want to put into the Act the right of every doctor to come in, and the right of appeal to the courts from the Minister's decision to take us out of the service; we want removed from the Act the State ownership of hospitals, the embargo on the buying and selling of practices, all direction of general practitioners, and the salary element in general practitioners' remuneration; we want altered the procedure of election on to the councils and committees so that we may nominate our own representatives instead of the Minister choosing them all, and in that way we may curb dictatorship in the service."

These points again were heartily cheered, and the meeting ended.

Correspondence

The Plebiscite

SIR,—Permit me to express my profound admiration at agreement with the fine, robust letter from Dr. Alfred Co (Nov. 9, p. 707). One can only hope and, I might well add, pray that his stirring and powerful appeal will secure the unanimous support of the profession which he has so splendidly served all his life.—I am, etc.,

London, W.8.

FREDERICK MENZIES.

National Health Service

SIR,—I have followed the correspondence on the proposed National Health Service appearing in your columns and would like to submit the following observations. The Bill, soon to become law, contains many provisions that are good; and the scheme no doubt appeals in various ways to some individual members of the many sections of our profession. Thus the young doctor will welcome the prospect of not having to buy a practice; others will look with favour upon a certain security of tenure, while the young man anxious to specialize will see in it a chance to acquire and practise a specialty without enduring years of penury. But surely these considerations are really beside the point. The kernel of the matter, as far as the profession is concerned, is centred in this business of control. Initially, the conditions of service may appear rosy, but we will make these conditions or alter them as time goes on. If we find regulations concerning salaries or hours of work not to our liking to whom shall we appeal for redress? To government and control of hospitals and of the doctors will be in the hands of the nominees of the Minister.

Let each one in our profession, specialist or general practitioner, examine individually this aspect of the Bill as far as he himself is concerned. Recent European history has shown that the Führer, once elected, quickly entrenched himself behind his Gauleiters and Gestapo. As this matter of control over shadows the other provisions of the Bill, I consider that it is on this issue that the B.M.A. should mainly base its propaganda so that no doctor could afterwards say that he was left in ignorance by our Association.

As I have said, the Bill has many good points, but, unlike some of your recent correspondents, I am only as enthusiastic as one free from any illusions can reasonably be expected to be.—I am, etc.,

Consett, Co. Durham.

K. M. MACDONALD.

Vasodilatation

There is considerable evidence of the outstanding value of Cardophylin in producing vasodilatation. The coronary vasodilatation is manifested in an increased coronary blood flow and a beneficial effect on the myocardium; the renal vasodilatation is indicated by the powerful diuresis, while its antispasmodic action appears to be largely the result of the bronchodilatation induced by the drug.

3. Adsorptive power made greater than that of other commonly used adsorbents.
4. An overdose is harmless.

Formula—Magnesium Trisilicate $2MgO \cdot 3SiO_2 \cdot nH_2O$, 91%; Magnesium Hydroxide, $Mg(OH)_2$, 9%.

SIMULTANEOUS IMMUNISATION now possible against DIPHThERIA and PERTUSSIS

Most parents responding to the campaign in favour of diphtheria immunisation readily agree to the inoculation of their children against whooping cough at the same time. Simultaneous prophylaxis against both infections can now be achieved with Diphtheria Prophylactic A.P.T. plus Pertussis Vaccine (alum-precipitated), introduced by Glaxo.

This preparation contains in each 1 cc. at least 1×10^8 diphtheria prophylactic and 20,000 million *H. pertussis*. Administered together, each antigen enhances the effect of the other. One course of three injections (0.5 cc., 0.5 cc., and 1 cc. at intervals of four weeks) condenses the immunisation procedure into a conveniently manageable span. Immunisation at 4 to 6 months of age with this new injection of 'combined antigens' gives subsequent protection over a period of child life in which diphtheria and whooping cough can be most deadly.

MERSALYL B.D.H.

(Injection of Mersalyl B.P.)

The use of Mersalyl B.D.H. should constitute the primary treatment whenever it is necessary to induce prompt or prolonged diuresis. Supplementary treatment, when necessary, may be varied according to the individual needs of the patient. In cases in which there is cardiac involvement, digitalis may be given collaterally. Debilitated patients who may be unduly susceptible to toxic effects of mersalyl should be given Vitamin C B.D.H. to minimise toxicity and to augment the diuretic effect. Patients with liver involvement should be given Dehydrocholin B.D.H. in order to prevent hepatic injury by the mercury compound and, as in the case of vitamin C, to increase the diuretic effect. Further details will be gladly supplied on request.

London Medical Exhibition.—Members of the medical profession will be welcome at the B.D.H. Stand No. 140.

Milk Priorities

SIR,—The Milk Rationing Scheme is too valuable to be allowed to break down for administrative reasons. If general practitioners had been consulted earlier, the present position need never have arisen. The problem is not one for scientific experts, but for practitioners. In my view, the causes of "lax certification" are the extreme vagueness of some of the categories for priority; the absence of other categories; the recognized abuse of the "children's milk" in a substantial number of cases; and the fact that there is no effectual equality in the basic ration as between some groups of consumers and others. It is a fact that some of the "children's milk" is either being given away or else being sold at a profit. It is a fact that in larger families (above four persons) and in hotels, etc., the ration is adequate for the simplest needs, but it is hopelessly inadequate in families of one or two. Since these facts are generally known, it is almost universally felt that the present scheme is "unfair." So long as the arrangements are felt to be unfair, means will be found to evade them.

In my opinion, the following changes should be made: category 2c should be abolished (dyspepsia); "colitis" should be replaced by "ulcerative colitis"; "gastric, etc., ulcer" should receive a priority for six weeks only (but see below). A ten days' priority (after the first three days of illness) should be given to industrial workers who are ill in bed. It should not be given to the "injured or to short-period surgical cases." In all cases in which the doctor in charge thinks that effectual treatment requires a supply of priority-milk, an independent supporting certificate (e.g., from the M.O.H. or his deputy; from hospital consultants or [as has been suggested] from specially appointed practitioners) should be required. I regard it as essential that a category should be added so that the aged can receive more milk than they do at present. Every aged person suffers from "dyspepsia." This point might be met by increasing the basic allowance for small families of one or two persons.

Steps should be taken to "take the profit" out of the illicit sale of the children's milk. It seems to me that the cost of the milk used in a family of children should be made a direct charge upon the "family allowance." This could be done by making a charge for the second half-pint of the "subsidized milk allowed to children." Lastly, all milk given to children at school should either be drunk in the presence of a responsible person, or else collected (sterilized, if necessary, by re-canning) and either sent to an institution or returned to the supplier next morning.—I am, etc.,

Worcester.

HOWARD E. COLLIER.

SIR,—In the announcement issued by the Ministry of Food on Oct. 29, quoted in the *Journal* of Nov. 2 (p. 661), the Minister omits one of the main causes for the increased demand for milk in the United Kingdom. It is that from Aug. 6 milk in publicly provided schools and in private schools has become free to the tune of one-third of a pint per scholar daily. In certain special schools the amount permitted free is two-thirds of a pint. Whereas the consumption of milk in schools varied considerably from place to place before this arrangement was made, I think it will now be found that the consumption approaches nearly 100% of the school population. This free milk is in addition to the extra milk obtainable on the juvenile ration cards. Thus, children may obtain substantial supplies of extra milk from two sources while many elderly and frail people have to be content with milkless days. No one grudges children as much milk as they like provided there is enough milk to go round. It is however arguable, with due respect to the Government experts, that most boys and girls under the age of eighteen can and do eat and digest any ordinary food, whereas the elderly, the frail, and the invalid cannot. Before the Minister blames the medical profession for lax certification, he should put his house in order by reviewing drastically the whole system of milk distribution in this country.—I am, etc.,

Exeter.

G. B. PAGE.

SIR,—For some time I have been of the opinion that a considerable economy in our very restricted milk supply could be effected by reducing the quantity of milk allowed in the Category 2c to half a pint daily. Many cases of mild dyspepsia

cannot possibly manage on two pints of milk weekly, but could make a fairly comfortable diet on three and a half pints weekly. This would save three and a half pints weekly, as these cases now must have seven pints or be refused priority. Doctors, also, should be permitted to state the time for which all priorities are needed. One month is much too short for cases of thyrotoxicosis, nephritis, etc., and monthly repetition of these certificates wastes time. While on the subject of certification I should like to know whether some means of reducing this intolerable burden cannot be devised.—I am, etc.,

St. Leonards.

ANNE BEATTIE.

SIR,—The public scandal of milk "priorities," now a subject of contemptuous comment in the lay press, will continue until something is done to stem the spate of medical certificates. Abolition of the ridiculous categories of "dyspepsia" and "colitis" might help. A woman to whom I refused a certificate which she demanded merely on the grounds that she "hadn't enough milk for the cat" informed me, subsequently, that she was able to obtain milk from a neighbour whose "doctor is not so strict and gives her milk certificates for anything." This is not, I have very good reason to believe, a unique case.—I am, etc.,

Hove.

SIDNEY B. DEPREE.

SIR,—The Minister of Food has announced that medical certificates for priority milk supply to invalids will be disregarded if dated before Nov. 3. He excuses this dictatorial step by saying that medical practitioners have been granting more of these priority certificates in the recent past than they did during the earlier phases of the rationing scheme. It should be pointed out that doctors can only issue such certificates on a prescribed form, and only when they can certify that a patient is suffering from a definite condition on the schedule of diseases drawn up by the Ministry of Food. The obvious inference is that the Minister of Food does not accept the honesty of the doctors who have to issue these certificates. He has virtually stated that he does not put any value on certificates issued up to Nov. 3. What he should realize is that it is not the standard of medical honesty and integrity that has deteriorated during the war years but the standard of the nation's health. We doctors have stood about enough from him and his kind, and it is about time that we rejected this new idea of his with all its nasty implications. I can say clearly and fairly myself that every patient of mine at present receiving extra milk will continue to do so. I shall reserve the right to judge whether people are ill enough to require extra milk or not, and will certainly not be coerced into any attempt to deny them what is a necessity of life in their case merely to satisfy the whim of a nebulous Food Official. "one dressed in brief authority."—I am, etc.,

Torbart, Argyll.

A. KENNETH YOUNG.

Priority Certificates for Rationed Foods

SIR,—For years past the profession has acted as agents for the Ministry of Food in certifying on form R.G.50 any disease for which a patient could obtain priority rations. This has entailed much labour—unpaid to the extent that, though in theory one might make a charge, in practice I have never heard of anyone doing so. The work is unpleasant in that refusal of a certificate resulted in a disgruntled patient and often a subsequent loss to the practice. It should be noted that any resentment felt is directed against the *doctor*—not the Ministry, who have thus succeeded in shelving the unpopularity rightly belonging to it on to the profession. With the issue of the Ministry's instructions that all cases are to be reviewed an enormous amount of extra work will fall on doctors, with a still larger amount of unpopularity. We cannot refuse to do the work, as to do so would harm such patients as are rightly entitled to priority; but what we can do, and what I urge should be the routine procedure, is to give certificates *not* on form R.G.50, and *not* in the Minister's code, but giving details of the illness from which the patient suffers. This he can take to the Food Office, where the priority form will be issued or refused, so saving the doctor the explanations and arguments for which he has little time and less taste, and the unpopularity for which he is in no way to blame.

One further point: I note that the Ministry state that there is no evidence of increased illness to account for a 44% increase

in priorities. Might one ask where the Ministry get their figures of illness? It seems to me that the returns of deaths, infectious disease, and claims for N.H.I. benefit to which the Ministry have access bear little relation to the volume of actual work done by doctors or the amount of minor ill-health present in the community.—I am, etc.,

London, S.W.1.

ARNOLD HARBOUR.

Work of Government Lymph Establishment

SIR,—My attention has been drawn to the article appearing in the Oct. 26 number of the *Journal* by Dr. H. S. Fremlin in which he describes the work of the Government Lymph Establishment from July, 1898 to June, 1946. It was with considerable surprise that I was unable to find anywhere mentioned the name of Lieut.-Col. W. D. H. Stevenson, C.I.E., M.D., D.P.H., I.M.S. (ret'd.), who was Director of the Establishment from 1930 to 1945 and was thus in charge throughout the strenuous times of the last war regarding which Dr. Fremlin says: "In addition we supplied 750,000 doses to Scotland during the 1942 outbreak of smallpox there, as well as dealing with minor outbreaks in England. Altogether from September, 1939, to May, 1945, over 15,000,000 doses were issued. At one time during the war our reserve stood at over 5,000,000 doses." (The italics are mine.) I know that Col. Stevenson when Director was not only responsible for the supply of lymph but for many years until his death in 1945 carried out many arduous researches for the Government on bacteriological and other issues in connexion with modern developments of vaccine lymph manufacture. It seems scarcely credible that no mention should be made of his name in what purports to be a review of the work of the Establishment up to last year.—I am, etc.,

Cambridge.

S. R. CHRISTOPHERS.

SIR,—In reading the article by Dr. H. S. Fremlin (Oct. 26, p. 613) I was surprised to see that no mention whatsoever was made of the great work done either by the late Lieut.-Col. W. D. H. Stevenson, who was the Director of the Government Lymph Establishment from 1930 till his death in 1945, or by his colleague and second-in-command, Dr. G. G. Butler. On those two more than anyone else fell the great burden of meeting the tremendous demands for lymph from 1939 onwards, which Dr. Fremlin has described; and yet Dr. Fremlin writes "we supplied," etc., and "our reserve," etc., which, to those who do not know the facts, would suggest that he with his colleagues—unmentioned except for Mr. Sutton—had been responsible for this work. Honour to whom honour is due, and since, as I understand, his own good work ended in 1930, Dr. Fremlin would probably like to make the situation more clear than he has done in the latter part of his article, which presumably was intended only to stress the value of refrigeration in storing lymph during the war.—I am, etc.,

Leitchworth.

H. H. KING.

The *Xenopus* Test for Pregnancy

SIR,—Prof. Hogben's letter on the *Xenopus* pregnancy test (Oct. 12, p. 554) calls for a reply not only because it contains several gross misrepresentations of the true facts but also because many of the claims made in support of his contention are irrelevant. He writes: "Zwarenstein and Shapiro enjoyed the hospitality of my laboratory during their visit to London in 1933. We then demonstrated to them both the results of our pregnancy tests. . . ." In actual fact, Shapiro visited London for the first time in 1936 and Zwarenstein can state unequivocally and with certainty that neither Hogben nor Bellerby nor any other member of Hogben's department gave him any information whatsoever either verbally or by demonstration about pregnancy tests on *Xenopus laevis* during the time he was enjoying the hospitality of Hogben's laboratory in London in 1932-3. It is quite clear that Hogben's recollection of events does not correspond with the facts. In any case, if Hogben had communicated any such information about the test due and adequate acknowledgment of any private communication would, as a matter of course, have been made in our preliminary announcement of the test in October, 1933. The unquestioned priority for our description of the test is established by our communication to the Royal Society of South Africa on Oct. 18, 1933, when we stated the number of tests we had performed. This communication was actually

abstracted in *Nature* on March 3, 1934, p. 339, and therefore appeared in England before Bellerby's letter to *Nature* on March 31, 1934. English readers were, therefore, in a position to have read our account before Bellerby published his own letter to *Nature*, in which he did not state the number of tests he had made.

Hogben's assertion is further controverted by the fact that the procedure of performing the test as described by Shapiro and Zwarenstein (1933) differs in all major respects from that described by Bellerby (1934). Shapiro and Zwarenstein employed the alcohol method and Bellerby, in his subsequent communication, described an acetone method for the preparation of urine extracts. According to Bellerby, actual extrusion of ova must occur in at least five of ten test animals before a positive diagnosis is made. Shapiro and Zwarenstein, on the other hand, regarded ovulation in *any one* of several test animals as a positive reaction. All subsequent work, by investigators all over the world, amply confirmed the accuracy of the standard laid down by Shapiro and Zwarenstein. Acceptance of Bellerby's criterion for a positive reaction would have led to many and serious errors in diagnosis and would have made the test valueless as a test for pregnancy. It is significant that no one subsequently adopted Bellerby's standards for a positive reaction.

It is interesting, at this stage, to recall the reasons which led Prof. Crew to suggest the association of Hogben's name with the *Xenopus* pregnancy test. They have nothing in common with those attributed to Crew by Hogben. Crew wrote (*B.M.J.*, April 15, 1939, p. 767): "I owe much to the willingly given help of Professor Hogben, now of Aberdeen, in whose laboratory in Capetown it was first shown that this anuran might with advantage be used for this particular purpose. I accordingly propose to refer to the biological test for pregnancy in which *Xenopus laevis* is used as the Hogben test." The statement that *Xenopus* was first used for pregnancy diagnosis in Hogben's laboratory in Capetown is incorrect, even according to Hogben's own account of the history of the test, and since this major assumption is incorrect a sense of gratitude would appear to be an inadequate reason for Crew's proposal.

The lengthy discussion about a captivity effect in Hogben's letter does not affect the point at issue, which is whether or not pregnancy urine can produce ovulation in *Xenopus*. No claim to the authorship of this test can be sustained unless the authors have been the first to describe such a reaction, and Hogben in his letter concedes our priority. We disapprove of an eponymous nomenclature for tests of this kind and have always regarded our own contribution as an obvious application based on the fundamental discovery of Aschheim and Zondek. Consequently, from the outset, we have preferred to call the test the *Xenopus* or frog test.—We are, etc.,

H. A. SHAPIRO.

H. ZWARENSTEIN.

University of Capetown, South Africa.

Nomenclature of the Rh Blood Types

SIR,—In a recent article published in this *Journal* (June 29, p. 982) I described my latest improved nomenclature for the Rh-Hr blood types. The nomenclature proposed was devised in order to emphasize the analogies to the scheme of the four Landsteiner blood groups, so that the eight Rh types were designated as rh, Rh', Rh'', Rh'Rh'', rh₀, Rh₁, Rh₂, and Rh₃, respectively. This has caused some confusion to clinicians, who sometimes mistake the designation rh₀ for rh. For this reason, and because Rh₀ is the most important antigen clinically, so that for practical purposes when testing patients' bloods of types Rh', Rh'', and Rh'Rh'' should all be considered Rh-negative, it is proposed to make a slight but important change in the designations which may help to clarify the subject further for the uninitiated. Under this slightly changed nomenclature the three Rh blood factors are now designated as Rh₀, rh', and rh'', respectively, the capital letter being reserved exclusively for the factor Rh₀ in order to emphasize its special position and clinical importance. The eight Rh blood types now become: rh, rh', rh'', rh'rh'', Rh₀, Rh₁, Rh₂, and Rh₃, respectively. The new designations also have the advantage that they remove the danger of confusing the prime sign and the figure "one" in the superscripts, because the use of capitals and small letters removes any danger of ambiguity.

With respect to the reactions of the three types of Rh antibodies, it is now easy to remember that standard anti-Rh, or anti-Rh₀, reacts with Rh₀, Rh₁, Rh₂, and Rh/Rh₂, but not with rh, rh', rh'', or rh'rh''. On the other hand, anti-Rh' reacts with all bloods containing factors Rh₁ and/or rh'—that is, types rh', rh'rh'', Rh₁, and Rh/Rh₁, respectively—while anti-Rh'' reacts with bloods containing factors Rh₂ and rh''. For clinical purposes, patients of types rh, rh', rh'', and rh'rh'' are classed as Rh-negative, but for use as donors only individuals of type rh should be selected.—I am, etc.,

ALEXANDER S. WIENER, M.D.

Serological Laboratory, Office of the
Chief Medical Examiner of New York City.

SIR,—To one who has been obliged to acquire his knowledge of the blood group Rh from published papers, Prof. D. F. Cappell's clear exposition (Oct. 26 and Nov. 2) is most helpful. Nevertheless I raise my hand in almost a last salute to the members of the Ayrshire Division of the B.M.A. if the paper was read to them as published. It would seem wise to support fully the use of the letters CDE. Fisher's terminology for the elementary antigens is neat and informative. But I beg that these sufficiently complicated factors should be capable of being as clearly and easily indicated in speech as in writing. Fisher suggests that the antisera should be denoted by Greek letters. Would it not be wiser to use Greek characters for cde? Would this really be too "troublesome for many workers"?

In accordance with Prof. Cappell's suggestion the 'antisera should be indicated in the simplest way by the use of "anti" before the English or Greek letters denoting the antigens with which they react. This should also be the invariable custom in describing the antisera of the ABO and MN groups. Further, it would seem advisable to indicate the alleles, whose discovery at the CDE loci is confirmed, by means of numerals instead of letters—e.g., C₂ instead of C_w.—I am, etc.,

G. E. W. WOLSTENHOLME,
Lieut.-Col., R.A.M.C.

London.

SIR,—Prof. D. F. Cappell's excellent articles (Oct. 26 and Nov. 2) on this subject prompt me to raise a point about pronunciation. I have heard many otherwise estimable medical men talking about the "Ar-aitch" factor. Now the "rhesus" factor is presumably derived etymologically from the Greek word *ῥῆσος*, and the initial letter is *ῥ* (rho) with the "or" "spiritus asper." If one must contract the word "rhesus" I suggest it is easier to say "rho" than to say "Ar-aitch," and considerably more reasonable.—I am, etc.,

Shipley.

H. S. RUSSELL.

Recent Advances in Anaesthesia

SIR,—Mr. J. Johnston Abraham complains that in my recent article "no reference whatever is made to intravenous anaesthesia." If he would be kind enough to read through my poor effort, he will find a paragraph on this very subject in which the following occurs: "There is no doubt that the introduction of the rapidly acting barbiturates constituted a major advance in anaesthesia between the wars." I would be the first to admit that the subject of intravenous anaesthesia was not dealt with adequately, but to cover the whole of "Recent Advances" in 3,000 words was a task far beyond my powers.—I am, etc.,

St. Albans, Herts.

C. LANGTON HEWER.

Discovery of Chloroform as an Anaesthetic

SIR,—As a small addition to Dr. J. Y. Simpson's account of the "Discovery of a New Anaesthetic Agent More Efficient than Sulphuric Aether" quoted in the *Journal* of Oct. 12 (p. 541), Dr. Matthews Duncan told me, when I was clerking for him at St. Bartholomew's Hospital in 1886, that the chloroform used was found by him in the chemical laboratory of Prof. Gregory in Edinburgh and that he took it to the meeting on the celebrated occasion when the discovery of chloroform as an anaesthetic was made. He stated that he and several of the dressers in the clinic had made themselves quite ill by inhaling various volatile drugs, but that as he was the person who took the chloroform to the meeting he was entitled to some of the credit of the discovery.—I am, etc.,

Faversham.

PRIDEAUX G. SELBY.

The "Silver Ring"

SIR,—There is a suggestion of panic implied in the communication of the honorary secretary of the Family Planning Association (Oct. 19, p. 599), criticizing the "sudden revival" of the "silver" or "Grafenberg" ring as a means of contraception. Less bias and closer scientific scrutiny is advised before wholesale condemnation of the method can be justified.

The question of the choice of a contraceptive method should be decided on: (a) the personalities involved, (b) their previous experience, if any, of contraceptive measures, (c) the degree of security desired, and (d) the indications for or against any particular method of contraception. Only a very small proportion of the population seek contraceptive advice and it can therefore be accepted that the majority of married couples are content to carry out their own ideas on the subject. When men or women seek scientific information, however, they should be advised on the foregoing basis.

It is clear that in the case of erotic, unstable, and unintelligent types any method necessitating preparation of one kind or another would not be without danger. It might also be bad advice to suggest the use of an occlusive cap to an aesthetic individual who may find the manipulation "more trouble than its worth." Some women are so constructed that a cap is not well retained. Others find a sheath irritating, locally and psychologically, and numerous men report interference with pleasure and/or potency with the rubber condom.

The "safe period" and "withdrawal" methods are used by many couples who for financial reasons or inability to find suitable accommodation are temporarily reluctant to start a family but who, nevertheless, are glad enough to welcome the baby in the event of an "accident." It is a very different story when the wife has advanced cardiac or renal insufficiency, pulmonary tuberculosis, gross neurosis, or incipient psychosis. It is then necessary to recommend a more certain contraceptive method rather than expect such patients to submit to therapeutic abortion.

Failure with an occlusive cap would naturally tend to bring that particular method into disrepute as would discomfort and discharge in the case of the "Grafenberg" ring. It is obvious that a foreign body in the uterus would be contraindicated in a case of gonococcal cervicitis or other infection. No hard-and-fast rules can be laid down except that contraceptive advice should only be given by those who have practical experience of the various methods and technique and who, in addition, have some knowledge of sexual psychology.

It is quite inaccurate to suggest that no progress has recently been made in contraceptive technique. Experience with the "Grafenberg" ring has proved it a most satisfactory method of contraception provided that it is properly applied with all necessary safeguards in suitable patients. I have found less than 5% in something approaching a thousand cases exhibit a mild menorrhagia. I have not encountered any cases of failure or infection which could be attributed to the ring per se. Further, pathological examinations in several hundred diagnostic curettages, which I have had carried out as a routine in all cases when the ring is changed after twelve months, have failed to indicate any gross uterine changes. I propose publishing these results at a later date. I, myself, always regard the insertion of a Grafenberg ring as something in the nature of a minor operation, which should only be performed in a nursing home and under an anaesthetic.

I entirely agree that a simpler and more generally applicable method of contraception is desirable and that further research in this direction should be stimulated, especially as the most consistent factor in precipitating neurosis in women over 35 years of age is fear of pregnancy. I cannot help but feel that the criticism which has been directed against the "Grafenberg" ring has been determined by a survey of cases in which the technique of insertion was faulty or, alternatively, in which a "Grafenberg" ring would appear to have been contraindicated.—I am, etc.,

London, W.I.

EUSTACE CHESSEY.

Treatment of Ingrowing Toe-nail

SIR,—I am very glad to see from Dr. J. C. Leedham-Green's letter (Oct. 19, p. 589) that he has found my method of treating ingrowing toe-nail so successful. There is, however, one point which he has not mentioned which I think is perhaps the most important of all and that is the treatment of the spur on the nail which is found on the affected side. This is so obviously the cause of the irritation and pain that the temptation is always to remove it. If this is done recurrence is almost certain. The correct procedure is to lift that edge of the nail with the spur upwards and over the surrounding tissue, packing

underneath, thus preserving the full width of the nail, and every day to raise it a little more. If this is done and the nail subsequently cut square across there will be no recurrence. The spur is undoubtedly caused by cutting the nail in a rounded fashion and leaving a small portion at the end.—I am, etc.,

Taynult, Argyll.

P. F. CHAPMAN.

Novel Method of Digital Traction

SIR,—Our attention has been drawn to Dr. Kenneth MacLeod's recent description of a novel method of digital traction by means of a thread passed through a hole in the nail and attached to a "banjo" splint (Oct. 26, p. 614). We have used this method at Rinkwood Hospital, Worcester, for more than two years, and have incorporated additional refinements such as the use of elastic in the extension and the fitting of a second "banjo" loop at right angles to the first to give support by means of little rubber slings under the proximal inter-phalangeal joints for those cases in which this is desirable. The appliance has proved most useful for minor fractures, peripheral nerve injuries, etc. We are sorry to disappoint Dr. MacLeod, but his "new" method is an old-established practice at our hospital.—We arc, etc.,

Worcester.

E. W. BINTCLIFFE.
HIREN DE.

SIR,—This method can hardly be called novel. On page 317 of Trueta's *War Surgery*, published in 1943, a better procedure is illustrated, thanks to the simple device of threading the end of the nail and the retention of all the finger joints in flexion rather than in extension, the latter being the undesirable position maintained by the "banjo" splint shown in the photograph accompanying Dr. MacLeod's memorandum.—I am, etc.,

Swindon.

F. LOUIS.

Obituary

SIR EDWARD THORNTON, K.B.E., M.R.C.S.

We regret to learn that Sir Edward Thornton, formerly Secretary for Public Health and Chief Health Officer for the Union of South Africa and D.G.M.S. of the Union Defence Forces with the rank of brigadier, died on Oct. 26 at Pretoria. He had been chairman of the Pretoria Division of the B.M.A. and president of the Northern Transvaal Branch, and presided over the South African Medical Congress in 1934.

Edward Newbury Thornton, sixth son of Thomas Thornton, of Sporre, Swaffham, Norfolk, was born on June 10, 1878, and from Cheltenham College came to study medicine at the London Hospital, qualifying M.R.C.S., L.R.C.P. in 1902 and later taking the Cambridge D.P.H. After service in the South African war and on plague duty in India he entered the Public Health Department of Cape Colony as additional medical officer in 1903, and in 1910-14 was medical adviser to the Cape Province Administration and chief local government inspector of the Province. At the outbreak of the 1914-18 war he joined the South African Expeditionary Force and in 1915-20 commanded the large South African Military Hospital at Richmond Park, Surrey, where he inaugurated the scheme for the vocational training of disabled soldiers during their stay in hospital, and was chairman of the executive committee on vocational training in military hospitals in the London District. He was created K.B.E. (Military Division) in 1919. On returning to South Africa he was appointed D.M.S. of the Union Defence Forces and assistant health officer to the Union, and chairman of the Housing Board. His early work as a plague officer in the Punjab at the beginning of the century led the Government of Nigeria in 1926 and the Administration of the Uganda Protectorate in 1930 to seek his advice on the control of that disease.

Sir Edward Thornton was a versatile man of great energy. He published many reports and scientific articles, and at one time held the chair of public health in the Witwatersrand University; he had a seat for a long period on the South African Medical Council and was an authority on the organization of State-aided hospitals and charitable institutions.

C. E. K. HERAPATH, M.C., M.D.

We regret to announce that Dr. Charles Edward Kynaston Herapath, a former chairman of the Bristol Division of the B.M.A., died on Nov. 4 aged 64. His father was the late C. K. C. Herapath, and he studied at the Bristol Medical School, taking the English Conjoint qualifications in 1907, the M.B., B.S. Lond. degrees in 1908, and the M.D. two years later. His earliest appointments were those of house-physician and house-surgeon at the Bristol Royal Infirmary, and he was for some years physician to the Bristol Dispensary. During the war of 1914-18 he held a temporary commission as major in the R.A.M.C. and won the Military Cross; four years after his return to civilian life he was awarded the Colston research fellowship.

For many years Dr. Herapath was honorary physician and Dean of Faculty at the Bristol Royal Hospital, clinical lecturer in medicine in the University of Bristol, and cardiac specialist to the Somerset County Council; he was also honorary physician to the Winford Orthopaedic and Heart Hospital, and consultant to the Clevedon Cottage Hospital, the Northwood Mental Hospital, and Southmead Hospital. He was a member of the Association of Physicians of Great Britain and Ireland and of the Cardiac Society, and published a number of papers on diseases of the heart, which appeared in these columns and in the *Lancet*. He joined the British Medical Association in 1909, was joint honorary secretary of the Bath and Bristol Branch for ten years, and chairman of the Bristol Division in 1936. At headquarters he served for four years on the Medical Students and Newly Qualified Practitioners Subcommittee.

We regret to announce the death of Prof. MARCEL BRULÉ of Paris. In later life a well-known physician, he was formerly Chef de Laboratoire of the Faculté de Médecine of Paris, where his work on liver diseases and especially on jaundice made his name familiar far beyond the borders of France. He was an old friend of Sir Humphry Rolleston and of many other physicians in Britain and America.

Grief came to the medical profession of Cheltenham and to his numerous patients when Dr. BASIL TAYLOR died on Oct. 24 at the age of 62 after three weeks' illness. A son of the late Rev. George Taylor, rector of Great Witcombe, he studied at Durham University and graduated M.B., B.S. in 1908. He then entered the Royal Navy, from which he retired in 1919 with the rank of surg. lieutenant-commander. He saw service in the original *Dreadnought* and with Evans of the *Broke*. J. R. C. writes: Basil Taylor came to practice in Cheltenham 24 years ago and was appointed on the medical staff of Cheltenham College and also to the Cheltenham Hospital for Sick Children. Endowed with an extraordinary charm of personality, a lasting boyish temperament, always courteous, always cheerful, he made one think that he brought with him from his life in the Navy some of the freshness and vigour of the sea. I think that it was his work at Cheltenham College that was nearest his heart, and his temperament made him a welcome and successful doctor with that observant and critical patient the public school boy. He won their confidence, and they knew that no matter how hard-worked he might be they came first. The funeral service was held at the College chapel and was attended by the Headmaster, the staff of the College, many of the medical profession, and a large congregation of his patients and friends. Devoted to his patients, loyal to his colleagues, happy in his home, it may be said that he was fortunate in his life and also fortunate in his death that he should be mourned by so many. He had been a member of the B.M.A. for 34 years. He is survived by his widow and two sons, both majors in the Royal Artillery. A third son, also a major in the R.A., died this year.

Dr. C. B. VAKIL, who died on Oct. 23, was an Indian who spent his professional life in England after qualifying M.R.C.S., L.R.C.P. in 1913 from St. Bartholomew's Hospital. He was born at the end of 1882 and began his medical studies in Bombay. He practised in various parts of London and joined the B.M.A. in 1930. A colleague writes: Dr. Vakil was a man of quiet manner with a deep passion for his ideals—the welfare of his fellow men, the freedom of his country, and the well-being of his patients. These qualities endeared him to all kinds of people; his passing was mourned by a large gathering, including lawyers, doctors, students, business men, journalists, and labourers. He leaves a widow but no children.

The Services

The *London Gazette* has announced the award of the George Cross to Lieut.-Cmdr. PATRICK ALBERT O'LEARY, D.S.O., R.N., a Belgian doctor known to his countrymen as Dr. Albert Edward-Marie Guérissse, who became a British naval officer. The citation reads as follows:

Lieut.-Cmdr. O'Leary was captured by the French police during operations off the south coast of France in April, 1941. He escaped while en route to a French prison, and thereupon set up an organization to help the escape of Allied prisoners of war and evaders. Through his skill and his sustained personal bravery, the organization succeeded, between April and August, 1941, in getting away some 150 officers and men, many belonging to the Royal Air Force. At increased risk to himself, Lieut.-Cmdr. O'Leary was soon forced to expand his organization, to help an ever-increasing number of evaders. To keep the members working at full pressure, and to inspire their confidence, he travelled frequently between the Dutch border and the south of France through numerous German controls, himself escorting numbers of escapees. If any question arose of hazard greater than usual, Lieut.-Cmdr. O'Leary carried out the work himself. In March, 1943, he was betrayed to the Gestapo by a member of his group. Arrested, he was put to many forms of torture in an attempt to make him reveal the names, whereabouts and duties of the other members. He was put in a refrigerator for four hours, he was beaten continually, but never did he disclose information which could be of profit to the enemy. After more ferocious experiments the Germans gave him up as hopeless, and sent him to a concentration camp where he was once again the victim of torture. He was a prisoner in Mauthausen, Natzweiler, Neubremm and finally Dachau. He nearly lost his life in the Neubremm quarries, where he was beaten senseless. Throughout his time in prison, Lieut.-Cmdr. O'Leary's courage never faltered. Numbers of prisoners have given evidence that his moral and physical influence and support saved their lives. On his liberation from Dachau, Lieut.-Cmdr. O'Leary refused to leave the camp, where he had been made "President" of all the prisoners (including some thousands of Russians), until he had ensured that all possible steps had been taken to ease the lot of his fellows. He was then given the opportunity to return to his family, but he insisted on proceeding to France, to trace the surviving members of his organization, and to help them in any way he could. From the time of inception until the end of the war, Lieut.-Cmdr. O'Leary's group was responsible for the rescue and successful return of over 600 British and American officers and men. It is now known that over 250 owe their safety directly to Lieut.-Cmdr. O'Leary, whose fortitude and determination matched every task and risk.

Fl.-Lieut. A. N. H. Peach, R.A.F.V.R., has been mentioned in dispatches in recognition of gallant and distinguished services in Malaya, Hong Kong, and the Netherlands East Indies during the operations against the Japanese ending in March, 1942.

The following appointments and mention in dispatches have been announced in recognition of gallant and distinguished services while engaged in special operations in South East Asia:

M.B.E. (Military Division).—Majors (Temp.) J. G. Dumoulin and A. Rapoport, and Capt. E. J. Harrison. R.A.M.C.

Mentioned in Dispatches.—Major (Temp.) C. E. Aston, R.A.M.C.

CASUALTIES IN THE SERVICES

Fl.-Lieut. RAYMOND GEORGE BLACKLEDGE, previously reported as missing, has now been presumed to have died about Jan. 20, 1945, while a prisoner of war in Japanese hands. He was born in August, 1912, studied medicine at Oxford University and St. Thomas's Hospital and qualified B.M., B.Ch., and M.R.C.S., L.R.C.P., in 1937. After holding house appointments at St. Thomas's, the Radcliffe Infirmary, Oxford, and the Miller General Hospital he was commissioned in the Medical Branch R.A.F.V.R. on Sept. 10, 1940.

Universities and Colleges

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a reception at the College on Oct. 30, to celebrate the centenary of the first administration of ether in this country, the Princess Royal, Hon.F.R.C.S., unveiled a memorial tablet marking the centenary and honouring the four British pioneers, Henry Hill Hickman, James Young Simpson, John Snow, and Joseph Thomas Clover. Dr. A. D. Marston, president of the Association of Anaesthetists of Great Britain and Ireland, in his address pointed out that of the three English pioneers one was a Fellow and the other two were Members of the Royal College of Surgeons of England, and said that no more suitable place for the keeping of their memory could be thought of than within the precincts of the ancient and famous College which was their alma mater. Dr. Marston gave a brief account of the life and work of each of the pioneers and of their contribution to anaesthesia. Hickman's life was short (1800-30). He lived before the actual introduction of anaesthesia, but made experiments on animals and reported them to the Medical Society of London, and was convinced that means would be found to relieve human suffering. Sir James Young Simpson, the celebrated Scottish physician, had attained the age of 35 years and considerable academic distinction at the time of the

first administration of ether in this country. As professor of medicine at Edinburgh University and a leading exponent of obstetric practice Simpson had constantly sought means of alleviating the pangs of childbirth. John Snow, a Yorkshireman, was practising medicine in London when he read in the *Lancet* Bigelow's account of the Massachusetts demonstration, and he began to study the possibilities of anaesthesia at the age of 33. Clover, a native of Norfolk, became F.R.C.S. at the age of 28, and decided to devote his life to the study and practice of anaesthesia. He did much valuable work in restoring ether to its place as the principal routine anaesthetic agent, and spent years in perfecting his famous inhaler.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At the annual meeting of the Royal Faculty of Physicians and Surgeons of Glasgow the following officers were elected for the ensuing year: *President*, Dr. Geoffrey B. Fleming; *Visitor*, Mr. J. Scouler Buchanan; *Honorary Treasurer*, Mr. Walter W. Galbraith; *Honorary Librarian*, Dr. Archibald L. Goodall; *Representative on General Medical Council*, Mr. Andrew Allison.

VICTOR HORSLEY MEMORIAL LECTURE

The Victor Horsley Memorial Fund, which was raised in 1920 to commemorate the services of Sir Victor Horsley to Science and the Empire, is devoted to the giving of a lecture triennially in London entitled the "Victor Horsley Memorial Lecture." By invitation of the Trustees (the Presidents for the time being of the Royal Society, the Royal College of Surgeons of England and the British Medical Association, the senior physician of the National Hospital for the Paralysed and Epileptic, Queen Square, the senior surgeon of University College Hospital, and Mr. Stanley G. Robinson, son-in-law of Sir Victor Horsley) the seventh lecture will be delivered by Dr. F. M. R. Walshe, F.R.C.P., F.R.S., physician to the National Hospital, and physician-in-charge, Neurological Department, University College Hospital, in the Lecture Theatre, National Hospital, Queen Square, W.C., on Wednesday, Nov. 27, at 5 p.m. The title of the lecture is "The Contribution of Clinical Study to the Physiology of the Cerebral Motor Cortex," and the chair will be taken by Sir Alfred Webb-Johnson, Bt., P.R.C.S. Admission to the lecture is free on presentation of visiting card.

Medical Notes in Parliament

HEALTH SERVICE BILL

Royal Assent

Final discussions on the National Health Service Bill arose in the House of Lords on Nov. 6 on a Government motion that the House should consider the reasons advanced by the House of Commons for disagreeing to certain amendments previously made by the House of Lords.

A Lords amendment transferred to the Metropolitan boroughs and the City of London some of the health services which the Bill, as introduced, concentrated under the London County Council. In rejecting this the House of Commons formally expressed the opinion that it was expedient for all services to be provided under Part III of the Bill in any area to be the responsibility of a single authority and that in the County of London, as in other counties, the appropriate authority was the county council.

In defending the decision of the House of Commons the LORD CHANCELLOR said that to be effective the supervision of expectant mothers, and also prenatal and postnatal care, must be co-ordinated with the domiciliary midwives service through one authority responsible for all related facilities. Before the war 25% of the births in London were attended by these L.C.C. services and that figure had substantially increased.

LORD BALFOUR OF BURLEIGH said midwifery was transferred from the borough councils to the London County Council only a few years ago. Integration had remained complete and mothers were unaware that the midwife was the servant of the L.C.C. while the health visitors were servants of the borough councils.

On the motion of the Lord Chancellor the House agreed not to insist on its amendment.

The Major Method of Remuneration

To the amendment made by the House of Lords respecting the remuneration of general practitioners undertaking to provide general medical services under the Act the Commons had disagreed on the ground that it was inexpedient that the method of remunerating the doctors providing these services should be laid down in the Statute.

The LORD CHANCELLOR submitted that the peers' amendment was too restrictive. He said it would be ridiculous if an Act of Parliament were necessary to vary the method of remuneration agreed to by the profession. He moved that the House should not insist on the amendment. He could not say what the proportion of salary should be in the normal case. "That must depend on the consultation which we shall enter into with the profession itself, but the Government's intention, subject to what the profession may say, is clear. It has been said several times. It is that a salary should be an element only, a minor matter, and that the major method of remuneration should be by way of capitation fees. That has been stated by the Minister several times, and was restated when the Commons considered this matter again."

LORD LLEWELLIN, who had originally moved this amendment, rose to say he accepted the Lord Chancellor's motion.

LORD HORDER said the principle which underlay the amendment had not been modified by the Minister, but the position had, to some extent, been clarified. Mr. Bevan's assurance that the main part of the remuneration would be by capitation would, however, not bind future Ministers. If the regulations on this and other matters were to come up for discussion before they were put into operation, then medical men would feel more satisfied. He understood that by regulation it was still possible to change the percentages of the two forms of remuneration, or even to do away with one or other of those forms. If the capitation method of payment were done away with at some future time the fear that the Bill was the thin end of the wedge in respect of a national service would be intensified in the minds of doctors. Colleagues in general practice were left cold by Mr. Bevan's assurance that it was not the intention of the Government to make the present proposal the beginning of establishing a full-time salaried service. If the Minister wished to have the profession with him, as he had said, he could have gone further. It was still doubtful whether the doctors were going to come in willingly and enthusiastically to work the scheme. Lord Horder hoped they would. The pose of the Government of doing certain things for the sake of the doctors so that they could do their work without financial anxiety and could be freed from competition was odd when no clamour in respect of those matters had been heard from the rank and file of the profession. Doctors were not dissatisfied with a certain amount of insecurity when they started nor with a healthy spirit of competition as they went along.

LORD MORAN thanked the Lord Chancellor for his reasonableness during the discussions on the Bill. The Lord Chancellor had not argued that the basic salary was a measure of security for the young practitioner beginning practice. He had not suggested a basic salary to prevent early casualties in the legal profession where these were much heavier. Barristers did not want a basic salary. Neither did the doctors. Lord Moran said he had been dean of a medical school for twenty-five years where each year 60 or 70 men qualified and went into practice. He had never heard security discussed. There was a fundamental belief throughout the profession that there was something profoundly wrong with a man if he could not make a livelihood in medicine. This question of a basic salary was a figment of the political imagination, a debating point and no more. A second argument had been that payment by capitation fee led to abuses and undesirable practices. In the House of Commons the Minister had said that did not apply to more than a very small proportion of doctors. So, said Lord Moran, because there were a few black sheep, the whole remuneration of the rest of the medical profession was to be altered in a way which the profession almost unanimously felt might result in a deterioration of medical practice. When the Bill became law the vast majority of the profession would work under it. It was of enormous importance that they should have confidence in the Ministry of Health. That confidence would not be created if there were impugning by the political world of the honesty of the great body of the profession. Debates on this particular amendment had seemed unreal to the profession because, generally speaking, doctors did not believe that the reasons given for introducing a basic salary were the real ones. They thought it was an instalment, to be increased from time to time, towards a condition of affairs which would ultimately result in the basic salary becoming a whole-time salary. Ministers of Health came and went, but this principle remained a basic faith in the Party which had so often expressed it. If the basic salary ever became a whole-time salary, Parliament would embark on a condition of affairs whose effect on the proficiency of the profession could not be calculated.

The House then agreed with the Lord Chancellor's motion not to insist on its amendment.

Later in the same day a Royal Commission signified the Royal Assent to the National Health Service Bill.

Release of Medical Officers

On Nov. 6 Sir ERNEST GRAHAM-LITTLE asked whether Mr. Bellenger knew that doctors in the Forces over-seas suffered from uncertainty with regard to their release, their anxiety being occasioned by the issue at the end of 1945 of a Government statement reducing the ratio of doctors to two per thousand; which was contradicted by a later Army circular fixing the ratio at 2.75 per thousand. He asked the Minister to inform the officers concerned of the actual position.

Mr. BELLENGER replied that the ratio of two doctors per thousand troops was agreed under the conditions existing at the end of 1945 to enable the maximum number of doctors to be returned to civilian practice for the winter months. By that measure the Army alone was able to release 5,600 doctors by the end of February. Present estimates, based on an over-all cover of 2.75 doctors per thousand British troops, provided also for medical commitments other than those that could be considered a purely military responsibility and for military families overseas. The release programme for medical officers must depend upon the strengths and deployment of the Forces generally. Dates for release of the various age-and-service groups were announced as soon as possible. The release of doctors was thus inevitably linked with the release programme for the Army as a whole. Whatever the percentage of doctors per thousand, there must necessarily be some uncertainty for individuals until a definite programme had been announced. There was no more cause for uncertainty in the minds of doctors than in the minds of any other members of the Forces.

West African Medical Services

Mr. A. CREECH JONES told Mr. SORENSEN on Nov. 6 that the expansions of the medical services in the West African colonies envisaged for the next ten years were considerable. Nigeria was devoting nearly £9,000,000 under its £55,000,000 development plan to these services and by 1956 would have more than doubled its present annual expenditure of nearly £1,000,000. The number of hospital beds would be multiplied two and a half times and the medical staff trebled. In addition, over £8,000,000 was to be spent on improved water supplies, which should have a marked effect on the health of the people. In proportion to its resources, Sierra Leone proposed expenditure of a similar order. Although the plans for the Gold Coast and Gambia were not yet final, they provided for substantial expansion. Mr. Creech Jones added that having regard to the limitation of the available resources and the need of other equally essential services, it would not be wise to contemplate further expansions unless the future revenues of the territories concerned turned out to exceed expectations.

Medical News

Five candidates were nominated at Edinburgh University on Nov. 6 for the Scottish Universities Parliamentary by-election to fill the seat in the House of Commons relinquished by Sir John Boyd Orr. Two are medical men: the Right Hon. Walter Elliot (Conservative), and Mr. R. Scott Stevenson, F.R.C.S.Ed. (Liberal National). Polling at each university will take place between Nov. 22 and 27 on days appointed by the several Vice-Chancellors. The result will be declared on Nov. 29 in Edinburgh.

The London Medical Exhibition will be resumed, after a wartime break, at the New Hall, Royal Horticultural Society, Westminster, London, S.W.1, from 11 a.m. to 6.30 p.m., daily from Nov. 18 to Nov. 22 inclusive. Doctors who wish to attend, and have not been sent an admission card, can obtain one, free of charge, from the Secretary, London Medical Exhibition, 194-200, Bishopsgate, London, E.C.2. Tel. Bis. 2148.

A meeting of the Hunterian Society will be held at Apothecaries' Hall, Blackfriars Lane, Queen Victoria Street, E.C., on Monday, Nov. 18, at 8.30 p.m., when the motion "That the Advertisement of Proprietary Medicines is a Menace to the Public" will be discussed. For the motion: Mr. Hugh N. Linstead, M.P., Dr. G. H. Day; against the motion: Mr. Arthur Mortimer, Mr. J. S. Walmsley. The meeting is open to medical and non-medical guests and the Council hopes that Fellows will avail themselves of the opportunity to invite guests who are interested in the subject.

A lecture on "New Factors concerned in the Coagulation of Blood" will be given at University College Hospital Medical School (Lecture Theatre No. 1) by Dr. P. A. Owren (Akers Hospital, Oslo, Norway), on Friday, Nov. 22, at 4.30 p.m., when the chair will be taken by Prof. C. Rimington. Students and others interested in the subject are invited.

A meeting of the Middlesex County Medical Society will be held at Chase Farm Hospital, Enfield, on Thursday, Nov. 28, at 3 p.m., when clinical cases will be shown and a paper read by Mr. J. A. Dunlop on "Pre-vesicular Prostatectomy: Experiences with 25 cases."

The Albert Medal of the Royal Society of Arts, awarded jointly this year to Sir Alexander Fleming and Sir Howard Florey for their services in the discovery and development of penicillin, was handed to them privately on Nov. 4 by Viscount Bennett, president of the Society. Lord Moran, P.R.C.P., and Sir Alfred Webb-Johnson, P.R.C.S., were present.

Mr. Horace H. Rew, Secretary to the Examining Board in England, will retire on Nov. 30 and will be succeeded by Mr. F. M. Stent, the present assistant secretary.

Two American visitors of interest to the medical world who have recently been in England are Dr. Kendall Emerson, managing director, and Mr. F. D. Hopkins, executive secretary, of the National Tuberculosis Association of the U.S.A. The Duchess of Portland and the Council of the National Association for the Prevention of Tuberculosis entertained Dr. Emerson and Mr. Hopkins to luncheon on Nov. 1, when the keynote of the speeches was the importance of the closest co-operation between Great Britain and the United States in the fight against tuberculosis. At a Council meeting afterwards, attended by Dr. Emerson and Mr. Hopkins, various matters of interest to the two associations were discussed, including the situation which will confront voluntary bodies when the World Health Organization comes into being.

Two distinguished Brazilian medical men are now in this country as the guests of the British Council. Dr. Reynaldo Neves de Figueiredo, who is here to study anaesthetic techniques, is head of a team of eight doctors in the General Hospital, Sao Paulo, who specialize in anaesthesia. Dr. Moacyr Alvaro is one of Brazil's leading ophthalmic surgeons, and will see something of the work of eye hospitals in London.

Dr. John Charles Wootton, part proprietor and medical superintendent of Haydock Lodge, Haydock, Lancs., a nursing home for mental patients, successfully appealed on Nov. 5 against conviction and a £50 fine at Newton-le-Willows because forms claiming priority milk were incorrect. The Liverpool County Quarter Sessions Appeals Committee quashed the conviction with costs.

Surgeon Rear-Admiral Sir Gordon Gordon-Taylor has been honoured by the award of the Legion of Merit, Degree of Commander, by the President of the United States of America.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* there was a general increase in the prevalence of measles 499, scarlet fever 161, whooping-cough 124, paratyphoid 67, and diphtheria 36.

Notifications of scarlet fever showed the largest rises in Yorkshire West Riding 42 and Staffordshire 32. There was an increase in the incidence of diphtheria in Lancashire 15; almost an eighth of the total cases of diphtheria were notified in Liverpool C.B. The increase in cases of whooping-cough was mainly confined to the Midlands; the largest local rise was Warwickshire 35 and the largest fall was Lancashire 36. The most notable increase in the notifications of measles was Durham 166, and 54 further cases appeared in Montgomery, Llanfyllin R.D., where 21 and 24 cases were reported in the preceding two weeks. The only return of any size for cases of dysentery was London 18 (Lewisham 9). Notifications of paratyphoid continue to reflect the outbreak in Sheffield C.B.

In *Scotland* an increased incidence was recorded for scarlet fever 54, acute primary pneumonia 37, and diphtheria 9. A decline was reported for measles 38 and dysentery 16. The largest increases in cases of scarlet fever were Glasgow 17, Dundee 11, and Aberdeen 9. A rise of 15 in the notifications of diphtheria occurred in Glasgow.

In *Eire* the chief variations in the trends of infectious diseases were increases in scarlet fever 19 and whooping-cough 13 and a fall in diarrhoea and enteritis 11.

In *Northern Ireland* the returns showed little variation from those of the preceding week. A further decline was recorded in the outbreak of typhoid in Armagh U.D., where 6 cases were notified as compared with 15 and 25 in the preceding two weeks.

Week Ending November 2

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,187, whooping-cough 1,549, diphtheria 274, measles 3,374, acute pneumonia 485, cerebrospinal fever 40, dysentery 69, acute poliomyelitis 25, paratyphoid 66, typhoid 6.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct. 26.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Owing to a fire at the printers in Dublin it is not possible to publish the return of births and deaths in Eire for the week ended October 26.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Westcent, London*.

ANY QUESTIONS?

Treatment of Polycythaemia

Q.—What is the most recent treatment for polycythemia? Is there any permanent cure?

A.—To reply to the second half of this question first: there is no permanent cure for polycythaemia.

The condition is accompanied by an increase in the viscosity of the blood as well as by a raised blood volume. It is uncertain to which of these the symptoms are to be attributed, but the aim of treatment is to reduce both. Venesection is probably the most commonly used method. Phenylhydrazine serves the same purpose by destruction of red blood cells, but it requires careful administration or a severe haemolytic anaemia may result. Radiotherapy is a third method which aims at inhibiting erythropoiesis. The most satisfactory results have been obtained by irradiating the whole body at a distance of 2 to 2.5 metres from the tube; 30 to 50 r are given daily, and treatment is stopped when the leucocytes fall to 4,000 per c.mm. After a latent period of one to two months the red cell count starts to fall, and a prolonged remission, sometimes of two years, is obtained. (Pierson and Smith, *Amer. J. Roentgen.*, 1940, 43, 577.)

More recently radioactive phosphorus has been employed. This isotope, P^{32} , is concentrated in the bone marrow, where it emits beta-rays and thus inhibits haemopoiesis; it has a half-life of 14.3 days. The average dose is 5 to 10 millicuries, given intravenously as an isotonic solution of sodium dihydrogen isotopic phosphate. Remissions of over two years have been produced. (Erf and Lawrence, *Ann. intern. Med.*, 1941, 15, 276; *Blood*, 1946, 1, 202.)

High Flying for Whooping-cough

Q.—Is the treatment of whooping-cough by high-altitude flight of any value?

A.—A high-altitude flight can have no effect on whooping-cough from the point of view of its treatment as a specific infection. The occurrence of focal areas of lung collapse, which is a serious complication of the disease, might be mitigated by the effect of altitude. The return of the child to normal heights would, however, permit their recurrence, so that any relief would probably be temporary. See also an annotation on this subject in the *Journal* of Dec. 26, 1942 (p. 758).

Plantar Warts and Fungous Infection

Q.—Could you tell me the preventive treatment for (1) plantar warts, and (2) fungous infections contracted in swimming-pools and baths?

A.—Plantar warts are caused by a virus from a patient with warts entering the epidermis of the sole, probably through a small abrasion. Epidemics in communities such as schools can be prevented by the following measures: (1) Removal of carriers. All feet should be examined at weekly intervals; any child with a plantar wart should be banned from barefoot exercise, bathing, etc., until cured. He should be provided with a special bath-mat. The incubation period of warts may be many months, so that the inspection must be continued for six months after an epidemic has apparently ceased. (2) Children with warts on other parts of the body should also be treated.

(3) In the event of an epidemic, barefoot exercise should be stopped and slippers should be worn in changing-rooms. (4) The insides of all shoes should be examined for nails, etc., which might damage the skin of the sole. The arrest of an epidemic of warts by the removal of a carrier is described by McLaughlin and Edington (*Lancet*, 1937, 2, 685).

The only satisfactory way of avoiding the risk of fungous infections at swimming-pools is to wear bathing-shoes. It is improbable that paddling the feet for a few minutes in hypochlorite or other antiseptic solution does more than satisfy the local health authorities. Rubbing in Whitfield's ointment before bathing is more effective but rather messy and carries some risk of dermatitis. In the event of an epidemic, careful search should be made for carriers. These should be intensively treated and provided with their own bath-mats and forbidden to walk about barefoot. The transmission of infection was the subject of a questionnaire to American dermatologists (*J. invest. Derm.*, 1940, 3, 523). Opinions varied from those who said precautions were unnecessary to those who even swabbed the bath out with carbolic acid.

Haemospermia

Q.—In young men what are the causes of haemospermia other than malignant disease, chronic granulomata, and venereal disease?

A.—Haemospermia in young men is not at all uncommon and may be compared with epistaxis. It is probably due to congestion of the parts and possibly rupture of a small blood vessel; it seems probable that the bleeding may also occur in the neighbourhood of the verumontanum during a period of sexual stimulation. Another cause to be borne in mind is prostatic-vesiculitis, especially when due to tuberculous infection. Few textbooks on surgery even mention the condition: see Romanis and Mitchiner, *Science and Practice of Surgery*, J. and A. Churchill, Ltd., 1941, 2, 960.

Wilson's Disease and Rh Incompatibility

Q.—Kernicterus and certain types of infantile cirrhosis have been shown to be late results of Rh incompatibility between mother and child. Has Wilson's disease any connexion with the development of maternal Rh antibodies?

A.—The answer to this question is not yet known with certainty. No large series of cases of Wilson's disease has been published with details of the blood groups. Juvenile hepatic cirrhosis and kernicterus may both result from iso-immunization of the mother due to Rh incompatibility, but, while it is an attractive speculation which has occurred to many workers on Rh problems that Wilson's disease (hepato-lenticular degeneration) might have a similar aetiology, there is no proof in favour of this hypothesis and the available evidence is against it. Wiener and Brody (*Science*, 1946, 103, 570) have reported three cases of Wilson's disease in which they failed to detect evidence of iso-immunization of pregnancy, and they give it as their opinion that this is not the origin of Wilson's disease.

Carey Coombs Murmur

Q.—Is the Carey Coombs murmur in acute rheumatism due to accentuation of the normal third heart sound? Is it definitely indicative of a subsequent mitral stenosis or organic mitral disease? How long after this murmur does the diastolic murmur of mitral stenosis arise? Does myocardial failure often develop in rheumatic hearts which show no evidence of valvular disease?

A.—The Carey Coombs murmur is a soft, short mitral diastolic murmur which appears during the course of active rheumatic carditis and which cannot be attributed to mitral stenosis. Carey Coombs thought it was due to stiffening of the mitral cusps, and commented on its development in the later stages of active carditis and on its persistence. Bland, White, and Jones (*Amer. Heart J.*, 1935, 10, 995), however, reported on its not infrequent disappearance as the patient recovered from the acute attack, and presented necropsy evidence indicating that it was very doubtful if the murmur could have been attributed to mitral valvulitis—the macro-

THE MENOPAUSAL SYNDROME

MENOPAX

ANTI-PRURITIC CREAM

In this preparation the causal effect of stilboestrol is combined with potent analgesics producing *prompt and prolonged local anaesthesia*, thus achieving a double purpose; it stops the irritation, soothes and heals the excoriated surfaces, and provides for a more normal nutrition of the tissues by augmenting the deficient local supply of oestrogen.

Menopax Antipruritic Cream is of proven clinical value in pruritus and kraurosis vulvae, senile pruritus, vaginal ulceration, early cases of leucoplakia vulvae, etc. Pruritus ani and haemorrhoids in both sexes are equally benefited to a remarkable extent.

Amethocaine	0.5%
Benzocaine	5.0%
Diethyl-Stilboestrol ...	0.1%
Camphor	2.0%
Zinc Oxide	5.0%
Terpineol	1.0%

Clinical samples and literature will be gladly sent on request.

CLINICAL PRODUCTS LTD., RICHMOND,
SURREY.

A SULPHONAMIDE

Active in pus

Experiments with 'Marprontil' (4-aminomethylbenzene hydrochloride) have shown it to be highly effective against anaerobic organisms; and active in the presence of pus.

Clinical trials in progress in this country indicate that it is often effective against strains of bacteria that have become sulphonamide-resistant.

It is intended for local application to infected wounds as dusting powder, cream or solution.

'MARPRONTIL'

TRADE MARK—BRAND OF SULPHABENZAMINE HYDROCHLORIDE

Powder in bottles of 10 g.; 'Marprontil' Compound (10% with 'Prontosil' Album) in bottles of 15 g. and 100 g. Literature upon request.

The diagram above clearly shows how this spring mattress provides correct and natural support

The comfort of the patient is greatly increased, full relaxation encouraged and matrons say that better sleep results from the use of "Intalok" spring mattresses.

The yielding support is the reason.

INTALOK

The springs do not rust but gain by stoving

INTALOK LTD., Redfern Road, Tyseley, Birmingham 11

Persistent Post-traumatic SKIN ULCERATION

A cross leg flap graft and immobilization with Gypsona

CASE HISTORY

The patient, aged 34, broke his leg while jumping between ships. A fracture involved the lower end of the left tibia and fibula. He was in plaster for about eight months and in Elastoplast for a further month or so. During these ten months

Fig. 1.

he had numerous sequestra from the fracture site, and when everything else had healed the ulcer remained at the inner side of the junction of the middle and lower thirds of the leg. On the 30th October he was admitted to hospital. The skin around the ulcer for at least 2 in. was found to be of poor quality. Radical excision of ulcer and surrounding area of unstable skin was performed.

A cross-leg flap from opposite calf was sutured into the defect. The raw donor area was covered with thin razor graft, dressed with tulle gras

(Jelonet). Previously applied 'Gypsona' plaster boots were then joined with additional 'Gypsona' bandages.

After three weeks the plaster was removed and three days later the flap was divided. In two months the flap was completely healed and the patient discharged.

The details and illustrations above are of an actual case. T. J. Smith & Nephew Ltd., manufacturers of Elastoplast,

are privileged to publish this instance, typical of many in which their products have been used with success, in the belief that such authentic records will be of general interest.

*Two advances
in Opiate Medication*

DILAUDID

TRADE MARK dihydromorphinone BRAND

Improved Morphine Preparation

Whilst the analgesic power of "Dilaudid" is five times as great as morphine its hypnotic effect is considerably weaker. The euphoric element is largely subdued and addiction risk correspondingly lowered. Tolerance is improved, an increase of dosage rarely necessary. The effect on peristalsis is slight and much less persistent than with morphine.

DICODID

TRADE MARK dihydrocodeinone BRAND

Powerful Antitussive

Occupying a place midway between morphine and codeine, "Dicodid" exerts a selective influence on the cough centre. Better tolerated than morphine, it also interferes very much less with expectoration. Causes no constipation.

for the sake of convenience, we have decided to change the name of our increasingly popular gauze dressing from "Optrex Tulle" to "Optulle". The dressing itself, however, has not been altered in any way. It remains exactly the same—a wide mesh gauze impregnated with Balsam of Peru in a greasy base—suitable for a wide variety of uses, particularly for raw surfaces, including burns and septic wounds, and for plastic surgery cases.

*Supplied in tins of 24 dressings, 4 ins. square (approx.)

pic lesions were sometimes trivial. They thought that it might depend upon left ventricular dilatation.

This murmur is not an accentuated third heart sound, though Carey Coombs stresses its frequent association with an accentuation. Nor is it theoretically "definitely indicative" of subsequent mitral stenosis or organic mitral disease; but in practice it usually is so, not only because Carey Coombs's explanation may still be correct in many cases, but also because its occurrence denotes an attack of rheumatic carditis of some severity from which the mitral valve is unlikely to escape.

The diastolic murmur of mitral stenosis is said to take two to five years to develop after the attack which first caused mitral valvulitis. Mitral stenosis rarely arises without a preceding mitral systolic murmur, but may do so. Heart failure very rarely, if ever, develops in a case of rheumatic heart disease owing to no evidence of a valvular lesion.

Preparing for Lactation

Q.—Is the use of stilboestrol ointment advisable in preparing nipples for lactation?

A.—It is very difficult to say whether any particular ointment or other remedy is of real value in the preparation of nipples for lactation. Claims are made for many substances, but these are rarely based on controlled observations. Stilboestrol ointment has been tried out in some centres, but has been more often used for the treatment of cracked nipples during the puerperium than the preparation of the nipples during pregnancy. Since one of its actions is to promote the growth of epithelium its use for the former purpose appears more rational.

There would be no harm in the inquirer carrying out a clinical trial, but it should be borne in mind that, even though the results appear to be good, it will have to be shown that the effect is due to the ointment itself, or rather its stilboestrol content, and not to the massage incidental to its application. Nowadays there is a widespread scepticism as to the value of any of the special preparations advised for the nipples during pregnancy, and the tendency is to advise no treatment other than the regular washing away of dried crusts of secretion from the mouths of the ducts, and gentle manipulation to ensure that the nipple stands well out from the surrounding skin.

Vitamin E in Angina Pectoris

Q.—In an American weekly it is reported that a Canadian doctor has had great success in the treatment of angina with large doses of vitamin E. Is this report accurate?

A.—Vogelsang and E. V. Shute (*Nature*, 1946, 1, 772), studying the effect of high-dosage vitamin E (α -tocopherol acetate) in purpura,¹ noted the good influence of this factor upon coronary heart disease. "A study of a series of cardiac patients, carried out with the help of Mr. Floyd Skelton and Mr. Wilfrid Shute, suggests (a) vitamin E in large dosage (200 to 400 mg. 'Ephynal' Hoffman-LaRoche) has no apparent effect on normal hearts, even after administration for many months at a time; (b) its effect upon patients having congestive heart disease and the anginal syndrome is marked; it increases exercise tolerance and diminishes or abolishes anginal pain during the period of its administration; its diuretic effect² is pronounced. The effect of vitamin E upon coronary pain may be produced by a direct action on the coronary vessels or by influencing the metabolism of the heart muscle. The first possibility is suggested by an older observation³ on the effect of vitamin E in dilating the local capillaries in senile vulvitis. Work on the purpuras raises another possibility, too. Small haemorrhages into the walls of the coronaries⁴ or into the heart muscle itself may produce such pain. It is now clear that such extravasations may be either prevented or reabsorbed by means of vitamin E. When vitamin E was given in large doses over long periods of time some patients complained of cardiac irregularities. These were relieved by reducing the medication to low levels."

The successful treatment of angina pectoris with large doses of vitamin E awaits further confirmation. There is not much more available evidence on the point, but Bruger (*Proc. Soc.*

exp. Biol., N.Y., 1945, 59, 56) seemed to show that this vitamin increased the deposition of cholesterol in the aorta of cholesterol-fed rabbits. Until there is much more evidence indicating benefit from the use of vitamin E in angina pectoris, such treatment is not advised.

Pseudo-reaction in Schick Testing

Q.—The usual explanation of a pseudo-reaction in the Schick test is given as "sensitivity to bacterial protein." How does this bacterial protein get into the toxin filtrate? Is the protein not more likely to come from the growth medium?

A.—The pseudo-reaction in the Schick test is an allergic reaction, the incidence of which increases with increasing age of the tested community. It is almost certainly a reaction to the diphtheria toxin rather than to the breakdown products of the whole organism, although of course there will be small amounts of bacterial protein in the toxin filtrate. Comparative tests have shown that the pseudo-reaction which is elicited by the injection of Schick toxin corresponds to the Moloney test, which follows the intradermal injection of diluted toxoid, usually 0.2 ml. of a 1/200 dilution. In such a dilution the toxoid is the only foreign protein likely to be present in any appreciable amount, and will therefore be responsible for any reaction elicited. This allergic phase seems to occur when the individual is in the transition stage between susceptibility and immunity to diphtheria, and those giving the reaction probably do not need to be artificially immunized. The suggestion that the allergic reaction is due to proteins in the culture medium is negated by the virtual absence of allergic reactions among troops immunized with tetanus toxoid. The few cases of allergic reaction that have been reported following injections of tetanus toxoid were apparently associated with the protein of a particular peptone that was used early in the production of the toxoid.

Chemoprophylaxis of Respiratory Infections

Q.—I have read recently that in the U.S. Army sulphathiazole was given as a prophylactic against the secondary infections associated with respiratory diseases and that a reduction in incidence resulted. Is this correct?

A.—During the war large-scale trials in the control of respiratory infections by the use of small doses of sulphadiazine (not sulphathiazole) were undertaken in American training units. Very often the main contributor to respiratory infections in these Army camps was streptococcal pharyngitis, and sulphadiazine in doses of 1 g. daily seemed to cut short outbreaks of streptococcal infection, while the incidence of other less well defined respiratory infections was in some instances also reduced. However, an unfortunate sequel was that certain epidemic strains of haemolytic streptococcus became sulphonamide-resistant, and in subsequent years outbreaks of infection due to these drug-fast strains caused a lot of trouble. In this country the use of small doses of sulphonamide to prevent secondary infections after measles or influenza has been advocated, but again there is the risk of inducing drug resistance in the secondary bacterial invader, which is usually the haemolytic streptococcus. It is perhaps wiser to withhold sulphonamides until there is some indication of a secondary bacterial infection—for example, otitis media—and then to treat the infection at this early stage with therapeutic doses of the drug. The risk of reactions from small prophylactic doses is slight, and rheumatic patients have taken doses of 1 to 2 g. of sulphanilamide for many months on end without toxic effects. Sulphathiazole is more likely than sulphanilamide or sulphadiazine to produce toxic or allergic reactions.

For discussion on the chemoprophylaxis of bacterial infections see the *M.R.C. War Memorandum No. 10*, 2nd edit., London, 1945, and refer also to a leading article in the *Journal* of Jan. 13, 1945 (p. 50).

INCOME TAX

Board and Lodging of Locumtenent

N. F. asks "What amount per week can be claimed as a professional expense in respect of board and lodging of locum, living at my house?"

* The only sound basis is a proportion of the total expense of running the private, as distinct from the professional, portion of the house, together of course with the cost of food, etc. Such expenses vary so much between practices that it is impossible to offer any guidance as to an actual weekly amount.

Service in India

Z. X. was on service in India from 1943 to 1946. In 1944-5 he was married and had one child. He has an income of £227 arising from securities in this country.

* If Z. X. can claim to have been a "resident" in this country although personally absent (e.g., if he maintained his wife in a residence here) he can claim the full allowances against the income from securities, as the Indian pay is outside the scope of the United Kingdom tax. If he cannot claim as a "resident," he is entitled to claim in respect of a proportion only of the normal allowances, the proportion being determined by the ratio of the income from securities to the Indian earnings. In reply to a further question we are not aware of any book now available on income tax for medical practitioners and we advise Z. X. to consult his local inspector of taxes, preferably by appointment.

Amount Payable

N. M. E. quotes amounts of income and asks what tax will be payable for 1943-4, 1944-5, and 1945-6.

* Assuming that the whole amount of the life insurance payments are allowable the tax apparently due on the basis of the particulars given are: 1943-4, £103; 1944-5, £115; and 1945-6, £130.

Assistant's Car Transactions

A. C. is an assistant in a country practice. When he joined the R.A.M.C. in 1940 he sold his car for £7; he has just bought another car for £405. His principal proposes to make him a car allowance of £50 a year.

* For the year 1946-7 A. C. should claim an "initial allowance" of 20% of £405=£81, and "depreciation allowance" for the half year to April, 1947, of 25% of £405, i.e., 1/2 of £101=£51, £132 in all. He must of course set against this any sums he receives by way of car allowances, but can deduct the running costs, including licence, insurance, etc. Some adjustments may be required if the car is used for private purposes as well as for work as assistant. No advice can be given with regard to the amount of the car allowance paid by the principal; that is a matter for settlement between the two parties, taking into account the ordinary remuneration.

P. Q. has been acting as an assistant in general practice for three years and has received a car allowance from her employer of £50 a year. She bought a car in 1939 for £130 and sold it on July 9, 1946, for £320, buying another car for £x. She has had little or no wear-and-tear allowance on the old car. What claim can she make for 1946-7?

* She is entitled to base the gross claim on (a) "initial allowance," 20% of £x, (b) "wear-and-tear allowance"—i.e., 25% of £x per annum—i.e., three-quarters of 25% of £x for 1946-7, and (c) running costs, including licence, insurance, repairs, petrol, etc. From the total of these amounts must be deducted a "balancing charge" in respect of the old car, £320-£130=£190 and the £50 car allowance. The difference will be claimable as an expense of carrying out the duties of the assistantship, subject, perhaps, to some further reduction for the private use of the car if it is so used.

Car Transaction—Cost of Maid

K. M. (a) started work as an assistant (with no car allowance) on Oct. 10, 1946, having bought a car in September, 1946; (b) he has to live at the surgery and to employ a maid for dealing with callers and the telephone; otherwise the maid would not be necessary. What can he claim?

* (a) An "initial allowance" of 20% of £300=£60, and a wear-and-tear allowance of 25% of £300 per annum—i.e., say, half of £75—i.e., £37. Total, £60 plus £37=£97. In addition he can, of course, claim the running expenses, licence, etc. If the car is used for private purposes some restriction of the total costs and allowances will probably be claimed by the Revenue. (b) A claim for a proportionate part of the cost of the maid will be allowed, on the basis of an estimate of the time spent on the "professional" part of her work to the total.

LETTERS, NOTES, ETC.

Artificial Limbs for Women

Mr. C. R. HOWARD writes: Regarding the points in the design of the modern artificial limb raised by your correspondent, "L.S.S.W." (Sept. 21, p. 438). (1) The lack of security in movement of abduction is either due to incorrect use of the limb or lack of confidence, as a patient with a ten-inch stump should be able to achieve this without undue effort providing body weight is taken on sound limb. (2) Ability to dance on an artificial limb is purely a matter of confidence. The number of people that can do this bear out the statement, and it does not depend on any particular type of suspension or limb. (3) The triangular shape of bucket was adopted especially for the fleshy type of stump, to remodel stump and prevent rotation. (4) Making an artificial limb to pair with the sound limb is a complex problem, since the sound limb changes shape with the use of the muscles, also there have to be allowances for inclusion of mechanical joints. (5) The symmetrical shape of the knee is necessary because of the rigid materials used. Any variation from a circle allows a gap between the edge of shin and the knee, which is a trap for clothing, and can not only cause damage to clothing, but any clothing getting caught up can throw the person backwards and easily cause an accident. (6) Regarding adjustability to various shoe-heel heights, one has to know limbs to consider this point and know the mechanical disadvantages which operate with all types of limbs. Also, one of the most necessary improvements required in artificial limbs is that of raising the centre of gravity, to give a limb that can be used with less muscular effort. Therefore, any extra gadget or additional weight in the region of the foot and ankle is contraindicated. (7) The most justified criticism of the present limb is the glitter of the enamel. This is one point that should be, and could be, overcome in a comparatively easy manner, by using matt finish enamel or matt rubber surface, which would also have the advantage of deadening mechanical noise.

Effects of Penicillin Lozenges

Dr. A. D. BELLIOS (Wimbledon) writes: Within the last month I have had two cases of gingivitis following the use of penicillin lozenges in children. Each case was precisely similar. Both were mild cases of tonsillitis with pyrexia. I prescribed mist. acetylsal. and penicillin lozenges. Within two or three days both children were normal so far as the tonsillitis was concerned, but their gums became alarmingly swollen and fleshy, and bled easily. I assumed at the time that I was dealing with a streptococcal gingivitis and ordered a penicillin paint made up with magnesium hydroxide. This was used every three hours, and the penicillin lozenges continued. Both cases cleared up on this treatment in about five days.

Dr. E. J. BRADLEY (Margate) writes: I recently had penicillin treatment by inhalation: first 800,000 units spread over ten days; then 1,000,000 units concentrated into five days. On both occasions soreness, dryness, and cracking of the lips and nostrils were produced. The tongue also became sore and tender, but no actual ulcer appeared. There was considerably more irritation while using penicillin made by one firm than with that made by another; and incidentally there is a marked difference in the smell of the two brands.

Herpes and Varicella

Dr. GEORGE ARMOUR writes from Woodhall Spa: I submit the following unusual clinical case of herpes associated with chicken-pox in two contacts in a remote, isolated Lincolnshire farmstead. Mrs. X developed herpetic vesicles on the right anal margin with a few slight scattered lesions on the right buttock (corresponding to the distribution of the right inferior haemorrhoidal nerve) on Oct. 7, 1946. On Oct. 23 her son aged 32 developed widely distributed chicken-pox, and on the following day her other son aged 23 developed an even more widely distributed similar rash. The house is very remote and completely isolated, and being harvest-time none of the occupants had left the purlieu of the farm and no contact had been possible except through occasional tradesmen. On careful inquiry no case of chicken-pox could be traced within a radius of fifteen miles. The period of incubation appears most significant.

Missing Medical Books

Mr. A. J. JOHNSTON-WILSON has written from the Department of Printed Books, British Museum, W.C.1, with reference to the severe losses suffered by the British Museum from enemy action. The section containing medical books was the one most seriously affected. The losses include both foreign and English works and are particularly serious among books published in the late part of the last century and the early part of this century. Mr. Johnston-Wilson would gladly inform any member who has books which he is willing to give to the British Museum whether they are among the losses and particularly required. One of the publications wanted is *Historic Notes on Canadian Medical Lore*, being lecture memoranda published in Toronto in 1906.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 16 1946

THE NATIONAL HEALTH SERVICE: REPORT OF NEGOTIATING COMMITTEE

A.—A SUMMARY OF THE NATIONAL HEALTH SERVICE ACT

1. The Act places a general duty upon the Minister of Health to promote the establishment in England and Wales of a free, comprehensive health service designed to secure improvement in the physical and mental health of the people, and the prevention, diagnosis, and treatment of illness.

The Act deals only with the main structure of the service. Its detailed administration will be governed by Regulations to be made by the Minister under the powers which the Act confers upon him.

The main provisions of each part of the Act are summarized below.

Part I. Central Administration

2. The Minister of Health is given general responsibility for the organization of the service. To provide the Minister with professional and technical guidance there will be established a Central Health Services Council and Standing Advisory Committees.

The function of the Central Council is to advise the Minister upon such general matters as it thinks fit relating to the services provided under the Act or any services provided by local health authorities in their capacity as such authorities, and upon any questions referred to the Council by the Minister relating to those services.

3. The Council will consist of 6 ex-officio members, and 35 other members appointed by the Minister. The ex-officio members are the persons holding for the time being the offices of

President, Royal College of Physicians, London ;
President, Royal College of Surgeons, England ;
President, Royal College of Obstetricians and Gynaecologists ;
Chairman, Council of British Medical Association ;
Chairman, General Medical Council ;
Chairman, Council of Society of Medical Officers of Health.

The appointed members are:

(a) 15 medical practitioners, of whom 2 are to be selected for their knowledge of mental illness and mental defectiveness ;

(b) 5 persons with experience in hospital management (not medical practitioners) ;

(c) 5 persons with experience in local government (not medical practitioners) ;

(d) 3 dental practitioners ;

(e) 2 persons with experience in mental health services ;

(f) 2 registered nurses ;

(g) 1 certified midwife ;

(h) 2 registered pharmacists.

Before appointing these 35 members the Minister is required to consult such organizations as he may recognize as representative of the persons specified in paras. (a)-(h) above.

4. The Minister may, after consultation with the Central Council, by order vary the constitution of the Council.

5. The Minister is empowered to set up standing advisory committees to advise him and the Central Council on special aspects of the service. These committees will consist partly of members of the Council and partly of persons who are not members of the Council, and will be appointed by the Minister after consultation with the Council and with such representative organizations as the Minister may recognize.

In addition, the Central Council itself may appoint committees and the standing advisory committees may appoint subcommittees, and these bodies may include persons who are not members of the Council or standing advisory committees, as the case may be.

The function of a standing advisory committee is to advise the Minister and the Central Council upon such matters as it thinks fit relating to the services with which the committee is concerned, and upon any questions referred to it by the Minister or Central Council relating to those services. The committee may advise the Minister direct provided that it also informs the Central Council of the advice it has given, and the Council may express its views on that advice to the Minister.

6. The Central Council will make an annual report to the Minister on its work and that of the standing advisory committees, and the Minister is required to publish the report to Parliament, unless there is any reason of public interest for not doing so, when he may withhold it, in whole or in part, after consultation with the Council.

7. The Central Council will elect a chairman from its members. The chairman of a standing advisory committee will be elected by the committee. These bodies may regulate their own procedure.

Part II. Hospital and Specialist Services

8. It is made the Minister's general duty to provide hospital and specialist services of all kinds, including general and special hospitals, maternity accommodation, tuberculosis sanatoria, infectious diseases units, provision for the chronic sick, mental hospitals and mental deficiency institutions, accommodation for convalescent treatment and medical rehabilitation and all forms of specialized treatment. The services of specialists are to be available not only at hospitals, but also at health centres, clinics, and, if necessary on medical grounds, at the home of the patient.

Transfer of Hospitals to Minister

9. The ownership of the present public and voluntary hospitals, teaching and non-teaching, will pass to the

Minister. The existing premises and equipment and other assets, including, in the case of non-teaching hospitals, endowments, will be transferred to the Minister, together with existing liabilities. In the case of teaching hospitals, which are those hospitals so designated by the Minister, the endowments will be transferred to the new Boards of Governors.

Endowments

10. The Minister is to set up and administer a new hospital endowments fund, to which there will be transferred the endowments of non-teaching hospitals, with the exception of endowments of a capital nature given between the passing of the Act and the appointed day, which will be vested in the appropriate Hospital Management Committee. The disposal of the moneys in this fund is to be the subject of regulations made by the Minister. Broadly, these regulations are to provide that the fund shall be used, first, for discharging existing debts and liabilities attaching to the voluntary hospitals concerned. Secondly, the capital value of the fund is to be apportioned among the regional hospital boards and hospital management committees constituted under the Act. The income of each portion will then pass to those boards and committees to be used at the discretion of those bodies, subject to such general conditions as may be prescribed. A Regional Board or Hospital Management Committee will also be empowered to draw on its portion of the capital for any purpose which the Minister approves. The Minister, Boards of Governors, and Hospital Management Committees are required to secure so far as is reasonably practicable that the objects of the transferred endowments and conditions attached to them are not prejudiced.

11. The Regional Boards, Boards of Governors of teaching hospitals and Hospital Management Committees are empowered to receive gifts or legacies and to hold property on trust for purposes relating to hospital services, including research.

12. If necessary for the purposes of the new service, the Minister may acquire, either by agreement or compulsorily, hospitals other than those transferred to him under the Act, together with their equipment.

Any medical institution which may be set up in future can be acquired by the Minister if required for the purposes of the new service.

Administration

13. The Minister, while assuming general responsibility for these hospital and specialist services, will entrust their administration to Regional Hospital Boards, and to Boards of Governors in the case of the teaching hospitals.

The Minister will, by order, constitute Regional Boards and determine the areas over which their jurisdiction will extend. So far as practicable, these areas or regions must be based on University Medical Teaching Centres.

14. The function of the Regional Hospital Board is to undertake on behalf of the Minister the general administration of the hospital and specialist services in the region, subject to the Minister's general regulations and to such particular directions as he may give.

15. Each Regional Board is required to appoint, in accordance with a scheme to be approved by the Minister, local Hospital Management Committees, one for each large hospital or related group of hospitals forming a reasonably self-contained hospital service unit. The function of the Hospital Management Committee is to control and manage, on behalf of the Regional Board, a hospital or group of hospitals in accordance with regulations and such directions as may be given by the Minister or the Regional Hospital Board.

16. The *Regional Hospital Board* is to consist of a chairman appointed by the Minister and such other members so appointed as the Minister thinks fit, including:

(a) Persons appointed after consultation with the university with which the provision of hospital and specialist services in the area of the Board is to be associated;

(b) persons appointed after consultation with such organizations as the Minister may recognize as representative of the medical profession in the said area or the medical profession generally;

(c) persons appointed after consultation with the local health authorities in the said area; and

(d) persons appointed after consultation with such other organizations as appear to the Minister to be concerned.

The original members of the Board are also to include persons appointed after consultation with such organizations as the Minister may recognize as representative of voluntary hospitals in the area. It is laid down that at least two members of the Board shall be persons with experience in mental health services.

17. A *Hospital Management Committee* is to consist of a chairman appointed by the Regional Hospital Board, and such other members so appointed as the Board thinks fit, including:

(a) Persons appointed after consultation with any local health authority in the area;

(b) persons appointed after consultation with any Executive Council in the area;

(c) persons appointed after consultation with the senior medical and dental staff employed at the hospital or the hospitals in the area;

(d) persons appointed after consultation with such other organizations as appear to the Board to be concerned.

Although exercising functions on behalf of the Regional Hospital Board, the Hospital Management Committees will be legal entities and may sue or be sued in their own right.

Teaching Hospitals

18. The Act makes special provision for teaching hospitals. A teaching hospital is defined as any hospital or group of hospitals which appears to the Minister to provide for any University facilities for undergraduate or post-graduate clinical teaching, and which after consultation with the University concerned the Minister has designated as a teaching hospital.

19. The Minister is to constitute for each teaching hospital (or group) its own Board of Governors which will be responsible generally for administering the hospital on the Minister's behalf. The Board of Governors will consist of a chairman appointed by the Minister and such other members so appointed as the Minister thinks fit and of those members

(a) not more than one-fifth shall be nominated by the university with which the hospital is associated;

(b) not more than one-fifth shall be nominated by the Regional Hospital Board for the area in which the hospital is situated;

(c) not more than one-fifth shall be nominated by the medical and dental teaching staff of the hospital; and

(d) other persons shall be appointed after consultation with such local health authorities and other organizations as appear to the Minister to be concerned, including, in the case of the original members of the Board of Governors of a teaching hospital designated before the appointed day, the governing body of any voluntary hospital comprised or to be comprised in the teaching hospital.

Medical and dental schools are not to be transferred to the Minister or to the Board of Governors of the teaching hospital with which they are associated. The governing bodies of these schools will continue to own and administer their property and the Act provides for the transfer of any existing hospital property held for school purposes to these Governing Bodies.

Private Accommodation in Hospitals

20. The Minister is empowered to provide separate paid accommodation at hospitals within the service for private patients who are prepared to pay the whole cost of private maintenance and attendance. Specialist and general practitioners who are members of the staff of a hospital within the service, whether in an honorary or paid capacity, will be able to treat private patients in such accommodation and to charge fees subject to a maximum scale which will be fixed by regulations made by the Minister. Where there are single rooms or small wards in hospitals the Minister is empowered to make them available to patients who wish to buy greater privacy by paying the extra cost of the accommodation involved. The provision of such accommodation for private patients is subject to the over-riding right of other patients to be admitted to it without payment if medical considerations urgently require it.

Hospital Staff

21. The staffs of all hospitals in the service will be in the employment of the Regional Boards or Boards of Governors of teaching hospitals, as the case may be. Regulations will be made by the Minister governing the qualifications, conditions of service and remuneration of all classes of hospital staff. Before making these Regulations the Minister will consult organizations representing the staffs concerned. Special Regulations are to be made relating to the appointment of hospital medical and dental officers. These Regulations will require the advertisement of vacancies and the constitution of Advisory Appointments Committees to make a selection of candidates from whom the appointments will be made by the Regional or Teaching Hospital Board.

Ancillary Services

22. The Minister is authorized:—

- (1) to provide a bacteriological service (including laboratories) for the control of the spread of infectious disease;
- (2) to provide a blood transfusion service;
- (3) to conduct or to assist research relating to the causation, prevention, diagnosis or treatment of illness or mental defectiveness.

Boards of Governors of teaching hospitals, Regional Hospital Boards, and Hospital Management Committees are also authorized to conduct research.

Part III. Health Services provided by Local Health Authorities

23. The provision of the services listed below will be a statutory duty of local authorities which for the purposes of this part of the Act are the County and County Borough Councils and are designated "local health authorities."

(a) *Health Centres*.—The provision, equipment and maintenance of health centres and of the necessary staff other than medical or dental practitioners;

(b) *Maternity and Child Welfare*.—The functions of existing welfare authorities which are not County or County Borough Councils will be transferred to the local health authorities, with a power of delegation for child-welfare only parallel to that empowered by the Education Act, 1944. The specialist and institutional aspects of maternity will be the responsibility of the regional hospital board;

(c) *Domiciliary Midwifery*.—A domiciliary midwifery service. Local health authorities will become the local supervising authorities under the Midwives Acts. The section of the Midwives Act, 1936, which enables the Minister to prescribe conditions subject to which fees are to be payable to medical practitioners called in by midwives, is amended to empower the Minister to prescribe conditions as to the qualifications of such medical practitioners;

(d) *Health Visiting*.—The provision of health visitors for home visiting for the purpose of giving advice as to the care of young children, persons suffering from illness and expectant or nursing mothers, and as to the measures necessary to prevent the spread of infection;

(e) *Home Nursing*.—Provision for the attendance of nurses on persons who require nursing in their own homes;

(f) *Vaccination and Immunization*.—Arrangements for persons in the area to be vaccinated against smallpox or immunized against diphtheria. The local health authorities will have power to do the same for other diseases and a duty to do so if directed by the Minister. The present law on compulsory vaccination is repealed. In making their arrangements local authorities are required to give medical practitioners providing general medical services under the Act the opportunity of providing these vaccination and immunization services;

(g) *Ambulance Services*.—The provision of ambulances and other means of transport.

24. In addition, local health authorities will be empowered to provide home help services and to make arrangements "for the purpose of the prevention of illness," and for the care and after care of persons suffering from illness or mental defectiveness.

25. Each local health authority is required within a specified period to submit to the Minister its proposals for carrying out the requirements of the Act. The proposals must also be conveyed to the Regional Boards and Boards of Governors, to the Executive Council, to any voluntary organization which is providing similar services in the area and to every local authority whose area forms part of the area covered by the local health authority. Any of these bodies may make recommendations to the Minister for modifying the proposals, provided that copies of such recommendations are sent to the local health authority. The Minister may approve the local health authority's proposals with or without modifications, and it will be the duty of the authority to carry out the scheme as approved.

Statutory Health Committees

26. Local health authorities will be required to appoint statutory health committees and to refer to them all matters relating to the discharge of their functions under the Act other than the power to borrow money or to levy rates. The health committee may establish subcommittees at their own discretion and appoint by co-option non-members of the committee or subcommittee, subject to the proviso that a majority of the committee or subcommittee are members of the authority.

Part IV. General Medical and Dental Services, Pharmaceutical Services, and Supplementary Ophthalmic Services

Executive Councils

27. This part of the Act covers personal health services provided by general medical practitioners ("general medical services") and dentists and the supply of drugs, medicines and appliances. The duty of arranging for the provision of these services is placed upon new local bodies to be called executive councils, one of which will be established for the area of each county or county borough; at the Minister's discretion a single executive council may be established for the area of two or more local executive councils. The executive council is to consist of thirteen members appointed by the Minister and local authorities and twelve appointed by the professions as follows:

(a) A chairman and four members appointed by the Minister;

(b) eight members appointed by the local health authority for the area of the executive council;

(c) seven members appointed by the Local Medical Committee;

(d) three members appointed by the Local Dental Committee;

(e) two members appointed by the Local Pharmaceutical Committee.

28. The Minister has power to vary the constitution of an executive council or to establish a joint committee for the area of two or more executive councils to exercise some but not all of the functions of an executive council.

29. The main function of the executive council is to enter into contract with general medical practitioners, with dental practitioners, and with pharmacists for the provision (at a health centre or otherwise) of general medical, dental, and pharmaceutical services in accordance with regulations to be made by the Minister. The regulations are to include provision for

(a) the preparation and publication of lists of persons who undertake to provide these services;

(b) conferring a right on any person to choose the medical or dental practitioner by whom he is to be attended, subject to the consent of the practitioner so chosen and, in the case of medical services, to any prescribed limit which may be placed on the number of patients to be accepted by any practitioner;

(c) the distribution or allocation among medical practitioners who enter into contract with the executive council of persons who desire to obtain general medical services but who do not choose a medical practitioner or have been refused by the practitioner chosen;

(d) the issue of medical certificates.

30. Executive councils are also required to make arrangements with medical practitioners and opticians having the prescribed qualifications for sight-testing and the supply of optical appliances. Those services are referred to as "supplementary ophthalmic services" and their provision by executive councils is without prejudice to the ophthalmic services, clinic and other, to be provided by regional boards as part of the hospital and specialist arrangements. The Minister, however, is empowered to abolish the supplementary scheme administered by the executive councils as soon as he is satisfied that adequate ophthalmic services are available through the hospital and specialist service provided under Part II of the Act.

31. The Minister has wide powers to make regulations with regard to the procedure of executive councils, including the appointment of committees, which may consist wholly or partly of members of the council, and the delegation of functions to such committees.

Control of Distribution

32. Only medical practitioners who are engaged in medical practice (otherwise than as paid assistants) are entitled as of right to provide general medical services under the Act. This right is conditional upon the practitioner making application before the appointed day* to the executive council of any area in which he is practising to be included in the list of practitioners undertaking to provide general medical services for persons in that area.

33. After the appointed day any doctor who wishes to join the public service for the first time or, if he is already in it, to go to and practise in a new area will be required to obtain the consent of the Medical Practices Committee—a new central body appointed by the Minister. This body is to consist of a chairman (a medical practitioner appointed by the Minister) and eight other members of whom six shall be medical practitioners and at least five of whom are actively engaged in medical practice. The only ground for refusal of the Medical Practices Committee's consent is that the number of practitioners undertaking to provide general medical services in the area or part of it concerned is already adequate.

34. When a practice becomes vacant or when, in the opinion of the Medical Practices Committee, there is a need for additional practitioners in a particular area and the

number of applicants exceeds the number of vacancies, the Medical Practices Committee will select the person(s) whose application(s) is (are) to be granted and will refuse the other applications. Before making its selection the Medical Practices Committee is required to consult the executive council concerned and that body, before expressing its views on the person(s) to be selected, is required to consult the Local Medical Committee for the area (i.e., the Committee recognized by the Minister as representative of the local medical profession). Although the Medical Practices Committee is precluded from refusing the application except on the ground that there is an adequacy of practitioners, it may grant an application subject to the condition that the applicant is excluded from practising in a specified part or parts of an area.

35. The medical practitioner whose application has been refused or granted conditionally has a right of appeal to the Minister. The Minister may, if he allows the appeal, direct either that the application shall be granted in addition to the applications already granted or that it shall be granted instead of such one of those applications as the Minister may specify. The Medical Practices Committee and, in appeal cases, the Minister are to have regard to the wishes of an applicant to practise with other practitioners in an area, to any desire expressed by existing practitioners to take an applicant into practice, and special regard to family relationships.

Prohibition of Sale of Medical Practices

36. Section 35 of the Act makes it unlawful to sell the goodwill or any part of the goodwill of the practice of a doctor entering the public service on or after the appointed day. Thereafter, a practitioner buying or selling such goodwill is liable to criminal proceedings and, if found guilty, to imprisonment of up to three months and/or a fine up to such amount as will secure that he derives no benefit from the offence and a further amount of £500. This prohibition, however, does not cover the case of a medical practitioner whose name has ceased to be on the list of any executive council and who practises in the area of an executive council in whose list his name has never been entered.

A prosecution for an offence under this section can only be instituted by or with the consent of the Director of Public Prosecutions and a person so charged will be entitled to trial by jury at Quarter Sessions or Assizes.

37. There are enumerated in this section of the Act a number of transactions, any one of which is deemed for the purposes of the Act to be the sale of the goodwill of a medical practice. For example: (1) if an assistant is employed for substantially less remuneration than his services "might reasonably have been expected to be worth" and subsequently becomes a partner of his employer, an offence is committed; (2) if doctors in the service are in partnership and agree to share in unequal proportions the income of the partnership they will be liable to be prosecuted unless it is held that the partner who takes less than the other(s) is receiving substantially less than his services might reasonably have been expected to be worth at the time when the agreement was made; (3) a doctor's widow who sells his house to a practitioner for substantially more than the sum the house might have fetched if it had not been used for practice purposes commits an offence.

38. Subsections 9 and 10 of Section 35 of the Act give a medical practitioner or his personal representative an opportunity of ascertaining in advance whether a proposed transaction in the opinion of the Medical Practices Committee involves the sale of goodwill. If this Committee considers that the transaction does not involve the giving of any consideration in respect of goodwill it is required to issue to the applicant a certificate to that effect. Where a transaction results in a person being charged with an offence under this section of the Act, it is a defence to the charges to prove that the transaction was certified by the Medical Practices Committee unless the Court holds that the applicant for the certificate failed to disclose to the

* "Appointed day" means such day as His Majesty may by Order in Council appoint, and different days may be appointed for the purposes of different provisions of the Act.

Committee all the material circumstances or made any misrepresentation—in which case the Court may disregard it.

Where a medical practitioner practises in partnership, the term "goodwill" is to be considered as referring to his share of the goodwill of the partnership practice.

Compensation

39. The Act makes it unlawful to sell the goodwill of the practice of a doctor entering the public service after the appointed day. Doctors who join the service at the outset will be entitled to compensation in respect of the loss incurred through being unable thereafter to sell their practices. The doctor who because of age or infirmity or both does not enter the service on the appointed day will be entitled to compensation just as if he had entered. Doctors who join the service after the appointed day will not qualify for compensation.

The practice of any doctor who dies or retires from practice between the passing of the Act and the appointed day, which has not been sold in the meantime, will qualify for compensation. If compensation is paid the practice will be regarded as having come within the service at the appointed day.

40. The aggregate amount of compensation for which provision is made in the Act is £66,000,000 and this sum will be apportioned between England and Wales on the one hand and Scotland on the other. The sum

(a) is based on the Government's estimate that 17,900 principals will enter the National Health Service;

(b) will not be subject to increase if in fact more than 17,900 principals so enter;

(c) will be subject to reduction if the number of principals so entering is below 17,700; the reduction for each principal in defect of 17,700 to be 1/17,900 of £66,000,000.

41. Regulations will govern the detailed method of apportioning the global sum among the doctors entitled to compensation and the manner and times at which it is to be claimed and paid. The Minister is required to consult such organizations as he may recognize as representing the medical profession before making these regulations. The regulations are to provide that as a general rule compensation will not be paid until the retirement or death of the medical practitioner concerned, whichever first occurs. In the meantime interest on the compensation due at the rate of 2½% per annum will be paid in respect of the period from the appointed day until the time when the compensation is paid. In exceptional circumstances the compensation payment may be made earlier and the Minister has made it clear in his White Paper (Cmd. 6761) and in public announcements that the exceptional circumstances will include cases where hardship (e.g., through outstanding debts in connection with the practice) would otherwise arise.

Pharmaceutical Services

42. Executive councils will make arrangements for the supply of drugs, medicines, and appliances to persons in their area who are receiving general medical services, if ordered by a medical practitioner rendering those services. It appears that a patient will not be able to obtain drugs, medicines, and appliances under this arrangement unless they are ordered by a practitioner who has joined the service.

General Dental Services

43. All dental practitioners who undertake to provide general dental services under the Act will be in contract with an executive council. Their position will be generally analogous to that of medical practitioners on the executive council list save that there are no provisions with regard to the prohibition of the sale of goodwill or compensation for that loss; neither does the clause regulating the distribution of medical practitioners who enter the service apply to dental practitioners who enter the service.

Disqualification of Practitioners—the Tribunal

44. A special tribunal is to be set up to investigate cases where representations are made either by an executive council or, if the tribunal thinks fit, by any other person that the continued inclusion of any doctor, chemist, dentist, or optician in the lists drawn up by the executive council would be prejudicial to the efficiency of the service. The tribunal will consist of a chairman, who must be a practising barrister or solicitor of not less than ten years' standing, appointed by the Lord Chancellor, and will in each case include a member of the same profession as the person who is the subject of the inquiry and one other member. The "other member" will be appointed by the Minister after consultation with such associations of executive councils as he may recognize as representative of those bodies. The "professional" member will be one of a panel of six persons appointed by the Minister after consultation with such organizations as he may recognize as representative of the several professions concerned. The panel will consist of a medical practitioner, a dental practitioner, a registered pharmacist, a medical practitioner practising as an oculist, a sight-testing optician and a dispensing optician. Regulations will provide that the practitioner who is the subject of an inquiry shall have the opportunity of being heard in person, of being represented by counsel, solicitor or otherwise, of calling witnesses and producing other evidence, and of requesting that the hearing shall be in public.

45. The tribunal is bound to inquire into a case in which representations are received from an executive council, but where representations emanate from any other source the tribunal has discretion as to whether an inquiry should be held. Where the tribunal is satisfied that the continued inclusion of a person in any list to which the representations relate would be prejudicial to the efficiency of the service, it will direct the executive council concerned to remove from that list the name of the doctor, dentist, chemist, or optician. Where the tribunal so decides, a similar direction can be applied to all lists in all areas. The practitioner concerned may appeal to the Minister from any direction of the tribunal and the Minister may confirm or revoke that direction. When a practitioner's name is removed from the list or lists in question, he is disqualified for inclusion in any list to which the direction relates until such time as the tribunal or the Minister directs to the contrary. A practitioner who has already been disqualified from participation in the present National Health Insurance Scheme and whose disqualification has not been removed before the appointed day will not be entitled to participate in the new service.

Powers of Minister where Services are Inadequate

46. If the Minister is satisfied, after such inquiry as he may think fit, that the services provided by doctors, dentists, or chemists in any particular area are not adequate, he is empowered to take such steps as he considers necessary to secure an adequate service.

Postgraduate Courses

47. The Minister is empowered to arrange with universities and medical and dental schools for the provision of refresher courses for doctors, dentists, and others in the service and to contribute towards the cost of these services and the expenses of practitioners attending them.

Disputes

48. Any dispute arising under this part of the Act or under any regulation made under this part of the Act, whether between an executive council and a person receiving services or between an executive council and a local health authority as to the conduct of a health centre, is to be referred to and decided by the Minister.

Part V. Mental Health Services

49. The Act transfers to the Minister of Health the present administrative functions of the Board of

Control in regard to mental health, the Board retaining only its quasi-judicial functions connected with the liberty of the subject. The general transfer of hospitals to the Minister includes the present mental hospitals and mental deficiency institutions. The main mental treatment and mental deficiency services are to be part of the new hospital and specialist arrangements under the Act. Local health authorities, however, are given responsibility for the ascertainment of mental defectives and their supervision when they are living in the community, and for the initial proceedings for placing under care those who require treatment under the Lunacy and Mental Treatment Acts.

Part VI. General

50. This part of the Act deals with financial arrangements and miscellaneous administrative matters, the more important of which are set out below:

(a) Finance

Except that certain charges may be made for the provision and renewal of appliances and for accommodation in private wards the service will be free to all who care to use it. The Exchequer will be responsible for the full cost of the hospital and specialist services and of the general practitioner, dental, ophthalmic, and pharmaceutical services together with the cost of central administration and will also pay approximately one-half of the cost of the various services to be administered by the local health authorities.

(b) Default Powers of Minister

If in the Minister's opinion any of the various bodies constituted under the Act have failed to carry out any of their functions under the Act or to comply with any of the regulations or directions he may, after inquiry, declare that body to be in default and direct them as to the time and manner in which the default is to be remedied.

(c) Qualifications, Remuneration, and Conditions of Service of Officers

These will all be governed by regulations to be made by the Minister.

(d) Superannuation

The Minister has power to make regulations granting superannuation benefits on a contributory basis to officers of the various bodies constituted under the Act and to medical practitioners and dental practitioners providing general medical or dental services.

(e) Transfer and Compensation of Officers

The Act requires regulations to be made providing for the transfer to the appropriate authority under the new service of officers employed immediately before the appointed day by hospitals, insurance committees, and local authorities. In the case of honorary officers of a hospital, the position is obscure as the transfer of these officers is subject to such exceptions and conditions as the Minister may prescribe. Compensation will be subject to certain exceptions or conditions to be prescribed to officers whose functions are transferred and to be provided by the Bill if they were previously employed whole-time and suffer loss of employment or discontinuation of emoluments or of superannuation rights which is shown to be directly attributable to the Act. The amount of compensation and the basis of its ascertainment are not specified in the Act but are to be settled by regulations.

Regulations and Orders

51. A wide field remains to be covered by Regulations and Orders which the Minister is empowered to promulgate by the Act. All Regulations to be made under the Act are subject to Parliamentary control, but unless there is provision to the contrary Orders are not subject to Parliamentary control. Parliamentary control is exercised in two ways:

(1) by affirmative resolution; regulations subject to this are ineffective until the House has positively approved them;

(2) by negative resolution; regulations subject to this, though required to be laid before Parliament immediately they are made, become operative at once and, unless Parliament within forty days resolves that they be annulled, have statutory effect as if they were incorporated in the Act.

52. Of the Act's 80 clauses and 10 schedules, 40 confer on the Minister the power to make regulations or orders. The only regulations in the National Health Service Act which require an affirmative resolution of Parliament before they become operative are those dealing with (i) superannuation and (ii) the transfer and compensation of officers of hospitals, local authorities, and insurance committees.

53. Among the matters, many of them of fundamental importance, to be settled by regulations which do not require an affirmative resolution are:

(a) the control and management of the Hospital Endowments Fund;

(b) the functions of Regional Hospital Boards, Boards of Governors of Teaching Hospitals, and Hospital Management Committees;

(c) the appointment of medical and dental staffs of hospitals;

(d) the arrangements to be made by executive councils with doctors, dentists, opticians, and pharmacists for the provision of services to patients;

(e) the functions of executive councils in relation to filling vacancies in medical practice and the procedure for applications to the Medical Practices Committee and for appeals to the Minister;

(f) the extent to which executive councils shall consult with Local Medical, Pharmaceutical, and Dental Committees;

(g) the apportionment of the compensation global sum and the manner and time at which claims and payments are to be made;

(h) the procedure of the tribunal dealing with the disqualification of practitioners;

(i) the arrangements for the use of health centres by medical and dental practitioners;

(j) the qualifications, remuneration, and conditions of service of officers;

(k) the appointment, tenure of office, and payment of:

(i) members of the Central Health Services Council and standing advisory committees;

(ii) members of Regional Hospital Boards, Hospital Management Committees, Boards of Governors of Teaching Hospitals and of committees of those bodies and the procedure of those bodies;

(iii) members of executive councils and of committees of those councils, their officers and procedure;

(iv) members of the Medical Practices Committee;

(v) members and officers of the Tribunal;

(l) the recovery of charges for certain appliances and special dental treatment;

(m) grants to local health authorities;

(n) payments to Regional Hospital Boards, Boards of Governors, executive councils, and other bodies.

54. Orders are administrative acts of the Minister and do not come before Parliament in either of the ways applicable to Regulations, unless the Act so specifies.

The only Orders which the Act specifies as being subject to a negative resolution are those

(1) varying the constitution of the Central Health Services Council;

(2) determining the areas for which the Regional Hospital Board will be responsible;

(3) amending or repealing local acts and charters which are redundant or inconsistent with the Act.

55. The matters on which the Minister has power to make Orders which are not subject to Parliamentary review include:

- (a) the constitution of standing advisory committees of the Central Health Services Council;
- (b) the constitution of Regional Hospital Boards;
- (c) the designation of hospitals as teaching hospitals and the constitution of Boards of Governors;
- (d) the constitution of joint boards for the areas of two or more local health authorities;
- (e) the constitution of a single executive council for the areas of two or more local health authorities;
- (f) the variation of the constitution of a local executive council;

B.—THE PROFESSION AND THE ACT

56. Prior to the publication of the National Health Service Bill, the Negotiating Committee of the profession formulated and published a series of principles in which were expressed in general terms the basic tenets of the profession on the subject of the organization of the country's medical services. These principles are as follows:

I. The medical profession is, in the public interest, opposed to any form of service which leads directly or indirectly to the profession as a whole becoming full-time salaried servants of the State or local authorities.

II. The medical profession should remain free to exercise the art and science of medicine according to its traditions, standards, and knowledge, the individual doctor retaining full responsibility for the care of the patient, freedom of judgment, action, speech, and publication, without interference in his professional work.

III. The citizen should be free to choose or change his or her family doctor, to choose, in consultation with his family doctor, the hospital at which he should be treated, and free to decide whether he avails himself of the public service or obtains the medical service he needs independently.

IV. Doctors should, like other workers, be free to choose the form, place, and type of work they prefer without governmental or other direction.

V. Every registered medical practitioner should be entitled as a right to participate in the public service.

VI. The hospital service should be planned over natural hospital areas centred on universities in order that these centres of education and research may influence the whole service.

VII. There should be adequate representation of the medical profession on all administrative bodies associated with the new service in order that doctors may make their contribution to the efficiency of the service.

57. An examination of the Act in relation both to these principles and to more detailed expressions of policy reveals wide divergences between the provisions of the Act and the principles of the profession.

58. The profession is opposed to any development which tends to convert its members into full-time salaried servants of the State or local authorities. Government speakers have confirmed that a full-time salaried service is their objective, although they admit that such a service is inconsistent with free choice of doctor and not practicable at the present time.

59. Under the proposals of the Act consultants and specialists will become salaried officers of regional bodies appointed by the Minister, undertaking all their hospital work in hospitals owned by the State. General practitioners, no longer owning the goodwill of their practices, will be, to an extent yet to be determined, salaried employees of the State through local executive councils.

60. The profession has urged that there should be proper co-ordination and correlation of the country's medical services, both centrally and locally. Central departmental responsibility for health services remains divided amongst a number of different departments. Locally, the Act estab-

(g) the constitution of a joint committee for the area of two or more executive councils for the purpose of exercising some, but not all, of the functions of the executive council;

(h) the termination of the arrangements for the provision of supplementary ophthalmic services by an executive council;

(i) the exercise of default powers against local health authorities and any of the bodies constituted by the Act—the various hospital bodies, executive councils, and others—if they are not carrying out their functions or failing to comply with any regulations or directions relating thereto;

(j) the acquisition compulsorily of land required by the Minister for the purposes of the Act.

lishes not one but three administrations with insufficient co-ordination between them.

61. The hospital provisions, although creating what the profession has long desired—a powerful regional organization—may tend to destroy local interest and initiative and so affect adversely the capacity of a hospital for innovation and experiment, its power to attract nursing and other staff and the confidence of the local people in their local hospital.

62. In the field of general practice the profession has expressed the views:

(1) that general practitioners should retain the goodwill of their practices;

(2) that there should be no governmental control over doctors in regard to the areas in which they practise;

(3) that, except where special circumstances justify it, remuneration should be by capitation payments in proportion to the number of persons on a doctor's list.

The Act provides for the abolition of the custom of buying and selling general practices and for the establishment of a machinery of negative direction over the movement of general practitioners, while the profession maintains that the ownership of goodwill is essential to the continued freedom of the general practitioner. This abolition is regarded as a first and substantial step to a State salaried service while the system of "negative direction" which is proposed is an unjustifiable and unnecessary interference with the freedom of the doctor. Any necessary improvement in the distribution of doctors can be achieved on the existing basis of general practice.

63. The abolition of the custom of buying and selling practices creates more problems than it solves. An inevitable consequence of abolition is that the sale of practices for which compensation is paid should be illegal. But in addition to such prohibition the Act contains a series of definitions of offences so wide in their scope and so abstruse in their terminology as to be likely to be unjust in their application, despite the provision for some measure of protection by registration.

64. Though it appears to be contemplated that practitioners will work in partnership, such partnership will involve the risk of prosecution in every case in which the partners agree to share the income in unequal proportions, unless they obtain in advance a certificate from the Medical Practices Committee. The Act gives no guidance as to the basis upon which the services performed by any partner should be estimated or as to the factors which may properly be taken into account, except that regard is to be paid to the circumstances at the time when the agreement was made.

65. In the case of an assistant who subsequently succeeds to the practice of his principal, the principal is deemed to have sold the goodwill of his practice to the assistant, if the remuneration paid to the assistant was substantially less than his services might reasonably have been expected to be worth.

66. Even though the global compensation sum of £66,000,000 includes no allowance for the loss of goodwill in relation to doctors' houses, a practitioner who sells

his house to another practitioner with the knowledge that it will be used for practice purposes is liable to prosecution and, if convicted, to heavy fine and imprisonment if the purchase price is "substantially in excess" of the price which might reasonably have been expected if the house had not been used for practice purposes. It is impossible to foretell what interpretation a court might place on the words "substantially in excess." If premises are conveniently situated for a medical practice and have been used for a medical practice for many years a valuation of the premises upon the footing that they have never been so used would present a difficult problem to an expert valuer, and an even more difficult problem to a medical practitioner. A practitioner's widow or other personal representative (e.g., the Public Trustee or a Bank) would be confronted with similar difficulties when disposing of his house, bearing in mind that the most likely purchaser would be another medical practitioner.

67. Doctors who do not join the service by the appointed day will not qualify for compensation. The general practitioner must make this decision at the outset, before he has an opportunity of learning the wishes or inclinations of his patients. If he stays outside the service he may lose all his practice goodwill and will forfeit for ever his title to compensation. His patients will be penalized, as medicine and appliances will not be provided free under the Act to those patients who are not under the care of a doctor who has joined the service. It is difficult to reconcile this with the claim advanced in the Government White Paper that "all the service, or any part of it, is to be available to everyone. . . ."

68. The Minister's expressed determination to introduce a salary element in the remuneration of all general practitioners, whether special circumstances justify it or not, is further evidence of movement towards a full salaried service. A registered medical practitioner will not be able as of right to enter the new service.

69. The Act involves an excessive concentration of power in the hands of the Minister. He will appoint the Central Health Services Council and its committees. He will appoint the Regional Hospital Boards who will in turn appoint the Hospital Management Committees. He will determine by Regulation a wide variety of issues including mode and amount of remuneration. He will determine the issue of the continuance of a practitioner in the general medical service without a right of appeal to the Courts. The majority of Regulations the Minister makes will become law from the moment he makes them, subject only to their annulment by a Prayer in the House of Commons. He will deal with many important subjects by Orders which are not subject to Parliamentary control.

70. The profession has for years been pressing for a really satisfactory health and medical service. Although the constructive proposals of the profession are reflected in certain sections of the Act, yet in many important respects it is in substantial conflict with the views hitherto expressed by the medical profession, both in such general terms as in the statement of principles and in the more detailed terms of the expressions of policy of the representative professional bodies. The independence of medicine is at stake.

THE PLEBISCITE

We print below the letter being sent this week to every member of the medical profession by the Secretary of the B.M.A.

The Negotiating Committee was established to present to the Government the views of the medical profession as a whole on the medical services of the future. It consists of representatives of the British Medical Association, the English Royal Colleges, the Scottish Corporations, the Society of Medical Officers of Health, the Medical Women's Federation, the Association of Non-Teaching Voluntary Hospitals, and the Society of Apothecaries. This Committee has now sent to its constituent bodies a full report on the present position,

including a factual summary of the National Health Service Act and a commentary on the Act in the light of the views expressed by the organized bodies of the profession. The Committee, in transmitting this report, has asked its constituent bodies whether it is desired that the Negotiating Committee should proceed, if so invited, to discuss with the Minister of Health the regulations and orders to be made under the Act.

The Council of the British Medical Association has decided to put this question to every member of the medical profession for decision by plebiscite. In addition to the form of plebiscite, it sends you a copy of the Report of the Negotiating Committee referred to in the paragraph above. It urges every member of the profession to study the Report of the Negotiating Committee, to record an answer to the question put on the form of plebiscite, returning the form to me in the enclosed envelope within the next fortnight. It is appreciated that members of the profession over-seas will need a longer period of time. The results of the plebiscite, classified so as to show the voting of different groups of the profession, in different age groups, will be reported to the Negotiating Committee and published in the medical press. Whatever your views, please record your vote.

The Council of the Association believes it may be helpful to record briefly the decisions of the Representative Body of the British Medical Association on some of the more important issues. They are as follows:

1. There should be no control over doctors with regard to the choice of area in which they wish to practise. (Carried by 214 votes to 2.)
2. The transference of hospitals to State ownership is not approved. (Carried by 210 votes to 29.)
3. It is essential to the freedom of the patient and the profession that doctors should retain the goodwill of their practices. (Carried by 229 votes to 13.)
4. The remuneration of general practitioners should be by capitation payments in proportion to the number of persons on a doctor's list. (Carried by 209 votes to 8.)
5. Any doctor while practising privately either as a specialist or in general practice must enjoy the same privileges and rights and have all the facilities for treating his patients as are now held by all registered practitioners. (Carried unanimously.)

The divergences between these expressions of policy and the provisions of the Act are discussed in Part B of the Report of the Negotiating Committee.

The National Health Service Act does not require any doctor to enter the new service. Members of our profession, collectively or individually, are free to determine whether, in their view, the service created by the Act is one which they should enter or not. The issue immediately before the profession is whether it should or should not enter into discussions on the regulations, and this is the one which the Council of the Association puts to the profession as a whole for determination.

Yours faithfully,
CHARLES HILL.

HEARD AT HEADQUARTERS

Full Resources

The Council, at its meeting last week, set up a strong committee to consider the position of practitioners who, while desiring to act in full loyalty to the Association, are embarrassed by heavy financial commitments which make it particularly difficult for them, on the Association's request, to give up contract practice. It is above all things desired that the question in the plebiscite should be answered simply according to the views and convictions of the practitioner, uninfluenced by considerations of particular personal difficulty. The Council had specially in mind the middle-aged man with family and educational responsibilities. It is, of course, unlikely that in the event of "hostilities" there will be any catastrophic cessation of income, seeing that two-thirds of general practice, taking the country all over, is non-insurance practice and that even insurance practice in some

form or other must continue. But in every fight there are casualties, and here some will occur among the class just named who are not as fully armoured against adversity as others. All who enter a fight expect some loss, but what it is desired to guard against is exceptional loss falling upon a few.

The reassuring statement was made by the Treasurer and fully endorsed by the Council that in case of need the full resources of the Association would be available. The Emergency Guarantee Fund is fed from three sources: the guarantees of the National Insurance Defence Trust, of the British Medical Association, and of individual guarantors. Dr. Dain, at Exeter, drew the applause of his audience when he said: "We could to-morrow morning, if it were wanted, spend up to a million pounds." The committee is to examine and report on ways and means of assisting individual practitioners incurring hardship as a result of following the advice which may be given by the Association in connexion with the National Health Service.

A Busy Council

The November meeting of the Council was one of the busiest of recent years. There were several important debates, and several committees were set up to carry matters further. One committee was set up to investigate the provision for the care of the elderly and infirm—in two words, the chronic sick. Another was given the task of formulating for submission to the Ministry of Education proposals for the revision of the scale of fees for the medical treatment of school-children. The "closed shop" and the general question of trade unionism and the profession were assigned to another special committee. A fourth committee, as stated above, was the "hardship" or "ways and means" committee. Two important reports, one of them on the reform of the General Medical Council and the other from the Psychiatry and Law Committee recommending the abolition of corporal punishment, came on late in the day, and, a division of opinion developing on both these subjects, it was considered expedient to adjourn them to an extra meeting of the Council to be held on the second Wednesday of December. By that time it should be possible to announce the first results of the plebiscite.

Those Milk Certificates

Milk is the most innocent of fluids, but it has proved on many occasions to be highly controversial. Debates on clean milk have been marked by more acerbity than debates on apparently far more contentious subjects. At the Council meeting the question of milk came forward from a new angle—namely, the statement of the Ministry of Food given in the *Journal* of Nov. 2 concerning priority certification. Dr. F. Gray raised the question and pointed out that according to this statement it seemed to be assumed that one out of every three milk certificates issued by practitioners was dishonest. An odd thing that the same body of doctors who were issuing certificates honestly and competently during the war should, after the end of hostilities, go "haywire." A more likely explanation was that the people of this country, as long as the war lasted, hesitated to make their often rightful claims, but since the end of the war they had not had this hesitation, and practitioners, when medical reasons justified the claim, could do no other than endorse it. The real trouble, said Dr. Gray, was the incompetence of the Ministry of Food, which had miscalculated the amount of milk required both for priority and for ordinary consumers, and he protested against the profession's being made the scapegoat for a Government department. This feeling was endorsed by the Council in a resolution, but it was also urged strongly that there should be no cutting down of the needful ration for the sick and that the old also should have concessions.

Good Leadership

After presiding over a Council meeting lasting eight hours, Dr. Dain, the chairman, travelled to a large meeting of West Country practitioners at Exeter to address the first medical gathering following the passing into law of the National Health Service Act. He spoke for an hour in a large hall crowded in every part. The applause was hearty and no dissident or

doubtful voice was raised. Indeed, the proposer of the vote of thanks confessed that he himself had been a critic of the leadership of the Association, but he had now come round completely to an intense admiration for it as a result of what had taken place during these recent controversial months. Dr. Dain, he said, had been patient where patience was necessary, had been firm on crucial points, and, while alive always to the interests of the profession, had consistently related them to the wider interests of the public, with which they were not in disharmony.

Honour to Whom Honour . . .

Two men who have given long and outstanding service to the Association are to be recommended by the Council to the Representative Body for election to the Vice-presidency of the Association. They are Dr. J. C. Matthews and Dr. H. W. Pooler. Their names will be a worthy addition to a list which at the moment numbers fifteen and includes several famous veterans. Some well-known names also appear among the honorary secretaries who have recently relinquished office after distinguished service and have received the thanks of the Council. They include Dr. W. Paterson, Dr. Balfour Barrow, Dr. John Hunter, and Dr. J. Lewin, of the Willesden, Winchester, City of Edinburgh, and West Norfolk Divisions, and Dr. O. T. J. Clayre and Dr. F. A. Roper of the Southern and South-western Branches.

Names and Addresses

The new *Annual Handbook* of the B.M.A. for 1946-7 is again a miracle of compression. It contains everything the Branch or Divisional secretary needs to know, including the names and addresses of his 365 fellow secretaries, and while it gives this and a large amount of other information, it fits neatly into the pocket without spoiling the shape of the coat. Since the last edition a number of new officials have taken their place at headquarters, including two assistant secretaries, as well as the staff of the abstracting service, and their names are here set out. Another useful list is the names and addresses of the deans for postgraduate education for demobilized medical officers. In addition to this there is much about the membership of the Association, the rates of subscription, the constitution, and a list of the Association's publications, which now include seven special quarterly journals. Although the book is primarily for secretaries of Divisions and Branches, copies will be sent to individual members on request for as long as supplies are available.

Association Notices

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: an Ernest Hart Memorial Scholarship, of the value of £200, a Walter Dixon Scholarship of the value of £200 and four Research Scholarships, each of the value of £150. These Scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State Medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession. Each Scholarship is tenable for nine months, commencing on Feb. 1, 1947. A Scholar may be re-appointed for not more than two additional terms. A Scholar is not necessarily required to devote the whole of his or her time to the work of the research, but may hold a junior appointment at a university, medical school, or hospital, provided the duties of such appointments do not interfere with his or her work as a Scholar.

Conditions of Award. Applications

Applications for Scholarships must be made not later than Saturday, Dec. 28, 1946, on the prescribed form, a copy of which will be supplied on application to the Secretary of the

Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated.

Middlemore Prize

The Middlemore Prize consists of a cheque for £50 and an illuminated certificate, and was founded in 1880 by the late Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize in the year 1947 to the author of the best essay on: "The Aetiology and Treatment of Chronic Irido-cyclitis." Essays submitted in competition must reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, on or before Dec. 31, 1946. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1947.

Diary of Central Meetings

NOVEMBER

19. Tues. Undergraduate Subcommittee: (Film Committee), 2 p.m.

Meetings of Branches and Divisions

DORSET DIVISION

The 1946 B.M.A. Lecture was given to the Dorset Division by Mr. D. G. Wilson-Clyne on "Breech Presentation" on Oct. 24. About 40 members attended and Mr. Clyne was congratulated on the interest and clearness of his exposition.

GIBRALTAR BRANCH

The annual report of the Gibraltar Branch Council for 1945-6 says that the activities of the Branch have continued unabated. Seven meetings were held at the Colonial, Military, and King George V Hospitals, with a good average attendance of members and guests. At six of these papers were read and clinical cases demonstrated, and one was devoted to medico-political matters. A resolution expressing the confidence of the Branch in the efforts of the Council of the Association to negotiate with the Government over the National Health Bill was passed and conveyed to headquarters. Representations were successfully made to the Gibraltar Government to stop the illegal practice of ophthalmology by a foreign medical practitioner in the colony. The first post-war annual dinner was held at the Rock Hotel and was attended by a large number of members and guests.

Branch and Division Meetings to be Held

BERKS, BUCKS, AND OXFORD BRANCH.—At the Nuffield Institute, Oxford, Wednesday, Nov. 27, 3.30 p.m. Meeting of Branch Council. Agenda: Address by Dr. Agnes Kelynaek, Assistant Secretary, B.M.A.

KENT BRANCH.—(1) At County School for Boys, Hayes Lane, Bromley, Thursday, Nov. 21, 8 p.m. Discussion: National Health Service Bill. The speaker will be Dr. H. Guy Dain (Chairman of B.M.A. Council). (2) At Foresters Hall, High Street, Canterbury, Sunday, Nov. 24, 3 p.m. Discussion: National Health Service Bill. Mr. A. L. Abel will be the main speaker. All medical practitioners are invited to attend both these meetings.

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, Nov. 21, 7.15 p.m. Clinical Demonstration by Dr. J. R. Murray: The Differential Diagnosis of Early Schizophrenia. 8.45 p.m., address by Dr. R. Cove-Smith: Juvenile Rheumatism as a Social Problem.

SUNDERLAND DIVISION.—At the Sunderland Royal Infirmary, Thursday, Nov. 21, 3.30 p.m. Annual Address by Sir Stanford Cade: Present Day Therapy in Malignant Disease. 7.30 p.m. Annual Dinner.

WEST MIDDLESEX DIVISION.—At Myllet Arms Hotel, Perivale, Sunday, Nov. 17, 3 p.m. Dr. A. Maerac: The Referendum. All practitioners in the area of the Division are invited.

WEEKLY POSTGRADUATE DIARY

BLACKPOOL: VICTORIA HOSPITAL.—Thurs., 8 p.m. Dr. McAuley: Anaesthetic Problems in Severe Cases.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—Tues., 5 p.m. Dr. W. N. Goldsmith: Acneiform Eruptions.

MANCHESTER UNIVERSITY: PHYSIOLOGY THEATRE.—Tues., 4.15 p.m. Lloyd Roberts Lecture by Prof. Michael Polanyi, F.R.S.: The Foundations of Academic Freedom.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Erasmus Wilson Demonstrations, Tues., 5 p.m. Mr. J. T. Chesterman: Specimens Illustrating Intestinal Obstruction. Thurs., 5 p.m. Mr. V. Zachary Cope: Actinomycosis.

ROYAL SOCIETY OF MEDICINE

Section of Pathology.—Tues., 4.30 p.m. Laboratory meeting Westminster Hospital School of Medicine, S.W. Demonstrations: Prof. R. J. V. Pulvertaft: 1. Leisegang rings and antiseptics. Bacteriolysis and antiseptics. Dr. J. G. Humble: 3. Chloroform Specimens and spectra. 4. Heterotopic bone marrow in the lumen of the kidney in leukaemia. (a) Chronic myeloid leukaemia; Sub-acute lymphatic leukaemia. Dr. M. Haines: 5. Tuberculous selerosis. Dr. Hewitt: 6. Formation of optically active bodic bacterial cultures. Dr. E. Geal: 7. Demonstration of technique culturing *E. histolytica*. Dr. A. Morgan and Dr. G. Lumb: 8. Case of multiple aneurysms. Dr. P. Hansell: 9. The application of photography to pathology. Dr. D. Bunn and Dr. N. F. MacLagan: 10. Flocculation tests with electrophoretically separated serum proteins. Dr. A. Barham Carter and Dr. MacLagan: 11. Liver function tests in diseases not primarily hepatic. Dr. N. F. MacLagan: Liver function tests in jaundice; 13. Faecal urobilinogen estimations. Dr. MacLagan and V. R. Wheatley: 14. Determination of urinary pregnandiol. Dr. J. Eden: 15. Urinary pigments and creatinine relation to basal metabolic rate.

General Meeting of Fellows.—Tues., 5.30. Ballot for election to the Fellowship.

Section of Proctology.—Wed., 8.30 p.m. Presidential address by Mr. A. Hedley Whyte: Proctology—past and present.

Section of Dermatology.—Thurs., 5 p.m. (Cases at 4 p.m.).

Section of Epidemiology and State Medicine.—Fri., 2.30 p.m. Discussion: Modern methods in the control of airborne infections. Opener: Dr. Robert Cruickshank. Followed by Dr. O. H. Lidwell, Mr. F. Courtney Harwood, and Dr. Joyce Wright.

Section of Paediatrics.—Fri., 5 p.m. (Cases at 4.15 p.m.).

EUGENICS SOCIETY.—At Royal Society's Rooms, Burlington House, Piccadilly, W.—Tues., 5.30 p.m. Prof. Tage Kemp (Director of the University Institute of Human Genetics, Copenhagen): Fifteen Years' Experience of Negative Eugenics in Denmark. All interested are invited to attend.

HUNTERIAN SOCIETY.—At Apothecaries Hall, Mon., 8.30 p.m. Discussion by Messrs. H. N. Linstead, M.P., A. Mortimer, and J. S. Walsley and Dr. G. H. Day: That the Advertisement of Proprietary Medicines is a Menace to the Public.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—Fri., 9 p.m. Dr. Maedonald Critchley: Sir William Gowers, A Biographical Study.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At London School of Hygiene and Tropical Medicine, Keppel Street, W.C.; Thurs., 8 p.m. Laboratory meeting. Various demonstrations will be given.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At West London Hospital, Hammersmith, W., Fri. (Nov. 15), 8.45 p.m. Clinico-Pathological Meeting.

POSTGRADUATE NEWS

A postgraduate course in cardiology will open on Thursday, Nov. 21, at 3.30 p.m., at the Liverpool and District Hospital for Diseases of the Heart, 34, Oxford Street, Liverpool.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BUNDER.—On Oct. 28, 1946, at 48, Holland Park, W.11, to Margaret (née Sweeney), M.R.C.S., L.R.C.P., wife of Rudolf Bunder, a son.

CORR.—On Oct. 25, 1946, at the North Lonsdale Nursing Home, Barrow-in-Furness, to Patricia (née Wheller), wife of Lieut.-Col. J. H. C. Corr, R.A.M.C. (No. 50 Civil Affairs Unit, Labuan, North Borneo), a son.

LESLIE.—On Nov. 1, 1946, at Philadelphia, U.S.A., to Kathryn (née Sobey), wife of Dr. James Watt Leslie, a daughter—Patricia Isobel.

PRIOR.—On Nov. 1, 1946, at 1, Dudley Street, Grimsby, to Eileen Mary (née Goronwy), wife of John R. Prior, a daughter.

DEATHS

HERAPATH.—On Nov. 4, 1946, Charles Edward Kynaston Herapath, M.C., M.D., of Bristol, dearly loved husband of Phyllis.

MUNRO.—On Oct. 20, 1946, at Woodlands, Nettleworth, Durham, Hector Munro, M.B., C.M. (Aberdeen), aged 78 years.

PROCEEDINGS OF COUNCIL

A report of the Proceedings of Council on Nov. 6 will be published in the Supplement of Nov. 23.

LONDON SATURDAY NOVEMBER 23 1946

PHYSIOLOGICAL REST*

WITH SPECIAL REFERENCE TO ARTHRITIS AND NERVE LESIONS AND
TO THE MANUFACTURE OF APPLIANCES

BY

NORMAN CAPENER, F.R.C.S.

FIG 1.—Shoulder platform splint—physiologically unsatisfactory.

In this country during the nineteenth century the outstanding exponents of the use of rest in the treatment of disease were John Hilton and Hugh Owen Thomas. The former in his Arris and Gale Lectures of 1859-61 coined the phrase "physiological rest," which following Hunterian teaching he called "natural therapeutics." Hilton aimed at dissociation of physiological activity from a diseased or injured limb. He emphasized the dependence of both growth and repair upon rest. Hugh Owen Thomas (1876) completed Hilton's argument by showing how rest should be used. Thomas is known to many as the designer of numerous splints that go by his name. But more important than this were the principles he taught for their application.

In this century Robert Jones achieved for Thomas the acceptance which was so largely denied him during life. Thomas overstated his case, yet for the conditions of his day the emphasis was needed just where he placed it, namely, upon "rest—enforced, uninterrupted, and prolonged." Conditions of medicine, as of life in general, have changed. Though Thomas's views need modification, he has important lessons for us now. While neither Hilton nor Thomas was an orthopaedic surgeon in the restricted modern sense, the ideas which they taught have resulted in the establishment of orthopaedics as a differentiated (not necessarily "specialist") field of medicine and surgery. In the aseptic evolution of technical

surgery it has been the appreciation of the meaning of physiological rest which has provided the orthopaedic principle. ("The ultimate basis of the existence of something."—O.E.D.)

Definition

Physiological rest as we understand it to-day is a controlled process, giving immobilization—while safeguarding functional restoration—of a part or the whole of the body in the position most favourable for the biological processes of growth and repair to the maximum extent required for these processes in the particular disease or injury being treated. Physiological rest is not necessarily absolute or uninterrupted rest, though for some period it may be so. Its purposes are to promote healing by reducing the local physiological demands of the limb, by avoiding the aggravation of pathological processes, and by bringing to bear upon the lesion the whole general metabolic resources of the patient.

It must be arranged so as to prevent the deforming influences of uncontrolled or unbalanced muscular activity, of muscular atrophy, and of gravity. Relaxation and restriction of muscular activity is modulated according to the disease. In some conditions rest will alternate rhythmically with movement, the relation of one to the other varying inversely as healing proceeds. While pathological conditions are being relieved by rest, no extrinsic pathological factors should be introduced. Local treatment must be planned within the most favourable general background for physical and psychological health.

FIG 2.—The adjustable Littler-Jones abduction splint. (Wingfield-Oxford type.)

* Abstracted from an Arris and Gale Lecture delivered at the Royal College of Surgeons on Jan. 3.

FIG. 3.—(a and b) The physiological position for the hand.
(c) A plaster moulded splint in this position.

The local positions and their duration vary according to the different conditions being treated. Physiological rest in some form is an important requirement in the treatment of such varied conditions as fractures, dislocations, acute and chronic arthritis, tuberculosis, osteomyelitis, peripheral nerve injuries, infantile paralysis, burns, and the lacerated hand; but each calls for particular modifications, all of which are covered by the definition as stated. In chronic deforming arthritis in particular there is scope for improvement—for a clearer realization of what could be done to relieve local disease, to improve general well-being, to prevent deformity, and to maintain or restore function. Furthermore, in all fields there is need for better knowledge of splint design, construction, and usage.

Arthritis

Whatever may be the cause of chronic deforming arthritis, it is necessary to emphasize the interrelation of the morbid change in joints with the spasm and atrophy of muscles, and conversely of the contributory effects of deficient muscular activity upon joint degeneration, and, furthermore, the aggravation that the local process provides for the whole constitutional disease. Therefore, no matter what medical or physical therapeutic measures are applied, most joints affected with arthritis pass at various times through phases of activity which require immobilization.

While joints are acutely inflamed the most perfect immobilization is necessary and must be carried out until the inflammatory process has subsided and muscle spasm is relieved. The subsidence of pain and the diminution of local tenderness, swelling, and irritability are important guides. Defects in the application of rest are, first, not giving adequate attention to the posture in which the joint is placed; secondly, not guarding against the ill effects of movement, friction, pressure, constriction, traction, and gravity; thirdly, imperfect timing of the duration or modification of rest and, consequently, failure

adequately to safeguard the maintenance or restoration of function when permissible.

For every normal joint there is a physiological position which is optimal for the average needs of the limb—a position in which its controlling musculature is able to exert its power to best advantage, a position in which muscles are poised for function and where none of the flexible capsular tissues is being stretched. The "physiological positions" of limbs are completely different from the so-called "anatomical positions," which merely provide standards of convenience and, clinically, are almost always unsuitable and indeed undesirable for treatment. The physiological position is not a fixed one but varies within a moderate range generally near the middle of the normal range of movement of the joint. The optimal position for the treatment of arthritic joints—modified from this physiological position—must be not only suitable for the pathological and therapeutic requirements but also such that if stiffness or ankylosis occurs it shall be in a position which will be best for function. In other words a nice compromise must be established between the optimal position for muscular competence and the later possible requirements of joint posture. These positions are enumerated in the following list:

Table showing the Optimal Positions for the Treatment of Arthritic Joints

Joint	Position	Remarks
Shoulder	Abduction 45° Flexion 30° External rotation 15°	Prevents stiffness in adduction; aids deltoid function; safeguards capsular integrity. The position is favourable for function in ankylosis
Elbow	Extended to about 100°	Safeguards the function of the elbow flexor muscles. If ankylosis is likely to occur modifications of the position recommended must be made according to the wishes of the patient, guided by his social circumstances and occupation. Where both elbows are involved one should be treated at a smaller angle
Forearm	Mid prone-supine position	Favours the restoration of either movement. If ankylosis occurs compensation for loss of pronation can be gained by abduction of the shoulder. Stiffness in supination is objectionable
Wrist	Extension 30°	The angle is measured upon the dorsum of the radius and of the third metacarpal
Digits and thumb	All joints flexed about 25° Abducted and opposed moderately	The hand as a unit is held in the position of semi-grasp, the thumb practically continuing the line of the lateral border of the radius, the phalanges of all digits in the position of natural relaxation—e.g., that assumed when the normal hand is loose at the side of the body. Capsular and ligamentous stretching is avoided. The vicious position of metacarpo-phalangeal hyperextension is avoided
Spine	Normal curves maintained	Flexion as well as torsion of the lumbar spine to be avoided
Hip	Abduction only of sufficient amount to compensate for true shortening Rotation nil Flexion 20°	In arthritis extreme degrees of true shortening of a lower extremity are unlikely to be found. Flexion permits sitting, if there is compensatory movement in the lumbar spine
Knee	Flexion 15°	Avoids posterior capsular stretching and resultant hyperextension instability. The competence of the quadriceps is adequately safeguarded
Ankle	Right-angle	If ankylosis appears inevitable the foot should be plantar-flexed 5° to 10° in men and a few degrees more in women to facilitate walking in high-heel shoes
Tarsal joints	Neutral as to inversion or eversion	While the arches of the foot should be preserved, it is better, should ankylosis be inevitable, to err in the direction of eversion, for the weight-bearing surface exposed to the ground is less likely to be troublesome than if the foot is inverted or everted
Toes	Maintain flexion of M.T.P. joints and extension of I.P. joints	Preserves intrinsic muscular activity; avoids metatarso-phalangeal subluxation and metatarsal pressure points

In my view these positions are worthy of acceptance universally as the standard "physiological positions." During the chronic stages of arthritic disease rest may still form a very important accompaniment of whatever other treatment is given. Here, however, there may be the added need to correct deformity. Finally, rest may even be used with the object of obtaining complete fixation or ankylosis of a joint, an end which may also be aided, of course, by surgical means.

FIG. 5.—Brian Thomas extensor appliance (Exeter model).

Lower Motor Neurone Lesions

All that has been said about muscular competence in arthritic disease applies also in the treatment of nerve lesions whether peripheral or poliomyelitic. There is indeed in the muscular phenomena associated with poliomyelitis a striking similarity to the muscular condition in arthritis. In the past it would appear that too great emphasis has been given to placing paralysed muscles in positions of greatest shortening, to the detriment of joint efficiency and of muscular re-education. An intermediate position is far better. Knowledge of the normal mechanism of maintaining physiological tonus (the simplest and gentlest type of reflex skeletal muscular activity) suggests this. Studies of the changes in denervated muscle (Tower, 1939; Bowden and Gutmann, 1944) indicate the same need, as well as the advisability of maintaining relative rest in good positions rather than absolute rest. The positions already listed are those suitable for the treatment of an extensive lower motor nerve lesion as in poliomyelitis. Even in the treatment of any individual peripheral nerve lesion the relevant positions indicated would be compatible with adequate protection of the paralysed muscles and suitable for muscular re-education. In nerve lesions the application of rest and support is associated where possible with substitution devices for replacement or assistance of deficient muscles.

Design of Orthopaedic Appliances

Physiological rest is far more than the fixation or splinting of limbs. It is perhaps unfortunate that the word "splint" has come to mean an immobilizing device, for originally a "splint" was something that permitted rather than restricted movement. In mediaeval times the movable sections of suits of armour—for example, at the elbow or knee—were called "splints."

Appliances are used for the following purposes: (a) Support; to oppose gravity. (b) Immobilization or limitation of movement. (c) The correction of deformity. (d) The mobilization of joints. (e) The substitution of defective muscular action. Appliances must be designed so as to fulfil these purposes with maximum comfort and convenience. This involves lightness and accessibility; smoothness of anatomical fit; adequate

FIG. 6.—Adaptation of same appliance for finger flexion deformities—e.g., ischaemic or arthritic.

FIG. 7.—Further modification of springs having "push" action for the treatment of metacarpo-phalangeal stiffness.

strength; simplicity of construction; and economical and speedy manufacture. Surgical appliance making has been in the past, and still is, in the hands of commercial craftsmen who have done splendid work, yet who are often divorced from adequate medical guidance. Control by the surgeon is greatly needed, and in order to bring the maximum good to the majority modern methods of manufacture should be more readily applied.

The greater mobility of populations necessitates the production of apparatus using standard parts which will receive servicing in one part of the country as in another, as in the case of the motor-car. In surgical appliance making there should be less conservatism.

Improved efficiency and economy could be achieved by an increased use of regionalization, and the setting up of workshops or the development of industries using similar materials with standard designs for certain appliances or portions thereof and with standard schedules for measuring and ordering. Standardization need not be an obstacle to initiative and advancement.

The wedding of mechanical efficiency to comfort in use is often a serious problem. The Thomas bed-knee splint, in spite of various later useful modifications, still remains as finally used by its inventor, a supreme example of the solution of this problem. Makeshift appliances are a particular anathema in orthopaedics, and with them "fitness for purpose" is "more honoured in the breach than the observance." There should be no excuse for the application to patients of appliances in the unhygienic, much-used, second-hand state so frequently found. Good plaster-of-Paris technique has made this unnecessary. Indeed, for most short-term requirements plaster-of-Paris, properly applied, provides the almost ideal material and the most readily available instrument of physiological rest. It is not necessary here to discuss this at length, although an illustration of the use of plaster in the treatment of arthritis in the hand is given.

FIG. 8.—A new device for the treatment of flexion contractures of the interphalangeal joints, using multiple strips of window-curtain springs.

FIG. 9.—The ulnar intrinsic spring splint.

elbow by means of a curved slotted rod with a bolt and nut permitting 90° variability in rotation. This appliance can be worn under the outer clothes and is equally suitable for wearing outside. Though in the model illustrated numerous straps are shown which distribute the weight of the apparatus, very few of these are essential. The lower part of the frame where it encircles the pelvis, instead of being made of metal rod, is fashioned from mild steel flat strip suitably padded to distribute pressure over a wide area. In some of the earlier versions of this Oxford modification pressure was experienced beneath the elbow, generally on the medial epicondyle or against the ulnar nerve. This difficulty has been overcome in a later model by dipping the framework downwards at this point. Here, therefore, is an appliance giving relative immobilization, and it is readily adjustable with splint benders because it is made of mild steel, thus making it possible to correct deformity. It is available for one side of the body only. Its chief defect is the presence of disagreeable vertical rods at the back and front of the trunk.

The Shoulder

A common appliance is the abduction splint used in the treatment of the stiff shoulder, in conditions due to neurovascular drag across the first rib, and for the support of the limb in injuries to the forearm and hand, etc. It is valuable in the correction and mobilization of deformity and for the support and re-education of weakened muscles. It is common to see the adaptation for these purposes of unsatisfactory appliances. In the one illustrated (Fig. 1) there is a mere platform with little adjustment: it fits merely where it touches and is uncomfortable and inconvenient.

The "Littler-Jones" frame (Fig. 2) is an improvement but in its original form did not provide a truly physiological position and lacked adjustability. At the workshops of the Wingfield-Morris Orthopaedic Hospital, Oxford, a great improvement was effected by division of the main frame at the elbow-joint and the addition of a forearm splint, articulating with the main frame beneath the

The Hand

In many ways the hand is at last receiving better care, particularly in fractures, wounds, and burns. The lessons from these fields should with modifications be applied to the treatment of arthritis. Various first-aid appliances of sheet metal are available, but none so far produced is satisfactory. In acute lesions of the interphalangeal joints, each digit has its own problems and must be treated very often individually. Plaster-of-Paris, which still supplies the most satisfactory material for immediate support, requires precision in application, and should have as much care devoted to it as a surgeon would expect to give to the application of a plaster jacket or spica.

I illustrate (Fig. 3) the physiological position for the hand and a plaster splint which with careful interdigital moulding will give some measure of individuality to the digits. The hand provides an example of the use of plaster moulds from which hard casts (Fig. 4) may be prepared upon which plastic material, such as leather or synthetic resins, may be moulded for more permanent appliances.

The problems of arthritis in the less acute states bear certain resemblances to those problems seen in peripheral nerve and vascular injuries, in which stiffness and deformation occur, the latter largely due to defective muscle balance and capsular contracture. Improvements in appliances for the hand have been made as the result of experiences with peripheral nerve injuries during the war. Some are illustrated (Figs. 5-9). To one particular splint I want to draw attention because it involves a principle which though not new could be applied probably to many other problems throughout the body. We are familiar with appliances which replace to some extent the toe-raising spring for paralytic drop-foot, and the M.R.C. elastic extensor appliance for radial-nerve palsy. In the recent war Brian Thomas (1944) applied the principle in a modified form, with a spring-wire elevator applied to a dorsal metal plate upon the forearm and wrist (Fig. 5). Mr. A. M. Hendry (1945) has applied the principle of adding springs to appliances

FIG. 10.—A coiled spring toe-raiser for drop-foot, and a similar device reversed and acting as a plantar flexor spring for calf-muscle paralysis.

FIG. 11.—(a) Paralytic scoliosis showing inability to sit without support. (b) The same patient with true spinal support taken from seat. (c) The same appliance in the course of manufacture.

for the replacement of intrinsic muscular activity in ulnar paralysis. In the ulnar splint illustrated (Fig. 9) the whole appliance is converted into one complete spring. The device is simple to make and apply, and has mechanical advantages in action: One advantage of all these appliances is the relative freedom of the palmar aspect for working purposes. A similar idea can be employed in the foot where, instead of an added spring, steel uprights of an ordinary short-leg appliance are converted into springs for the purpose of replacing either the dorsi-extensors or the plantar flexors of the foot (Fig. 10).

The Spine

The purpose to be achieved by a spinal support is essentially the limitation of movement. It is impossible for any appliance to limit all spinal movement. It is impossible to apply any force upon the exterior of the trunk in an ambulant patient so as to effect any material corrective influence upon structural defects. Support, however, for spinal deformity can be given to a considerable extent, as is shown in one case illustrated—a woman suffering from very severe paralytic scoliosis who, with an appliance, has been able to sit unaided with confidence and to manage her household affairs (Fig. 11).

This appliance illustrates the complexities of manufacture, the craftsmanship involved, and the need for close co-operation between craftsman and surgeon. The essential features are a spring steel pelvic band with spring steel uprights, two at the back and one at each side, the side struts supporting crutches for the axillae. These are joined by padded shoulder straps across the front of each shoulder to the back of the central posterior uprights. Pressure upon the pelvis is distributed through curved mild steel bands moulded above the iliac crests, and with downward extensions at the side of each hip to the seat. The support is strengthened by a moulded sheet of duralumin fitting into the concavity beneath the right ribs. Although such an appliance is not suitable for mass production, great benefit would accrue from standardization of some of its parts—e.g., in the provision of the special screws which are used and which, under present conditions, have to be made individually by hand on a power-driven lathe.

A simpler type of spinal "support," which is merely a brace to limit movement and assist muscular action, is the modified Taylor support made of leather-covered spring steel (Fig. 12). The advantages of this support are: simplicity of manufacture and convenience; the close relation of its uprights to the posterior surface of the spine, which controls antero-posterior movement; the firm hold at its base through the almost encircling steel band round the truss line; and the use of a suprapubic abdominal pad. Furthermore it is readily adjustable in shape by the use of bending irons. It is useful in the treatment of postural defects and adolescent kyphosis, in the convalescence of cases of tuberculosis of the spine, and in the after-care of spondylitis.

The Knee

In acute stages of arthritis of the knee nothing is better than a well-applied, cellulose-lined, long-leg guarding plaster, which can be split as soon as, on clinical grounds, the condition appears to be subsiding. It is then available as a removable splint for the rest of the programme of rehabilitation. A wedging plaster also provides a convenient method of treating flexion deformity while permitting general activity and ambulation. In the later treatment of arthritis of the knee a variety of appliances are available, all applicable to many other pathological and traumatic conditions—e.g., the Thomas weight-relieving calliper.

There is, however, frequently need for an apparatus which permits flexion. Such appliances would be used more often if they were readily available. Here is a particular field for standardization in the interests of mass production, cheapness, and efficiency. One type of joint is shown (Fig. 13) with a locking device to maintain the appliance rigidly in extension when the patient walks. It requires the highest form of craftsmanship as at present made. Such an appliance often has a particular disadvantage—namely, that when it is flexed to a right-angle for sitting the sharp upper angle of the lower section, upon which the lock depends, causes a sharp upward projection which is liable to tear the patient's clothes. This difficulty has been overcome in the splint illustrated by placing the joint

FIG. 12.—The Taylor spinal brace limiting flexion.

within a circular expansion of iron-work with an eccentric joint, so that the sharp upward angle disappears within the circle when the knee is completely flexed.

This appliance (Fig. 14) is made of hand-forged mild steel, the joint surfaces being case-hardened, so as to minimize the effects of friction. There is no reason why its parts should not be made in the rougher stages by the process of drop-forging from prefabricated dies. A suitable die would be expensive to a degree that few workshops would contemplate. If, however, some measure of uniformity could be decided upon throughout all the regional workshops of the country, perhaps with the aid of a large consumer such as the Ministry of Pensions, then a very important practical solution would be found.

Rest in Bed

Sending a patient to bed is the commonest form of rest used in treatment. As almost universally applied it is unphysiological. Bed treatment is only really properly understood and carried out in the care of the really ill patient. For the chronic sick it is sadly misused. The depression of the chest, the compression of the abdominal viscera, long-standing flexion of the lumbar spine, extension of the knees—these are a few of the common defects of the chronic case allowed to sit up in bed. Improvement in our beds for the chronic sick is much needed, but a good deal can be done to make it physiological by providing suitable support and by giving frequent changes to complete recumbency; by improving abdominal tonus and respiratory excursion; by the metabolic stimulus of fresh air, adequate diet, and a proper fluid intake; and by psychological care and occupation. Thus suitable conditions might be provided for the care of individual joint mechanics and for the associated medical treatment of the disease. The Hippocratic principle that the doctor should "do no harm" should be interpreted widely to include the prevention of such results of decubitus as the not uncommon development of renal calculus in orthopaedic patients. In applying physiological principles to the treatment of patients in bed we see the commonest illustration of the principle of physiological rest.

Materials

The work of appliance manufacture is at present hampered by shortage of certain materials, particularly in the grades required. A hope for the future is that recent metallurgical and engineering developments and new plastics will help to solve many of our problems. Of the metals used for splint framework, ferrous compounds are still the commonest, and wrought iron and steel are usual. Steel preponderates, and there are many different qualities for our purposes, ranging from tough malleability to rigid hardness, from mild steel to spring steel.

There seems to be some misunderstanding of the use of iron and steel in splint construction and this appears to have originated with the work of H. O. Thomas. The conditions of manufacture of his day justified his view-point. Mild steel, made possible by the Bessemer process, was not available until the end of Thomas's life. What he wanted was a metal frame with malleability and just sufficient rigidity to maintain the position but not interfere with the surgeon's ability to mould it with bending irons. Wrought iron was the only suitable material—steel as then known (1876–1891) was far too hard and rigid. This does not apply to-day, and yet there are those who advocate

FIG. 13.—The jointed knee calliper.

the use of wrought iron, strangely, for the purpose of its supposed "rigid, unyielding" nature and "not of steel, which would alter in shape under pressure" (McMurray, 1937).

Experimentally it can easily be shown that a mild steel rod, of equal calibre to one of wrought iron, has sufficient malleability and is far superior in rigidity. This may seem a small point, yet the recent war has shown that surgical appliances

FIG. 14.—Jointed calliper locking device. (a) The rough hand forgings. (b) The finished joint locked. (c) Semi-flexed, showing the locking spike disappearing within the circle. (d) In further flexion; complete disappearance of spike. Note eccentric movement which permits this and provides easing of pressure upon the calf band in flexion.

have to be made on occasion by people previously inexpert and who should be guided in the use of the most readily available materials if these are superior to those less easily obtained.

Lightness is a consideration of importance, and the use of duralumin has been advocated. Unfortunately, to provide adequate strength it must be relatively bulky, and it will not stand up to friction. Consequently in jointed appliances the moving surfaces must be faced with hard steel. The result is that appliances thus made are scarcely, if at all, lighter than those carefully forged from mild steel. Processes not yet fully explored are the use of tubular metals and electric welding.

Covering materials provide a difficulty at present owing to the scarcity of supply, particularly of leather. Here in any case improvements are needed in the use of materials which can be moulded upon curved apparatus without folds and which at the same time will be non-irritant to the skin. Perspex and polyvinyl chloride offer possibilities which are beginning to be used (MacGowan, 1943). A noteworthy example is in the work at the Royal National Orthopaedic Hospital at Stanmore reported by Scales and Herschell (1945) and Cholmeley (1946).

Summary and Conclusions

In discussing the present-day change in orientation upon the therapeutic use of rest I have attempted to define our conception of Hilton's term "physiological rest." I have emphasized Thomas's teaching that the surgeon must know how to apply rest physiologically and must also have an intimate knowledge of splint construction and management. In describing a few methods and appliances used in arthritis and nerve lesions I have tried to show some of the difficulties and to indicate the general lines for future research and practical improvement. Apart from improved design and materials, the co-operation of regional surgical workshops (with some measure of standardization) should lead to greater economy and efficiency as well as comfort for the patient. The amount of standardization need not thwart enterprise or originality.

Those of us who consider improvements in design should maintain an attitude of humility. The human form has not altered during the past hundred years. Before the modern advancement of surgical technique many great minds had devoted themselves to this subject. Study of the old masters (Bonnet in particular) reveals how far they had got. Most "new" ideas have been thought of before. Advance chiefly will come in the utilization of new manufacturing processes and new materials.

It is to be hoped that in the museum of the Royal College of Surgeons there may be established a collection, not of "museum pieces" but of well-proved basic surgical appliances with suitable illustrations of their use. Such a section could be of great teaching value.

In any discussion of orthopaedic appliance making acknowledgment should be given to the originality and skill of commercial craftsmen such as Critchley, Ernst, and many others. In addition, I would like to thank my assistants who have helped in the production of this paper; Mr. H. Salz, M.R.C.S., Miss E. L. Burrow, S.R.N., Miss M. Green, Mr. A. Reaney, M.S.R., and above all Mr. F. W. Suler (a "master-craftsman") of the Orthopaedic Workshops, the Princess Elizabeth Orthopaedic Hospital, Exeter.

SOUTH PACIFIC BOARD OF HEALTH

A South Pacific Board of Health, with headquarters in Suva, is established under an agreement which has been signed by the Prime Minister of New Zealand and the Governor of Fiji and High Commissioner for the Western Pacific High Commission. The adoption of a long-range policy of progressive alignment of the medical and health services of Fiji and the Western Pacific High Commission and those of New Zealand and the Dominions' island territories was one of the recommendations made in the Wait-Lambie report on medical services in Fiji. The agreement gives practical effect to this policy, and is the result of negotiations which have been in train since the publication of the Wait-Lambie report early in 1944. It applies to Fiji, the British Solomon Islands Protectorate, the Gilbert and Ellice Islands Colony, Western Samoa, Cook Islands, and the Tokelau Islands. The Board, which will be advisory, will assist the participating administrations in the more effective control of disease and the promotion of health in their territories, and will co-ordinate research and the compilation of statistics on the incidence of disease, with particular reference to the maintenance of standardized quarantine procedure. The Board will also assist in the selection, posting, training, and service conditions of the medical staff.

The agreement contemplates the establishment of a medical centre in Fiji, including a new central medical school and nurses' training school. The secondment of New Zealand nurses to Fiji and other territories will be arranged by the Director, Division of Nursing, New Zealand.

EFFECT OF CERTAIN SOCIAL CONDITIONS ON THE HEALTH OF SCHOOL- CHILDREN

BY

E. R. BRANSBY, Ph.D.

J. L. BURN, M.D., D.Hy., D.P.H.

H. E. MAGEE, M.B., D.Sc.

AND

the late D. M. MacKECKNIE, M.B., D.P.H.

The school-children from Salford included in the vitamin-feeding test in 1943-4, already reported (Bransby *et al.*, 1946), numbered 891. Data covering a wider field and involving a larger number of children were, however, obtained; these were found on examination to be of some interest, being concerned with the relationship between home, family, and economic conditions on the one hand and the rate of growth, certain medical and dental conditions, and school attendance on the other. Involved in this analysis were 2,945 children, 5 to 14 years old, attending 23 elementary schools in Salford, and 82 boys evacuated from Salford to Whiteacre camp school, in Lancashire. They were weighed, measured, and medically examined early in 1943 and again one year later. The weighings, measurements, and medical and dental examinations were carried out in the same way as for the vitamin-feeding test. In addition, information obtained from data collected in Stoke-on-Trent, where the vitamin-feeding test was also carried out, relating absence from school with certain social conditions, is also included. It was the intention to present as full a set of results for Stoke as for Salford, but unfortunately the bulk of the Stoke results were destroyed by accident in the wartime drive for salvage.

Social Conditions and Absence from School

The social matters inquired into were home and economic conditions—each of which was graded good, fair, or bad—the number of children in the family, and absence from school and the reasons for it. Classification of the home conditions was made by individual teachers who knew the children well. In Salford there are few schools with a mixed population of high and low income groups, so the grading into economic groups was a fairly easy matter for the teachers. A sample check of the gradings was made by experienced health visitors, and it was found that their independent judgment corresponded well in the main with that of the teachers.

Clinical and Dental Examinations

The clinical conditions recorded were those which might in some way be affected by the general state of nutrition or specific vitamin deficiencies. The examination consequently was not a complete medical examination covering every aspect of health. The clinical examination paid attention to: state of nutrition (good, fair, or poor), round shoulders, pot-belly, lordosis, winged scapula, knock-knees, bow-legs, scoliosis, deformed chest, physique, obesity, chest rales and cough, ear discharge, goitre, angular stomatitis, cheilosis, pityriasis sicca, pallor of mucous membrane, styes, blepharitis, simple conjunctivitis, phlyctenular conjunctivitis, circumcorneal infection, transverse ridging of nails, nails bitten, brittle nails, coarse and dry hair, impetigo, boils, chilblains, other sepsis, seborrhoea, follicular keratosis, and dryness of the skin. At each examination the conditions were graded 0, 1, 2, or 3, according to their presence and severity.

The dental conditions taken into account were: general tone of the gums and the presence of gingivitis, haemorrhage, tartar, mottling, and caries. The extent of mottling, haemorrhage, tartar, and caries was graded 0, 1, 2, and 3, and gingivitis 0, 1, 2, 3, and 4, in the manner of King, Francklyn, and Allen (1944). The general tone was graded "firm" or "flaccid." All the teeth present in the mouth were examined and graded individually for caries and mottling, and the average caries and mottling per tooth present were calculated. The

examination for general tone of the gums, gingivitis, haemorrhage, and tartar was limited to the regions $\frac{21112}{21112}$, each of these teeth being examined and graded individually.

For the clinical conditions the data of the boys and girls were analysed together; for the dental conditions the data were analysed for boys and girls separately in the age ranges 5-7, 8-10, and 11-13 years.

The average incidence of the above clinical and dental conditions was calculated in children grouped according to the number of children in the families to which they belonged, home conditions, economic conditions, and nutritional grade. Two criteria were used to ascertain if the social circumstances and nutritional classification had any effect on the incidence of the clinical and dental conditions—the trend and consistency of the results, and formal tests of significance of the difference between the best and the worst groups of each of the three social classifications.

Results

To avoid the presentation of a large number of tables a statement of results is here given.

Clinical and Dental Conditions

The incidence of the following clinical and dental conditions increased with worsening social conditions; the figures in parentheses show the extent to which the incidence of the condition among children in bad home or economic conditions or belonging to large families exceeded the incidence among children in good home or economic conditions or belonging to small families. Ranges are given for the figures (in parentheses) because they relate to the three factors, home and economic conditions and number of children in the family, and also breakdowns, according to sex and age. The percentages for all these breakdowns fall, for each of the clinical conditions mentioned, within the ranges given: impetigo (40-60%), sepsis (56-276%), angular stomatitis (36-128%), pityriasis sicca (14-28%), coarse and dry hair (50-400%), dryness of the skin (20-64%), round shoulders (4-71%), deformed chest (37-156%), tartar (75-167%), gingivitis (6-287%), and general conditions of the gums (0-250%). The incidence of caries increased among boys (11-22%). The gradings of nutrition and physique also worsened with decline in social conditions. The incidence of transverse ridging of the nails, which was at one time suggested as a criterion of poor nutrition, decreased with worsening social conditions. For the other particulars there was no discernible variation with social conditions.

Growth

Table I shows the number of children in the various sex, age, and social groups. The heights and weights of children of corresponding ages in good economic conditions, good home conditions, and belonging to families with one or two children were practically the same, and conform to those given in Table II. In Table III, for boys and girls of the age groups 5-7 years, 8-10 years, and 11 and more years, are given the differences in height and weight between those in (1) good and bad home conditions, (2) good and bad economic conditions, and (3) belonging to families with one and two children and families with six or more children.

TABLE I.—Number of Children in Various Sex, Age, and Social Classes

Age (years):	Boys			Girls		
	5-7	8-10	11+	5-7	8-10	11+
Home conditions:						
Good	189	315	193	184	250	246
Fair	179	346	248	185	265	155
Poor	45	29	17	35	44	20
Economic conditions:						
Good	124	157	158	105	142	177
Fair	170	362	214	185	262	158
Poor	119	171	86	116	152	87
Children in family:						
1, 2	207	307	214	191	231	183
3, 4, 5	173	293	187	179	246	189
6 or more	33	90	57	35	78	52

The heights and weights of children in bad economic or home conditions or belonging to large families were consistently less than those of children in good home or economic conditions or belonging to small families. Thus children in good home conditions were 1.7-2.6 in. (4.32-6.60 cm.) taller and 2.0-9.3 lb. (0.91-4.22 kg.) heavier than children living in bad home conditions, children in good economic circumstances were 0.6-1.4 in. (1.52-3.55 cm.) taller

TABLE II.—Approximate Height and Weight of Children with Good Home or Economic Conditions or Belonging to Small Families

Age (years):	Boys			Girls		
	5-7	8-10	11+	5-7	8-10	11+
Height (in.) ..	45.4 (115.3)*	50.6 (128.4)	55.2 (140.2)	45.3 (115.0)	50.1 (127.2)	55.8 (141.7)
Weight (lb.) ..	46.9 (21.27)	59.0 (26.77)	74.8 (33.93)	45.7 (20.73)	57.2 (25.95)	76.3 (34.61)

* The figures in parentheses in Tables II-IV represent the metric equivalent—height in centimetres, weight in kilogrammes.

TABLE III.—Effect of Social Conditions on Initial Height and Weight

Age (years):	Boys			Girls		
	5-7	8-10	11+	5-7	8-10	11+
Height:						
H.C. good minus bad (in.) ..	2.5 (6.35)	1.7 (4.32)	2.6 (6.60)	2.3 (5.84)	1.7 (4.32)	2.3 (5.84)
E.C. good minus bad (in.) ..	0.9 (2.29)	0.6 (1.52)	0.9 (2.29)	1.1 (2.79)	0.8 (2.03)	1.4 (3.55)
No. of children: 1, 2 minus 6+	1.8 (4.57)	0.8 (2.03)	1.0 (2.54)	1.4 (3.55)	1.1 (2.79)	0.6 (1.52)
Weight:						
H.C. good minus bad (lb.) ..	3.8 (1.72)	3.8 (1.72)	9.0 (4.08)	3.4 (1.54)	2.0 (0.91)	9.3 (4.22)
E.C. good minus bad (lb.) ..	1.6 (0.72)	0.5 (0.23)	2.5 (1.12)	0.5 (0.23)	2.3 (1.04)	5.6 (2.54)
No. of children: 1, 2 minus 6+	3.6 (1.63)	2.0 (0.91)	6.6 (2.99)	1.3 (0.59)	2.4 (1.09)	2.0 (0.91)

H.C. = Home conditions. E.C. = Economic conditions.

and 0.5-5.6 lb. (0.23-2.54 kg.) heavier than those in poor economic circumstances, and children in small families were 0.6-1.8 in. (1.52-4.57 cm.) taller and 1.3-6.6 lb. (0.59-2.99 kg.) heavier than those belonging to large families.

TABLE IV.—Effect of Social Conditions on Height and Weight During a Year

Age (years):	Boys			Girls		
	5-7	8-10	11+	5-7	8-10	11+
Height increases:						
H.C. good minus bad (in.) ..	-0.21 (-0.53)	-0.01 (-0.025)	0.18 (0.46)	-0.21 (-0.53)	0.05 (0.125)	0.23 (0.58)
E.C. good minus bad (in.) ..	0.22 (0.56)	0.12 (0.30)	0.69 (1.75)	0.20 (0.51)	0.25 (0.64)	0.48 (1.22)
Weight increases:						
H.C. good minus bad (lb.) ..	0.47 (0.21)	-0.56 (-0.25)	2.95 (1.36)	0.97 (0.44)	0.60 (0.27)	4.33 (1.96)
E.C. good minus bad (lb.) ..	-0.13 (-0.06)	-0.70 (-0.32)	1.83 (0.83)	1.02 (0.46)	-0.82 (-0.37)	2.88 (1.31)

H.C. = Home conditions. E.C. = Economic conditions.

Table IV shows the annual height and weight increases of boys and girls aged 5-7 years, 8-10 years, and 11 or more years, grouped according to home conditions and economic conditions. In good economic conditions the growth of children was better in all six age groups by 0.12-0.69 in. (0.30-1.75 cm.) than that of children in bad economic conditions, but there was no consistent difference between weight increases, except for boys and girls of 11 years in good economic circumstances, whose increase was 1.83-2.88 lb. (0.83-1.31 kg.) better than for similar children in poor economic circumstances. On the other hand, the children living in good home conditions did not grow in height any better than those in poor home conditions, but the weight increase was better in five out of the six groups by 0.47-4.33 lb. (0.21-1.96 kg.).

TABLE VI.—Absenteeism, Days per Child, due to Various Causes according to Sex and Age

Age (years):	Stoke-on-Trent						Salford

Absence from School

All practicable steps were taken to ensure that the reasons absence from school were accurately recorded. Both in Stoke and in Salford the services of the health visitors or school nurses were used in checking the reasons given for absence. The absences were grouped into the various categories listed in Tables V and VI, collaborators in Stoke and Salford, and this may have caused some lack of uniformity and account in part for the differences found between the two areas. Consequently comparison between the results for these towns can only be made with caution.

Table V shows, for boys and girls living at home in Stoke and Salford, the number of days' absence from school for various causes and the percentage of the total absenteeism due to each cause, and Table VI shows the absenteeism of children grouped according to sex and age.

TABLE V.—Absenteeism, Days per Child, due to Various Causes

Cause of Absence	Stoke-on-Trent		Salford		Cam Scho
	Boys	Girls	Boys	Girls	
Number ..	510	410	1,561	1,384	
Respiratory ..	5.2 (21%)	7.4 (26%)	12.0 (30%)	13.9 (31%)	2.1
Skin ..	2.4 (9%)	2.1 (7%)	2.2 (6%)	2.0 (5%)	1.1
E.N.T. ..	1.7 (7%)	2.6 (9%)	2.6 (7%)	4.1 (9%)	2.1
Gastro-intestinal ..	1.1 (4%)	1.4 (5%)	2.5 (7%)	2.9 (7%)	1.1
Eyes ..	0 (0%)	0.2 (1%)	0.1 (0%)	0.2 (0%)	0
Infections ..	3.1 (12%)	2.2 (8%)	3.7 (9%)	3.7 (8%)	0
Unspecified ..	4.7 (18%)	7.3 (26%)	2.1 (5%)	3.2 (7%)	1.1
Injuries ..	1.1 (4%)	0.9 (3%)	2.0 (5%)	1.5 (3%)	0
No illness ..	6.4 (25%)	4.1 (15%)	12.2 (31%)	12.7 (30%)	13.4
Total ..	25.7	28.2	39.4	44.2	23.6

Table V reveals that in Salford respiratory conditions and causes other than illness each accounted for about 30% of the total absenteeism, the other 40% being due to the remaining seven causes. In Stoke, absenteeism due to respiratory conditions was 21.26% and causes other than illness 15.25%. In Salford, absence due to unspecified illness amounted to 18.26% compared with 5.7%. The discrepancy may have been due to the grouping of the various illnesses into different categories in the two localities. Total absenteeism comprised about 12% of the possible school attendance in Stoke and 18% in Salford.

Sex and Age

Girls had somewhat more absenteeism—about 10% in Stoke and 15% in Salford—than did boys. The incidence both of respiratory and of E.N.T. conditions was consistently greater for girls than for boys.

Absenteeism was greater among young children than among older ones. Thus for children aged 5-7 years, compared with those aged 11 or more, absence was about 5 days (15%) greater in Salford and about 20 days (90%) greater in Stoke. Absence due to infectious disease was considerably greater among young than among older children, and the younger had a somewhat higher incidence of respiratory complaints. In Stoke the incidence of unspecified illness was also much greater among young than among older children. Older children in Salford were somewhat more often absent owing to causes other than illness—about 35%, compared with about 25% of total absence for younger children—but the difference was not so marked for Stoke.

Social and Economic Conditions

In Salford the number of children in the families had no effect on absenteeism, but among children with bad home conditions absenteeism was 30 to 40% greater than among those with good home conditions, owing to some extent to a greater incidence of skin conditions, but mostly to absenteeism from causes other than

iness. Among children in good home conditions 25% of the total absenteeism was due to causes other than illness; among children in poor home conditions the proportion was 36 to 41%.

Nutrition

Children graded as of poor nutrition in Salford had about 15% more total absenteeism and absenteeism due to illness than had children of good nutrition, while in Stoke the differences between children with good and those with poor nutrition was 30 to 40%. Absenteeism among boys living in Whiteacre camp school was considerably less than that of boys living at home at Salford—total absenteeism being 23.6 days, compared with about 37 days—and that due to illness 9.4 days, compared with about 24 days for boys aged 14 years in the two localities. The relatively high absenteeism through causes other than illness was due to the fact that the children lived in the camp school and occasionally visited relatives and friends. The difference in the sickness rate of the Salford children from that of the camp school children was due almost entirely to absence from respiratory conditions; this averaged about 12 days for the Salford boys and 2 days for the Whiteacre camp school boys.

Discussion

Analysis shows that there is a relationship between on the one hand social conditions as represented by home and economic conditions and the number of children in the family, and on the other hand the health of the Salford children as represented by the somewhat limited range of conditions noted at the clinical examination and by the growth data—the poorer the social conditions the worse the health levels. Yudkin (1944), in a study of the nutritional condition of children in Cambridge, found that children in a school in a fairly poor district, compared with those in a school in a comparatively well-to-do district, were on the average 0.8 in. (2.03 cm.) shorter, and 6 lb. (1.18 kg.) lighter, and had 2% less haemoglobin and a grip 1.25 kg. weaker. The absenteeism data suggest that social conditions did not affect absence from school due to illness, although with worsening home conditions there was a substantial increase in absence due to causes other than illness. It is important, however, to note (a) that absenteeism among children graded "poor nutrition" was considerably greater, both in Stoke and in Salford, than among those graded "good nutrition"; and (b) that there was a general lowering of the nutritional grading with worsening social conditions. Further, the average number of days' absence through illness among the camp school children was 9.4, compared with about 24 for boys living in Salford and about 14 for boys living in Stoke. It is also noteworthy that total absenteeism in Salford was about 65% greater than in Stoke, and that due to illness about 3% greater. The amount of absence due to illness, particularly respiratory conditions, appears to vary considerably from locality to locality, and the point arises as to how much of this is due to bad environment. It is not suggested that figures for the camp school children, extending as they do over one year only, represent the long-term morbidity rate of children living under such conditions, but the difference between them and the figures for Stoke and Salford at least suggests some association between morbidity of children and their living conditions.

Summary

Data of 2,945 children aged 5-14 years attending day schools at Salford, and of 82 children living in a residential camp school, were analysed to show the relation between home, family, and economic conditions on the one hand and rate of growth, state of health, and school attendance on the other. Information obtained from data collected in Stoke-on-Trent relating absence from school with certain social conditions is also included.

An increase in the number of children in the family and worsening home and economic conditions were associated with a reduced rate of growth and state of health. Absence from school was not related to family size, but increased with worsening home conditions and state of nutrition. There was greater absenteeism among young boys than among older children and among girls than boys.

Absence from school from all causes and from illness was greater at Salford than in Stoke-on-Trent, and absence in both localities was greater than that in the residential camp school, which suggests that environmental factors were at least in part responsible for absence from school and for child morbidity.

We wish to express our thanks to the parents of the children participating in the test and to the staffs of the Education and Health Departments of Stoke-on-Trent and Salford for collecting the experimental data. Thanks are also due to Mr. S. H. Quayle,

Controller, Statistical Branch, Customs and Excise, for analysis of the data on Hollerith machines, and to Dr. H. O. Hartley, of the Scientific Computing Service, for computations. Particularly we wish to thank Dr. V. C. Veitch for his assistance after the retirement of the late Dr. D. M. MacKecknie.

THE EVALUATION OF BARRIER CREAMS

BY

C. G. A. SADLER, M.R.C.S., L.R.C.P.

AND

R. H. MARRIOTT, D.Sc., F.R.I.C.

The ability of barrier creams to prevent deleterious substances reaching the skin of operatives has been amply proved in practice, and it can be asserted that the so-called "invisible glove" produced when these preparations are properly applied has done much to limit the incidence of dermatitis. Much has been written and spoken about the principles which must be obeyed if a satisfactory barrier cream is to be arrived at. Some formulators have included substances with the idea of increasing the scope of these preparations, but sometimes these additions are based on premises which are either hypothetical or, at the best, ill-founded. Others have attempted to medicate them, but whether in doing so the product has an added value as a protective cream is quite another matter. Although it may be that in theory a universal elixir could be made, the experience of those whose job it is to produce an article of real worth leads to the sound belief that it is always better to keep the product as simple as possible and to concentrate on making one which is as perfect as it can be to fulfil the essential requirements.

Barrier creams are expected to form a barrier against deleterious substances. That is the essence. They are not supposed to be cure-alls for any local erythema. They must be easy to apply and they must leave a coherent film which is impervious to extraneous substances. But they must be comfortable in wear. They should not produce a feeling in the mind of the user that the part anointed is encased; the invisible glove should preferably be imperceptible. Neither should the film be tacky or greasy so that it can contaminate any article which has to be handled; it is very important that articles handled should not slip from the grasp. Naturally, too, the film must be flexible so that it does not crack or form fissures. A case can be made out for the inclusion of substances which can neutralize or render inert specific irritants, but although in some instances this is advisable, and indeed desirable, the efficiency of a film of barrier cream to do this cannot be other than of a low order. If it is remembered that a proper film is only about 10 to 20 μ in thickness it will quickly be appreciated that the amount of neutralizing agent per square centimetre of skin surface is very small. Such additions cannot, therefore, deal with more than traces of the irritant; they are really useful only when the irritant is highly toxic even when present in minute quantities. Finally, in view of the general reluctance of people to take prophylactic measures, the interest of the user has to be titillated, and this can be done in no small measure by making the cream pleasant in appearance and texture. A minute trace of an odoriferous principle is a useful addition provided that it does not lead to the scenting or perfuming of the product which is to be handled.

Owing to the diversity of industrial processes and products it is not possible to make one cream which can give protection against everything. Neither is it a practical proposition to make individual creams for every specific hazard. The compromise is to classify the known deleterious substances into groups. Investigation suggests that four types of barrier cream are necessary, and the four classes of hazard are: (1) irritant dusts; (2) aqueous materials; (3) solvents and oils; (4) aqueous and oil-containing substances. Barrier creams which will give protection against the first class must produce a coherent film which adheres well to the skin and which will prevent the dust

penetrating or gaining access into the hair follicles and sweat ducts. The film must be non-tacky and non-greasy. Barrier films which are to give protection against the second class must produce a flexible water-repellent and water-resistant film, free from tackiness and greasiness. Protection against solvents and oils—class 3—can be obtained only if the film is composed of oil-insoluble materials. Provided this is accomplished and the requirements as to adherence, flexibility, and non-tackiness are fulfilled, a satisfactory protective barrier can be produced. The fourth class is probably the one which raises most difficulties, since the two main components, water and oil, are diametrically opposed in their properties, and their simultaneous presence makes the formulation of an efficient barrier cream difficult. However, by a careful compromise creams can be made which, when allowed to dry out into a film, have a reasonably high resistance to both water and oil.

The measurement of the efficiency with which a barrier cream prevents deleterious substances from producing dermatological rashes or oedemas can be carried out in a number of ways. The most logical one is the clinical experiment; but, with this form of appraisal, reliable estimations of value can be obtained only as a result of the statistical analysis of a large population. The inherent difficulties in mass clinical trials are too numerous and well known to be described here, although it is to be borne in mind that such tests are, in the long run, the final arbiters of efficiency.

The quick assessment of value demands some form of laboratory procedure of a somewhat empirical nature. When the conditions under which the film of barrier cream has to fulfil its functions are considered, it is immediately obvious that to devise an apparatus in which all these conditions—such as flexibility, resistance to friction, adherence to a non-rigid base which is subject to varying degrees of moisture on one side owing to perspiration, etc.—are imposed becomes wellnigh impossible. Even if such an apparatus could be designed it is most unlikely that answers free from ambiguity would be produced. It is really far better to use simple tests and simple apparatus which, while functioning in quite an artificial way, are more likely to yield consistent results. Provided that the artificiality is realized and that no attempt is made to read into the answers anything more than the test professes to do, then such means of evaluating barrier creams are justified and of considerable value.

Qualitative Tests

One of the means of testing consists in spreading the barrier cream on a suitable glass surface and allowing it to dry into a film. This film is then carefully taken off the glass and immersed in the liquid against which it is supposed to be a barrier. By comparing the times taken for the film to disintegrate the comparative efficiency of creams can be assessed. This method was advocated in a "Memorandum on the Prevention of Industrial Dermatitis," with special reference to the use of barrier substances, Form 330, December, 1942, issued by the Factory Department of the Ministry of Labour and National Service. It is not very easy, however, in all cases to produce films which can be peeled off a sheet of glass, and in the experiments which have been carried out the film was allowed to remain on the glass while being treated with various reagents.

This method has been used for a number of commercial creams of different manufacture. In order to identify the creams they have been numbered as follows:

- | | |
|--|--------------------|
| 1. Barrier against fine dusts and for handling dry materials | } Made by firm "A" |
| 2. Barrier against aqueous liquids | |
| 3. Barrier against oils and solvents | |
| 4. Barrier against both oils and water | |
| 5. Barrier against non-aqueous material | } Made by firm "B" |
| 6. Barrier against aqueous solutions | |
| 7. Barrier against non-aqueous material | } Made by firm "C" |
| 8. Barrier against aqueous solutions | |

Under the test the films made from Nos. 3, 5, and 7 rapidly disintegrate, especially if the test liquid be either acid or alkaline. No. 1, although not claimed as water-resisting, is definitely better than either 6 or 7, while No. 4 is remarkably resistant to solutions of acid. No. 6, which is claimed to be

water-repellent, breaks down quickly when subjected to the test. It is to be noted that when a film is not stable to the solvent becomes opalescent in a short time; the onset of the opalescence is a fairly good indication that the film is absorbing the liquid and will soon disintegrate. Carried out under standard conditions of time and temperature, this test is very useful, but the results can easily be vitiated if care is not taken to make the films as nearly as possible all of the same thickness.

Another qualitative method is merely to shake up some of the cream with aqueous solutions. If the cream is truly water repellent it will not disperse in the aqueous solution. If it is partially resistant to water it will not fully disperse, whereas if its resistance to water is poor it will wholly disperse. By this means differentiations can be made between the various creams and it has been found that creams Nos. 5 and 7 do not stir up at all well under this treatment. On the other hand, No. 1 cannot be dispersed in the aqueous solutions, while both No. 2 and No. 4 show a resistance to dispersion which indicates that they possess resistance to water. This method can show quite considerable differences between acid and alkaline solutions. In general the acid solutions, as is perhaps to be expected, prevent dispersion of the creams, and all the creams, especially Nos. 2 and 6, have some resistance to acids. In respect to alkaline solutions the only satisfactory cream is barrier cream No. 2. This method cannot be used for testing the resistance to non-aqueous solvents, since all the oil-resistant creams are obverse emulsions—i.e., water is the outside phase and the cream therefore cannot mix with oils.

Another method of investigating the resistance of the film to water followed the method described by Grant for measuring the degree of water-resistance of paper. The method consists in sprinkling the surface of paper with a small amount of icing sugar to which has been added 0.5% of "rhodamin 6G". The paper is floated on the surface of some distilled water at the surface examined under ultra-violet light. As soon as the dyestuff becomes wetted it shows a bright fluorescence, and the time taken for this to occur can be noted. The method does not, however, give a very sharply defined end-point, the fluorescence growing in intensity rather than appearing suddenly. At the same time the results are also subject to the variations in the thickness of the film; but if a rough allowance be made for this by repeating the observations several times, the creams can be differentiated one from another. In Table I figures are given for average results of a number of barrier creams, together with the time taken for the moisture to penetrate the untreated paper. In these experiments the writing-paper or typing-paper was used for the membrane and not filter-paper.

TABLE I.—Rate of Penetration of Water through Films of Barrier Cream, using the Fluorescence of a Dyestuff in the U.V. as a Measure of Penetration

Cream Used	Time Taken for Fluorescence to Appear
Blank: paper only	14 seconds
Barrier cream No. 1	21 "
" " No. 2	121 "
" " No. 3	19 "
" " No. 4	75 "
" " No. 7	17 "
" " No. 8	25 "

It will be noticed that this method differentiates between No. 2 and No. 3 creams, which, when tested by direct measurement of the volume of water penetrating a direct film of the cream (see Table IV), indicated that No. 3 had a higher resistance to penetration. It should be borne in mind that the ultra-violet light will detect extremely small amounts of moisture on the upper surface of the film, the least trace causing solution of a minute quantity of the dyestuff, which is the strongly fluorescent. The test certainly seems to place the creams in the order which would be expected.

It is also possible to measure the resistance of the barrier film in a rough quantitative way by allowing a drop of a solution of dye to fall on to the surface of a piece of typing-paper which had previously been coated with the cream and allowed to dry. Ordinary red ink was used as the dye solution, and the drop was allowed to remain on the surface for exactly for

nutes, when it was dried off by means of a piece of filter-paper. Drops of the ink were placed on typing-paper and allowed to remain on for varying lengths of time, ranging from 2 to 4 minutes, when they were blotted off. The series of its showing on the reverse side of the paper was used as the standard to compare against the colour obtained on the reverse of the paper when barrier creams had been used. In this way it was possible to assess the resistance of the film of barrier cream. The results are given in Table II. In expressing the results the permeability of the untreated paper has been taken as 100, and the depth of shade produced when the barrier cream is present is expressed as a percentage of this. Thus a figure indicates low permeability.

TABLE II.—Percentage Permeability of Films of Barrier Cream as Determined by the Penetration of a Solution of Eosin

Cream	Percentage Permeability
No. 1	85
No. 2	30
No. 3	80
No. 4	10
No. 5	70
No. 6	10
No. 7	70
No. 8	20

It is to be noted that when this test is carried out some creams cause the drop of ink to spread out a little, whilst in others the size of the drop does not alter in the four minutes for the test. Creams Nos. 5 and 7 cause the spot to read considerably. This is due to the low contact angle between the ink and the film, and it is suggested that this may be a defect in the creams when it occurs.

Quantitative Tests : pH Value

There is abundant evidence that creams with a high degree of alkalinity can, of themselves, cause irritation of the skin of many people. The Medical Branch of the Factory Department of the Ministry of Labour is well aware of this. It must be realized, however, that to define the pH value of a cream is no means simple, as obviously it will depend on the state of dryness of the cream when the determination is made. To attempt to determine the pH value of a pasty material is not easy, and accordingly it was decided to dilute the creams with an equal quantity of distilled water before making the determination.

In a comparatively rough way the pH value of creams can be determined by direct spotting with an indicator, but the results obtained must always be treated with some little reserve owing to the error of the indicator itself. All the creams, except Nos. 2 and 6, have been examined by diluting with an equal part by weight of distilled water and measuring the pH value of the mixture by means of a glass electrode. Table III gives the pH values for a number of creams as determined by this method.

TABLE III.—pH Value of Barrier Creams diluted 50/50 (Glass Electrode)

Cream	pH
No. 1	7.7
No. 3	8.0
No. 4	8.0
No. 5	9.3
No. 7	9.8
No. 8	9.1

NOTE.—It is impossible, of course, to determine the pH value of barrier cream No. 2, which is a reverse emulsion. The pH value of the dispersed water, however, is approximately 7.0. In the same way it was not possible to determine the pH value of barrier cream No. 6, as it does not mix with water.

It is to be noticed that Nos. 5, 7, and 8 have very high pH values and must be condemned on this ground.

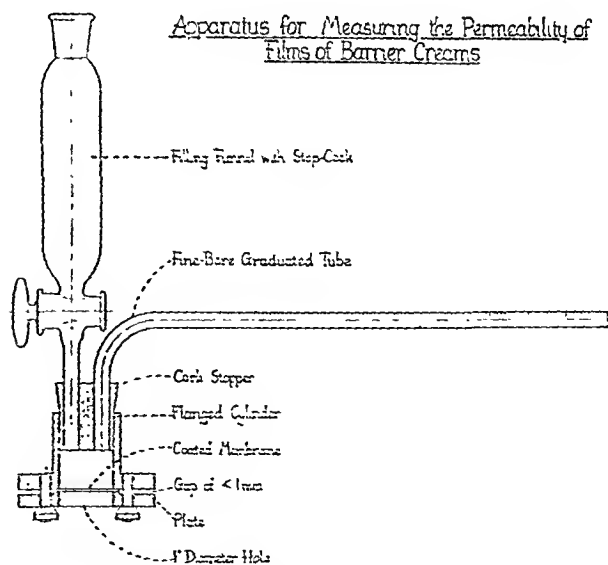

Permeability Tests

Although the above methods of examination give results which enable reasonable comparisons to be made, it was felt that something of a more practical character was desirable. For the first experiments it was considered that, ideally, thin horizontal "splits" of sheepskin—the form known commer-

cially as flywing skiver—would form the best membrane on which to spread the creams, but owing to the close texture of the skin itself, and the fact that when it became wetted with water the skin fibres themselves swelled so that the membrane became less and less permeable to moisture, the time taken to carry out a test was so long that this material had to be abandoned. After experimenting with other materials, such as "cellophane," writing-paper, and typing-paper, the conclusion was reached that for laboratory work it was better to have a very permeable material, so that the resistance produced by the presence of a film of the barrier cream made a large alteration in the rate at which the liquid could penetrate the membrane itself. Filter-paper was found to be suitable, especially, the type known as "Whatman No. 5," which, although a little rough on the surface, was sufficiently hard and rigid not to break down when wetted or during the application of the cream.

The method adopted originally consisted in applying a small quantity of the cream by means of the finger to the filter-paper, which had previously been weighed. It was found that one application did not usually produce a continuous film, and later two or three layers were rubbed on, the film being dried between each application. After drying, the disks of filter-paper were weighed, the difference between the dried weight of the filter and the dried weight of the filter plus cream being taken as a measurement of the thickness of the actual film, the area of course being constant. A further improvement of the method was to stain the filter-paper with red dye, "rhodamin," and then to dry before applying the barrier creams. By this means it was possible to see more clearly where the film was thinnest, so that in the second or third applications these parts could receive a little more of the cream than the other portions. This led to a substantial improvement, although perfection was not achieved.

The films were then placed in an apparatus which consists of a plate and a flanged cylinder of phosphor bronze, machined so that the surfaces fit perfectly together (see Diagram). In the centre of the plate there is a hole of 1 in. (2.5 cm.) diameter—i.e., equal to that of the bore of the flanged cylinder—and the two parts are fastened together by means of six thumbscrews, the coated membrane being thus securely held and forming the septum through which the experimental liquid is to pass. The cylinder is closed by means of a tight-fitting

cork through which two orifices are bored. The apparatus is filled by means of a small separating funnel which passes through one of the orifices, and water or other liquid is admitted until it runs out of the graduated tube, which passes through the second hole in the cork. As soon as the apparatus is full the cock of the separating funnel is turned off and the passage of water through the membrane is measured by observing the reading of the meniscus in the graduated tube at different time

intervals. The graduated tube is calibrated in hundredths of a millilitre. The membrane is placed in the apparatus with the film side uppermost. The machined surfaces are made so that when the membrane is secured the metal surfaces beyond the area of the coated membrane are at least 1 mm. apart; otherwise, when the film is breaking down, end-effects come into play through capillary action in between the two phosphor-bronze surfaces that tend to vitiate the results.

Experiments to investigate the effect of the thickness of the film did not lead to any really satisfactory results, although, in general, the rate of penetration became less the thicker the film. This lack of uniformity in the experimental figures has been attributed to the lack of evenness of the film. Various attempts have been made to overcome this difficulty, and apparatus has been made with sintered glass in place of filter-paper, the sintered glass being fused into a tube and ground off dead level with the end of the tube. This tube was placed inside a wider metal tube and the height adjusted so that the surface of the sintered glass was approximately one-fifth of a millimetre below the top surface of the outer metal tube. This space was then filled with cream and wiped level by means of a straight-edge. It was found that the films obtained by this means were quite regular; but, unfortunately, the cream did not always adhere to the sintered glass, and peeling could occur when the disk and film were treated with water. It was obvious that sintered glass was not an ideal surface, and experiments have now been carried out which suggest that satisfactory films can be spread on filter-paper, using a microtome, in which the filter-paper is dropped into the hole of the microtome to an adjusted depth, the space filled with cream and wiped off with a straight-edge using the top surface of the microtome as a guide. A piece of apparatus on these lines is being made so that filter-papers of suitable size can be coated.

It was found that in order to get figures with any meaning at least six tests had to be made with each sample of cream, rejecting those figures which were violently different from the general run of the other determinations. In calculating the permeability figures an attempt was made to compensate for the variations in the actual amount of cream on the filter. In the absence of accurate data for the relationship between the permeability and the actual thickness of the film, it was assumed that the volume of liquid transmitted was inversely proportional to the weight of the cream per unit area of the filter. It was realized that this relationship was not a straight-line function, but was probably a function to some power of the thickness. Nevertheless, by multiplying the volume of liquid transmitted by the weight of the cream the figures for different films came closer together and did permit some general comparison to be made between the different creams, especially when it is borne in mind that the calculated values contain a not inappreciable error.

The difficulties in obtaining a uniform film have led to the carrying out of a large number of experiments which, in the long run, had to be rejected, but by using tinted paper and applying the cream in three portions a series of figures has been obtained showing the differences between a number of barrier creams, the data being given in Tables IV and V. The method of expressing the results was to take the arithmetic mean of the volume of water or liquid as determined by the reading on the graduated tube for a number of membranes coated with the same cream. The readings were taken at intervals of fifteen minutes, and the amount which penetrated in successive periods of fifteen minutes was divided by fifteen to bring it to the rate per minute; this value was then multiplied by the average weight of the film per standard area. The weight figure was used as an indication of the volume of the film and, although the specific gravity of the creams may vary slightly, no notice was taken of this variation except in the case of barrier cream No. 2, which contains no fillers and which has a specific gravity considerably less than that of the others. The figures of No. 2 are therefore calculated back as though the dried cream has a specific gravity of 1.6, which is approximately the specific gravity of the other creams when dried to a film.

It will be seen from Table IV that of the creams which are designed to resist the penetration of water No. 4 is the most efficient. Next comes No. 2. Nos. 6 and 7 are not satisfactory.

It is interesting to note that No. 3 cream shows a very low water permeability, although it is designed to prevent oil penetrating. The reason for this anomalous behaviour is that it contains hydrophilic colloids which imbibe water without, necessarily, allowing liquid water to pass through. It will be appreciated that this type of cream will give very low figures when used in the apparatus, although it is quite unsuitable:

TABLE IV.—Rate of Penetration of Water through Films of Barrier Creams

Cream	Ml. $\times 10^{-5}$ of Water Transmitted per Minute per Unit of Cream during					
	First 15 min.	Second 15 min.	Third 15 min.	Fourth 15 min.	Fifth 15 min.	Sixth 15 min.
No. 1	310	141	78	104	97	95
No. 2	104	81	79	73	71	56
No. 3	174	96	70	52	40	33
No. 4	200	115	48	34	30	15
No. 5	340	90	59	44	34	31
No. 6	970	770	670	410	334	261
No. 7	310	208	190	190	166	181
No. 8	274	173	142	115	104	81

a protection for the skin against water. Films composed of hydrophilic colloids such as gelatin, etc., will allow water to diffuse but will not easily transmit water in bulk. It is also worthy of note that cream No. 5, which gives such a low permeability to water, is the one which is advocated as protection against oils and non-aqueous materials, whereas cream No. 6, which is recommended as a water-repellent, appears to be the worst of the whole range. Cream No. 4 has only a medium resistance to water. It is probable that the poor results given by creams Nos. 5, 6, 7, and 8 are due to the large amount of soap which is their main constituent and there is no doubt that the film produced when the cream dries can readily be re-emulsified by the addition of water. It would appear that in formulating creams Nos. 1, 2, 3, and efforts have been made to produce an emulsion with the minimum amount of emulsifying agent so that the danger of the dried material being re-emulsified when coming into contact with water would be at a minimum.

In testing creams for their resistance to oil and solvents on white spirit has been used. Other solvents should, of course, be tried if the barrier action is to be assessed for any particular set of works conditions. Only those creams were tested which are claimed to be protectors against oils, and the experimental results are given in Table V.

TABLE V.—Rate of Penetration of White Spirit through Films of Barrier Creams

Cream	Ml. $\times 10^{-5}$ of Oil Transmitted per Minute per Unit of Cream during

With regard to the oil permeability, it will be seen that barrier cream No. 3 is superior to either of Nos. 5 and 7, and especially to No. 5.

Conclusions

The experimental work recorded above indicates that laboratory tests can be used in order to evaluate the quality of the different types of barrier cream which are on the market. In drawing this inference from the experimental work, however, we are aware that the *in vitro* testing cannot simulate, in all details, what actually happens when the barrier creams are applied to the skin and are subjected to the stresses imposed during manual work. At the same time, from the experience which has been gained by the use of some of these creams under actual working conditions, it can be stated that the laboratory tests have been well substantiated and those creams which failed under the laboratory conditions also failed when used in the factory.

It can be recommended, therefore, that medical officers, and those engaged in industrial welfare, can gain a very good indication of the value of the various preparations on the

arket before they go to the extent of introducing them to workers. It is to be borne in mind that it is not logical to y that because a particular preparation stood up to the boratory tests it must, *ipso facto*, be an excellent cream as a rrier against dermatitis-producing substances.

Summary

Means of testing the efficiency of barrier creams have been scribed of both a qualitative and a quantitative character. It s been shown that there are a number of simple tests which can e rough evaluations of the value of these preparations.

Where a more quantitative assessment is desired the apparatus d methods described in the paper are put forward as means ich enable the assessments to be made in a more precise manner. It is to be stressed, however, that the final arbiter of quality must t on the clinical testing of the creams.

AN AID TO THE MEASUREMENT OF VENOUS FILLING IN THE NECK IN CONGESTIVE HEART FAILURE

BY

A. W. D. LEISHMAN, D.M., M.R.C.P.
Honorary Physician, Royal Infirmary, Sheffield

linicians a hundred years ago were aware that the jugular ins became engorged when the heart failed, but the henomenon attracted no special attention. It was left to ewis (1930), of our generation, to point out the practical alue of this sign in diagnosis. It is due to his wise insis- nce that inspection of neck veins now takes its place alongside adiac auscultation as a routine part of clinical examination.

Lewis indicated that a rough but adequate estimate of venous ressure (i.e., pressure within the right auricle) could be made by oting the vertical height of the blood column in the external igular veins above the "zero level" represented by the "angle f Ludwig." The angle does not, of course, correspond anatomically to the vena cava opening which lies behind the ight sternal border at the level of the third interspace, but is convenient for measurement and in practice suitable. Examination of a number of normal subjects confirms Lewis's tatement that venous filling extends to an average height of cm. below the horizontal plane of the angle when the subject s supine, but with increasing inclination of the trunk the zero evel approaches this plane. As patients with congestive failure ill seldom be examined in the recumbent position the error is ikely to be small and the vertical height of the blood column ove the angle can be taken as a true measure of the increased enous pressure.

Absolute measurements of venous blood pressure can be ade, but even the newest and neatest instrument, called by ts designers (Winsor and Burch, 1943) a "phlebomanometer," uffers the inevitable disadvantage that a needle has to be ntroduced into a vein. Measurement of intra-auricular pres- ure by cardiac catheterization will hardly be claimed as a edside manoeuvre even by the greatest enthusiast. The state of the neck veins therefore remains the clinician's principal guide to venous pressure.

It is the usual practice to measure increased venous filling with one horizontal and one vertical ruler; accurate measure- ments by this means, however, demand an unusually skilled eye, and experience shows that two persons attempting the same measurement seldom agree; the record of day-to-day readings in the same patient therefore loses much of its value. On the other hand, if comparable measurements can be made there is much to be learned from serial records, in particular as an index of the response of congestive failure to treatment. For example, in a case where digitalization is achieved by the intravenous route a record of venous pressure over a period of an hour may be most illuminating.

A simple measuring instrument (Fig. 1) which eliminates the personal errors inherent in the ruler method has been designed. It consists of a vertical pillar graduated in centimetres and millimetres, with a pointed rubber-covered base; sliding on the

pillar is a horizontal arm which by means of a rack-and-pinion can be raised or lowered on turning a wheel. The arm, which is accurately maintained at a right-angle to the pillar, bears upon its upper surface a small spirit-level.

To make a measurement (Fig. 2) one hand holds the instru- ment by the knob at the top of the column and the pointed base is placed upon the manubrio-sternal angle; the other hand, by rotating the wheel, raises or lowers the arm until its lower edge is aligned with the level of the top of the blood column in the vein, at the same time maintaining the bubble in the spirit-level at the central mark. The instrument is then lifted and the height of the arm read off the scale on the pillar; this neces- sarily represents the vertical height of the blood column above the sternal angle irrespective of the angle of inclination of the patient.

The actual measurement can be made single-handed in a few moments. There can, however, be no economizing on time spent in identifying the level of venous filling. Lewis himself advised that the neck should be examined in a "thoughtful manner." Experience confirms the soundness of this counsel. A measurement made after a cursory inspection is likely to be entirely false. The pitfalls which may ensnare the careless are many, but once recognized they can be by-passed and measure- ments made with confidence.

Without wishing to stress the difficulties unduly, it may be helpful to indicate briefly the common sources of error. The level to which the veins are filled may be obvious, but in a fat patient or where the veins in their upper course run deeply

FIG. 1.—Diagram of the instrument.

FIG. 2.—The instrument in use.

this is not the case. On the other hand, in a thin subject the veins may be easily visible throughout their course and some difficulty be experienced. Lewis advised that the vein should be obstructed at the base of the neck by light finger-pressure and the level noted to which the blood column fell on release.

This may be helpful, but in my experience the best clue is the level of venous pulsation at the top of the blood column. On close scrutiny this can usually be ascertained. For example, in a case with congestive failure the blood column may appear to end at the posterior border of the sterno-mastoid muscle owing to pressure of the bulging muscle-belly, whereas the level of venous filling is in fact higher, as indicated by the presence of venous pulsation. Individual veins may be full because they are obstructed by muscle pressure at the root of the neck; contracting platysma, on the other hand, will obliterate the vein. Both difficulties are quickly resolved by altering the position of the head and by proper relaxation of the neck. Permanent venous obstruction is most commonly due to thyroid enlargement and, less commonly, to lymph nodes, mediastinal tumours, thrombosis of the vein, etc. Obstructed veins do not pulsate, and show no variation with change in the patient's position; unequal filling of various veins examined is a clear indication of obstruction. Deformities of the thoracic skeleton, such as severe kypho-scoliosis with increased depth of chest, will cause inaccurate measurement if the patient is semi-recumbent; in more erect positions the error becomes progressively less.

With these possible difficulties in mind it is advisable, on the first occasion at least, to make the examination and measurement according to a set routine. The patient should recline upon an adjustable back-rest, with one vertically placed pillow supporting the head and shoulders. Oblique illumination is helpful, as shadows upon full veins and areas of venous pulsation facilitate their recognition.

The external jugular veins, being largely superficial in their course, are the easiest to observe, but where they are visible other veins, such as the anterior jugular, may be used to confirm the level of venous filling. The minimal level (i.e., in inspiration) should first be identified with the patient lying midway between the vertical and the horizontal. A measurement is taken and confirmed by examination of the veins on the other side; if there is a discrepancy a mistake has been made. After this, by adjusting the back-rest, the head and shoulders should first be raised and then lowered below the original position and further measurements made; these should all closely agree, and the average figure can then be accepted as the measure of venous pressure.

The instrument can be obtained from Messrs. Chas. F. Thackray, Ltd., Park Street, Leeds.

Medical Memoranda

Kidney Tumours in a Child and her Grandmother

The occurrence of an embryonal tumour of the kidney in a child 2½ years old and of a hypernephroma in her grandmother, aged 67, must be rare enough to be worth recording.

CASE REPORT

The Child.—Jean X., aged 2½, was seen in January, 1944, giving a history of slight haematuria two months previously. Examination showed a tumour occupying the whole left side of the abdomen and reaching across the midline anteriorly and to within two finger-breadths of the pubis. A diagnosis of Wilms's tumour was made and a pre-operative course of deep x-ray therapy was started. A maximum tumour dose of 3,150 r in 22 days was given to the left abdomen (B.J.). The mass regressed to one-third of its original size, and nephrectomy was performed (Mr. C. C. Holman) on Feb. 22. The tumour measured 12×11×8 cm. Macroscopically normal kidney structure was seen at the upper pole of the mass, which contained large cystic areas. The pathological report (Dr. H. I. Coombs) on the specimen was as follows: "The histology has been profoundly changed by the radiation, but numbers of small tubules and structures containing invaginations of stroma suggesting primitive glomeruli can be seen. These are separated by dense fibrotic stroma, but scattered foci of more primitive 'mesenchymal' tissue characteristic of a Wilms's tumour are also present."

The child made an uneventful recovery, and a post-operative course of deep x rays to the abdomen and mediastinum followed, 1,700 r being administered in 21 days. Apart from whooping-cough in November, 1944, she was well until February, 1945, when

mediastinal metastases were shown on an x-ray film. These appeared with further x-ray treatment. The child's condition improved temporarily. She died on July 21, 1945, eighteen months from the beginning of treatment.

The Grandmother.—Jane X., aged 67, is the paternal grandmother of Jean. She was first seen in January, 1946, suffering from pro haematuria. She said she had had similar haematuria three and five years previously. Examination showed a large mass the right loin extending nearly to the midline anteriorly and below the level of the umbilicus. Nephrectomy was performed by one of us (A. R. B.) on Feb. 8, 1946. Convalescence was uneventful, and she left hospital on Feb. 26. The pathological report (Dr. R. M. Heggie) was: "Histologically the tumour subm presents the classical features of a hypernephroma showing characteristic large cells and delicate vascular stroma. The arrangement of the epithelium is of the solid type." When last seen, in July, there was no sign of recurrence and she was doing housework.

COMMENT

Without inferring any significance in the occurrence of relatively rare tumours in child and grandparent, one can help wondering whether Nicholson's assertion (see Stan Cade's *Malignant Disease and its Treatment by Radium*, 1 p. 910) that "Wilms's tumours . . . are malformed kidneys does not find substantiation in these cases. It seems also worth mentioning that but for the follow-up clinics held at this hospital and the National Radium Commission registration cards, coincidence would not have been found, as the most persistent history-taking in the case of the elder patient did not provide any information of kidney disease in the family.

We are indebted to Mr. C. C. Holman for permission to mention the case, and to Drs. H. I. Coombs and R. M. Heggie for the pathological report.

A Case of Refractory Anaemia

Cases of pernicious anaemia which are refractory to parent liver therapy are occasionally encountered and have been classified by Davidson *et al.* (1943). A year after the introduction by Davis *et al.* (1943) of proteolysed liver for the oral treatment of megalocytic anaemias Davis and Davidson (1945) reported on its effectiveness in the treatment of refractory anaemias, particularly those with megaloblastic erythropoiesis. The following case illustrates how a typical Addisonian pernicious anaemia was treated successfully with oral proteolysed liver when it had failed to respond to parenteral liver extract.

CASE REPORT

A married woman aged 68 was first seen at the Nelson Hospital on April 24, 1945, having suffered from breathlessness, palpitation and swelling of the ankles for five months. On examination she showed the usual manifestations of severe anaemia, and her blood picture was typical of pernicious anaemia: haemoglobin, 40%; cells, 1,670,000 per c.mm.; colour index, 1.2; white cells, 5,000 per c.mm.; a blood film showed anisocytosis, megalocytosis, poikilocytosis. She was referred back to her own doctor, who gave her intramuscular injections of "hepatab" 2 ml. three times a week for six months and then every ten days until she returned a year later. Her condition improved at first but was followed by a gradual deterioration. The only blood count during this period (on May 19) showed no response to the liver.

She was seen again on May 16, 1946, having felt progressively worse since the previous Christmas, and was admitted three weeks later. On examination she presented the characteristic clinical picture of pernicious anaemia, with brown pigmentation, jaundiced smooth tongue, enlarged liver, and palpable spleen, and with congestive heart failure superadded. A full blood count on May 16 showed: red cells, 950,000 per c.mm.; haemoglobin, 25%; colour index, 1.3; reticulocytes, 3%; a blood film showed marked anisocytosis and poikilocytosis, with a few normoblasts, macrocytes and ghost cells.

Urine examination revealed no abnormal deposit or organisms. There was no free acid in the fasting gastric juice or after injection of histamine. Red cell fragility, normal. Van den Bergh reaction direct, negative; indirect, 4 mg. per 100 ml. The specimen obtained on sternal puncture was not rich in cellular material, but the primitive red cells were of megaloblastic type. Hippuric acid test: 3 excreted after two hours (normal, 50%). The fat content of dried faeces was normal. A barium meal followed by screening showed a normal stomach and duodenal cap. No occult blood present in the stools, and the Wassermann reaction was negative.

To check the potency of her previous liver injections the patient was given "anahaemin" 2 ml. intramuscularly on May 20, but there was no reticulocyte response. On May 24 the treatment was changed to one tablespoonful of proteolysed liver by mouth; marmite daily. Her clinical condition improved satisfactorily; she was discharged five weeks after the commencement of treatment. The evening temperature ranged between 100° and 102° F. (37° and 38.9° C.) during the first week after admission, 99° and 100° (37.2° and 37.8° C.) during the second week, and was normal at the third week. Her blood counts showed marked and rapid progress; after the first three weeks of treatment the haemoglobin

increased by 31%, and the red cells by 2,300,000 per c.mm. there was no apparent reticulocyte response. She was re-examined as an out-patient on July 3, when she felt well. The jaundice had vanished, the filiform papillae had appeared on her tongue, there were no signs of cardiac failure, the liver and spleen were no longer palpable. The result of latest blood count (July 22) was: haemoglobin, 80%; red cells, 10,000 per c.mm.

With thanks to Dr. A. J. Beard for permission to publish this case, and Dr. J. M. for the laboratory investigations.

Chicken-pox Eruption Treated with Benzyl Benzoate

During the early part of this summer a fairly extensive outbreak of varicella occurred in this district. I had noticed during the latter part of my service in the R.A.M.C. that pruritic skin eruptions, of whatever nature, were very largely treated empirically with benzyl benzoate, and with considerable success, at any rate so far as the itching was concerned. Accordingly, remembering how unsuccessful the usual applications habitually proved, it was decided to use benzyl benzoate in the itching pustules in this epidemic, and 16 cases in all were treated with it. It is not too much to say that it acted as a charm, and by controlling the scratching may have done nothing to shorten the convalescence. While this is too small a series on which to base any firm conclusions, the results were striking enough to make it seem worth while recording them, in the hope that they will be confirmed by others who may give treatment a trial.

The method was as follows: A complete application of the emulsion was made to all the affected areas, except the hairy part of the scalp, on successive days. For the scalp lot. crinoline is used and found to be satisfactory. After treating three or four cases patients were warned that they must not expect relief from the irritation until anything up to 24 hours after the second application, and, by the same token, that the parent failure of the first application was no excuse for omitting the second. Relief occurred on the average in about 24 hours after the second application, and thereafter was complete. The first four cases were advised to continue the application to any fresh pustules or areas where there was still irritation; but it was quickly evident that two applications properly made were sufficient to complete the treatment. It was well recognized that many skins, particularly those of children and the fair-haired, are sensitive to benzyl benzoate. Luckily no complications occurred, and it is thought that experience may show that reaction to the drug is rare except where application has been constantly repeated. The following is a record of the most striking case in the series.

The patient was a male aged 46, who had the most extensive eruption I had ever seen, and was running a temperature up to 2.6° F. (39.2° C.). He was in great distress from the irritation, and very disappointed when he got no relief from the first application. However, he was persuaded to persevere, and the second application was given about 9.30 a.m. on the following day. By that evening he had complete relief, and was so delighted that nothing would stop him plastering himself with the emulsion from time to time, to prevent recurrence, as he thought. He had no further trouble and recovery was rapid.

A brief analysis of the cases is given in the following table.

Case	Sex	Age (years)	First Seen (days from onset)	No. of Applications	Relief of Irritation (hours from 2nd application)
1	F.	6	Day of onset	2+	About 12
2	M.	4	"	2+	" 24

Reviews

PHYSIOLOGY OF FOOD AND NUTRITION

Food and Nutrition. By E. W. H. Cruickshank, M.D., D.Sc., Ph.D., M.R.C.P. (Pp. 326. 16s.) Edinburgh: E. and S. Livingstone Ltd. 1946.

This is a brief survey of the present state of our knowledge on the physiology of food and nutrition written for the general medical reader, although it is so clearly and simply written that the educated layman should have no difficulty whatever in following it. A number of historical anecdotes add to the interest of the book. A prominent feature is a discussion on the impact of the war on problems of national nutrition and a survey of the rationing system. There are chapters on the energy requirements of man, the basic foodstuffs, minerals, vitamins, the planning of diets, and the dehydration and preservation of foods. Each chapter is followed by a short list of references. The book is illustrated by a number of graphs and photographs, one or two of which are poorly reproduced. In the chapter on dental caries the impression is given that lack of vitamins A, D, and C is a contributory factor. There is no evidence that once the teeth are formed human dental caries results from a deficiency of these vitamins. However, this is only a minor criticism of an excellently planned, topical, and very readable book.

THE EMBRYONIC MIND

The Embryology of Behaviour. The Beginnings of the Human Mind. By Arnold Gesell, M.D., Ph.D., Sc.D., in collaboration with Catherine Amatruda, M.D. (Pp. 289; 391 illustrations. 21s.) London: Hamish Hamilton Ltd. 1946.

Dr. Arnold Gesell has extended his observations backwards, so to speak, and his latest book, written in collaboration with Dr. Catherine Amatruda, deals with *The Embryology of Behaviour*. It happened that the World's Fair hospital had a special unit for demonstrating the most modern methods for the care of prematurely born infants and here, during the summer of 1939 and 1940, a hundred babies were admitted (from various hospitals in New York City) with weights ranging from 800 to 2,100 grammes. Gesell's well-known methods of observation (and photographic recording) were adapted for these "foetal infants," as he calls them. His records, together with a study of what is known of the movements of foetuses and the work of such observers as Barcroft on particular problems, enable him to build up a fascinating picture of the development of behaviour, as orderly and documented in many respects as, for example, the story of the development of the heart. That there is a wide variation in the early stages, as in the later, is freely admitted, but a convincing pattern of what is termed in the book's subtitle "the beginnings of the human mind" really does emerge. Much that has been written of intrauterine psychology and even of early postnatal life is singularly unconvincing. This can never be said of Gesell's patient observations, and at a time when the whole field of embryology appears to be enjoying a renaissance it is fitting that this study of the embryonic mind should be included. Good appendices, selected bibliographies, and well-chosen illustrations make this an admirable monograph.

TREATMENT OF DIABETES

The Modern Treatment of Diabetes Mellitus. Including Practical Procedures and Precautionary Measures. By William S. Collins, M.D., and Louis C. Boas, M.D. (Pp. 514; illustrated. \$3.50 post paid.) Illinois: Charles C. Thomas. 1946.

This is a large, comprehensive book on nearly every aspect of diabetes, written by two New York doctors, little known in England as specialists in that subject. It is quite a new, fresh, and interesting production. Its main difference from other American standard textbooks is the profusion of the illustrations and charts, which include many good coloured pictures of clinical conditions, such as gangrene, peculiar to diabetes. In the introductory historical section—an unusual feature—there are portraits of the main innovators from Willis to Banting.

A large appendix on the detailed technique of urine and blood chemical estimations is unusual in a book for general practitioners, and a very detailed section on insulin syringes and injections includes nearly 30 illustrations. Perhaps most interesting is the full description of the Busher automatic injector whereby the timorous can "shoot" themselves with an insulin gun—a neat but time-consuming gadget. It is practically unknown in England but would be useful for many children.

A large chapter of 70 pages is devoted to diseases of the peripheral arteries and all pathological processes, and mechanical devices such as the "paevex" apparatus are described and illustrated in great detail. There is, however, little critical appraisal of their relative virtues and uses, which is not surprising in view of the widespread scepticism brought about by their failure to improve diabetic arteriopathy. There is no justification for including on p. 283 the night cramps of a juvenile diabetic as a form of "claudication."

Though a large part of the book is filled with these elaborations there is room for all the routines of diets, tests, insulin dosage, etc., to be thoroughly dealt with. But very often these vital matters are left on a vague and theoretical basis where the practitioner is likely to be lost. If, for instance, he looks in the index for the initial dose of insulin to give his patient, he is only told that, if the case is moderately severe, he should give 1 unit for every 7 grammes of available glucose in the diet, perhaps 20-30 units a day; and if it is a severe case, 1 unit for every 2 grammes available glucose, perhaps 100 units a day. This is not very practically helpful, and what is the poor doctor to do faced with the infrequent diabetic? It is well recognized that no one can predict the necessary dose of insulin, that it is a matter of trial and error, and simple rules are necessary for the beginning of treatment. But, minor criticisms apart, this is a book which every diabetician must read, otherwise he will miss much.

RHEUMATIC DISEASES

Symposium on Rheumatic Diseases. Medical Clinics of North America. New York Number. (Pp. 730; 115 illustrations. 75s.) London: W. B. Saunders Company, 1946.

This is the May number of the well-known *Medical Clinics of North America* which are issued by subscription six times a year. The foreword is written by Prof. Russell L. Cecil of Cornell University who points out that World War II has lent special significance to this disease group, which formed a major problem within the field of internal medicine. The American Army established three special hospitals for rheumatic diseases where unusual opportunity was presented for their study, and several of the papers in this volume are from these centres, of which the chief was the Army and Navy Hospital, Hot Springs, Arkansas.

Hench and Rosenberg contribute a long paper on recent advances in the treatment of rheumatic fever with special reference to sulphonamide prophylaxis and intravenous therapy. From their studies they conclude that the former constitutes a notable advance in the control of rheumatic fever, while vaccine prophylaxis is of uncertain value and is not to be recommended. They evaluate the methods of controlling airborne streptococcal infection and reiterate the value of conservative views on the employment of rest in this disease.

The problem of dosage in the administration of gold salts for rheumatoid arthritis is exhaustively discussed by Prof. Cecil, who confirms the wisdom of the modern tendency to reduce dosage and to spread it over a longer period. X-ray therapy is discussed in some detail by Dr. Richard Freyberg, and the recognition and management of gout by Dr. John Lansbury of Temple University. The scope of physical therapy in chronic arthritis is admirably reviewed by Dr. Kovacs, and the contribution which the orthopaedic surgeon can make in this field is set out in succinct and interesting fashion by Prof. Irvin Balesweig of Cornell. Among other matters dealt with are the cholesterol content of urine in arthritis, toxic hepatitis during gold-salt therapy, Still's disease, menopausal arthritis, and the susceptibility of the host in rheumatic fever.

The format of this volume is uniform with others in the series; they are easy to read, and provide an up-to-date summary of their subjects so far as the United States is concerned. A certain number of references to British work will, however, be found in the bibliographies which follow each chapter.

Notes on Books

Motor Disorders in Nervous Diseases, by Drs. ERNST HERZ and TRACY J. PUTNAM, is published in New York by the King's Cro Press. This small book is really an illustrated guide to the examination of the motor signs of disease of the central nervous system. The authors have carefully omitted everything else, as it is primarily meant for use with a series of cinematograph films of disorders of movement which they have made. Most of the 250 illustrations are stills from these films, and some of them are serial strips taken from them. Although they are technically excellent they are poor substitutes for direct observation of a patient, or even for a moving picture itself. Paralysis agitans loses everything in a photograph, the trigeminal nerve is a poor thing without its sensory roots, and an account of the examination of motor functions alone makes an unsatisfactory approach to neurology. As a descriptive syllabus to the set of films, for which it was intended, the book is no doubt admirable, but, except in so far as it presents aspects of neurology already available in comprehensive textbooks, it does little to supplement clinical teaching at the bedside. Copies can be had from the Oxford University Press, London, at 20s.

Road Accidents and Alcohol, being the Rae Memorial Lecture, 1946, by Dr. WILLIAM M. FAIRLIE, has been published with addenda as a 6d. pamphlet by the National Temperance League, 33, Bedford Place, W.C.1. The lecturer was divisional surgeon to the Metropolitan Police for 23 years, and the gist of his well-presented argument will be found in two sentences on p. 12: "The question arises what amount of alcohol, if any, is it safe for the motor driver to take? There can be but one answer to this—NONE."

Preparations and Appliances

TIP-UP HOSPITAL TROLLEY

Dr. C. E. D. H. GOODHART writes from St. Helier Court Hospital, Carshalton, Surrey:

There are many occasions when a theatre trolley which can be made to tip is of the greatest value. The trolley shown in the accompanying photograph was designed in conjunction with Mr. Selleck, our engineer, to whom our grateful thanks are due. It was made in the hospital's workshops of 1 in. conduit and tinned sheet steel. It embodies the following features.

The weight of the patient causes the trolley to bed down on rubber cushions, from which it is released by depressing a foot pedal, when tilts of up to 30° in either direction can be obtained. To prevent the patient sliding off, two leather straps and adjustable shoulder-pieces are provided. The latter when not in use are locked away under the trolley. Finally, a movable rod with a hook has been added, from which a bottle containing blood, etc., can be suspended.

I wish to thank Dr. Miller, our pathologist, for his kindness in taking the photograph.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY NOVEMBER 23 1946

HEALTH SERVICE IN RHODESIA

Southern Rhodesia is the latest British colony to contemplate a National Health Service. It is not much more than fifty years since the first British doctors entered the Mashonaland plateau, accompanying the pioneer column of the British South Africa Company, and established the first hospital at Salisbury. Now the colony is seeking a service, based somewhat on the model foreshadowed by British legislation, with Minister of Health, National Health Board, Regional Health Councils, Area Health Committees, and the rest of them. In the young and expanding country south of the Zambesi health services have "just grow'd." The State, there as elsewhere, has come into the picture to fill the gaps when these obtruded themselves. Much excellent work has been done for the Africans by Christian missions. For the Europeans, and indeed for the Africans too, other voluntary work has had a different derivation—namely, the State lotteries, which have subsidized bilharzia research, built a hospital for nervous diseases at Bulawayo, established an orthopaedic service, and organized blood transfusion. The State has furnished free curative services for the obviously needy, especially, of course, the African population, and for Europeans it has maintained Government medical officers in areas which could not support a private practitioner. The State runs nearly all the hospitals in Southern Rhodesia, and, with very minor exceptions, all the maternity homes.

The difficulty is the inadequacy of medical service for the African population. For every European there are about 20 Africans, and, while the curative services for the Europeans may be adequate, those for the Africans are fantastically deficient. Even in twenty years' time, when, under the long-term proposals now being put forward, there will be a European full-time Government medical officer in every native district, assisted by one or more fully qualified African doctors, there will still be only one medical man to perhaps 20,000 Africans. In some districts at present there is one doctor to 50,000 or 100,000 potential patients—an impossible situation even if the population were mainly healthy. Domiciliary treatment for Africans is practically non-existent, and even out-patient treatment at hospitals is largely provided by orderlies who sort out the cases for the visiting doctor. Thousands of sick Africans never see a doctor at all.

A Government Commission, under the chairmanship of Prof. C. F. M. Saint, has been inquiring into the provision of an organized National Health Service in conformity with the modern conception of "health," and has submitted its report (a summary of which appeared in our

Supplement of Oct. 26) to the Legislative Assembly of Southern Rhodesia. The first principle it lays down is that the State must accept responsibility for the health of the African. This being accepted, it seems difficult to exclude the remaining 5% of the population. Whatever the financial arrangements of the service, the cost must be borne mainly by the better-to-do, and to leave these persons out of benefit would mean that they paid twice, once in the form of taxation, and again for such service as they might personally need. Again, if these people were left out of the scheme it would be immediately branded as an inferior service. For the African population there can be no economic alternative to a full State salaried service. For the European population the position is different, largely because they have been imbued with the principle of free choice of doctor (though in fact outside the big towns that is largely illusory) and the importance of the doctor-patient relationship. The Commission therefore proposes that curative services be divided into two parts. Surgical and medical treatment in hospitals, and consultant, maternity, x-ray, and laboratory services, will be provided free to everyone by means of a full-time salaried staff, but general practitioner and dentistry services for non-Africans will be left to private practice. They will be paid for by the individual himself up to a certain prescribed maximum each year. The scheme is that a man will pay for his medical services up to 2% on the first £500 of his income, at a slightly higher rate on the second £500, and so on, so that a person with just under £1,000 a year will have to pay £20 for medical services for himself and his family before his personal responsibility ceases and the cost of any further service is met from State funds. The individual will be relieved of excessive costs falling in any one year, and the general practitioner, paid on a fee-for-service basis, will derive part of his income from the patient and part from the State. This plan will make it necessary for the Government to ordain uniform charges for medical services, and there is an implication that if these charges are pitched too high the arguments in favour of a whole-time salaried general practitioner service will be strengthened. Meanwhile to obtain the increased number of Government medical officers who will be necessary the Commission recommends a higher salary scale, which it is thought will attract as many as the colony can afford.

It will be interesting to learn what is the reaction of the Rhodesian general practitioner to these proposals. On the one hand, he will have fewer bad debts and less expense and delay in debt collection, and he may expect some increase of practice, because people will not be deterred to the same extent from coming to the doctor by the possibility of incurring heavy costs. He will also, if another recommendation goes through, have access in certain places to central consulting rooms and equipment. On the other hand, he stands to lose his midwifery practice and the practice he may have been accustomed to carry out at the local hospital. Apparently the question of the general practitioner's following his cases into hospital is a sore one. General practitioners, it is said, have invaded Government hospitals with their private cases, which have been nursed under their orders by Government nurses and

physicked on their prescriptions from Government stocks, and the patient has paid the normal fee to the private doctor and has made only a sub-economic payment to the Government. All that is going to be stopped if the report of the Commission is adopted. The same applies to maternity homes, where cases will be attended by salaried obstetricians. Two members of the Commission of five stood out for the opening of maternity homes to general practitioners, but the majority went the other way. If a patient wants the services of a private practitioner in hospital or maternity home the full economic rates will have to be paid.

Like many good things—and bad things, too—in the British Empire and outside it, the proposals are a compromise. They will please neither the advocates of a full State service nor those who favour unrestricted private practice. They extend the scope of the State, but leave a wide area to non-State agencies. They reduce the burden of medical expenditure falling upon the individual, but they leave him to bear an appreciable part of it. In the field of administration they provide for public participation in health affairs, but executive control in most respects would be left in the hands of the Government. They create regional authorities, but allow the municipalities to continue most of their existing functions. Their finance is planned on generous lines and yet with due recognition of the limited resources of the colony. One line of compromise which does not appear to be mentioned in the report, though it has many examples in the British system, is the part-time employment of private practitioners by local authorities. But the differences in conditions of medical practice between Great Britain and Southern Rhodesia must be borne in mind. To mention one difference only, the system whereby our voluntary hospitals are staffed by physicians and surgeons who give their services without payment, and in return gain experience and prestige which enables them to command a wide practice and high fees, is quite out of the question in the Rhodesian scene.

RUBELLA AND CONGENITAL ABNORMALITIES

The considerable number of reports showing an association between rubella during pregnancy and the subsequent birth of a child with a congenital abnormality leave little room for doubt that such an association exists.¹ The practical and theoretical implications have been fully discussed by Ida Mann, N. McA. Gregg, Swan, and Scholes at a symposium held by the Ophthalmological Society of Australia.² Two questions still remain, however: how frequently does the association exist, and in what proportion of all children thus defective is rubella the cause? Conte, McCammon, and Christie³ have endeavoured to answer such questions by reviewing their hospital records for all cases diagnosed as congenital heart disease, congenital cataracts, deaf mutism, microphthalmia, aniridia, hydrocephalus, and mongolism during the period 1939–44. The survey dis-

closed a total of 120 such cases, and the mothers of them were approached by means of a written question. Sixty-one parents replied—not, perhaps, a very satisfactory proportion—and of these five gave a history of rubella during the pregnancy. In the first (one of twins) the mother had contracted rubella in the seventh month, but in the other the times of occurrence were 2 weeks, 6 weeks, 2 months and 3 months. There were four examples of congenital cataract, four of congenital heart disease, three of cerebral aplasia, and one of mongolism; all had more than one abnormality. To show that the association was more than casual the “rubella case rate” of 4.2% (assuming that mothers who did not reply did not have rubella) was compared with a rate of 0.4%—the author’s estimate from morbidity statistics of the “rate of measles in the female population of the child-bearing age group.” The large disparity between the two figures is additive evidence in support of an association. (The first rate is based upon “actual” mothers, whereas the second is based upon “potential” mothers, so one might conjecture an even greater disparity.) Fox and Bortin⁴ have tackled the same question in a different fashion. During 1942–4, out of a total of 22,226 cases notified as rubella there were 152 where the patient was a married woman. Of 152 of the women who had been followed up 11 were found to have had the disease during a pregnancy—in five before the second month, in four before the fourth month, and in each in the seventh and ninth month. Only one of the mothers, who had rubella during the first month, later gave birth prematurely to a hydrocephalic stillbirth; otherwise all the other children were normal. One interesting case brought to light in the investigation was of a mother who, eight years previously, gave birth to a child with bilateral congenital cataract after a normal pregnancy. On the present occasion when rubella occurred the child was normal.

Such figures permit broad answers to the two questions posed: first, that rubella during the early months of pregnancy has something less than a 10% chance of damaging the foetus; and secondly, that of all such congenital abnormalities in children some 5–10% may have their origin in damage by virus during intrauterine life. One would naturally expect that these results might be capable of extension to other viral infectious diseases; but in a survey of 92 cases of antepartum infection traced by Conte and his colleagues³ only three were examples of virus diseases (rubella, chicken-pox, and mumps), and in none was there any congenital abnormality in the child. As it happened, two out of the three occurred late in pregnancy. Swan reported one case presumed due to mumps and another to influenza, and Rones⁵ has recorded one where the maternal disease was morbilli.

Such work should result in a complete re-examination of the aetiology of congenital defects. The range of the inquiry may well be wide, for about two-thirds of the cases thus far recorded have also been mentally defective. Earlier investigations all seemed to point to the conclusion that extrinsic factors played little part in initiating congenital

fects, and that the condition of the germ-plasm at the time of fertilization was the over-riding consideration.⁷ Indeed, in view of the very natural desire on the parent's part to want to blame some environmental factor rather than to admit some apparently inherited imperfection, it seems strange that the effect of a maternal infection escaped notice as a traditional cause. Guerry,⁸ it is true, commenting on a further two cases with congenital glaucoma, alleges that there is "an old-wives' tale well known among the laity to the effect that if a mother has German measles while pregnant it will settle in the baby's eyes." But such superstition seems to have been so deeply buried that it has become quite forgotten. It is, however, abundantly clear that rubella itself does not provide the entire explanation. One is tempted to conjecture that many other intrinsic factors should be included in the range of inquiry and that the recent suggestion that Rh incompatibility may be a cause of mental deficiency⁹ further extends the list of possible exciting environmental factors.

PLEBISCITE SECRET

Everyone who returns the Plebiscite form will sign his or her name on it. A correspondent asks whether these signatures will be confidential, and whether there would be any risk that the Minister or Ministry of Health would have access to the names of those who write "No" on the form. I feel," he writes, "the need for an assurance that the voting will be either in fact secret or if not that any papers, records of names, votes, etc., will be absolutely destroyed immediately after the count, and revealed by no one to anyone." It is possible that other doctors may also have some lurking fear of the consequences that may follow their decision to write either "Yes" or "No" on the plebiscite form. We would therefore assure any who remain in doubt that the voters' names will be kept secret and will not be revealed to any Government Department. When the issue has been settled the Plebiscite forms will be destroyed. It is necessary that the Plebiscite form should be signed, as in university voting, as a safeguard against the risk of duplicate returns.

That the question has been asked in all seriousness is an illustration of the distrust of the Ministry of Health that prevails in the profession and of the fears that medical men have of a service controlled by the Ministry. This distrust is deep-rooted and the result of the profession's experience with the Ministry of Health since 1919. The present Minister cannot be said to have gone out of his way to remove the grounds of this distrust. His attitude of mind was revealed in the cheap jibe about senior members of the profession which he made when recently addressing the British Medical Students Association. If he is to secure that co-operation from the profession which he knows is essential he will have to show himself more appreciative of the wishes and fears of the medical profession than he has been so far. If the majority of the profession say "No" on their Plebiscite forms then the Minister will have no one else but himself to thank for such a refusal to operate the new Health Service Act, because this is what the answer "No" will mean. If the majority say "Yes" the Minister may be assured that very many of those saying "Yes" will be saying it with some reluctance. This "Yes" may become converted into a "No" to the

question, "Do you want to enter the Service?" which may be put to the profession shortly before the appointed day and when the full details of the Service as expressed in Regulations and Orders are known. Once again we urge all doctors to vote and to return their Plebiscite forms.

GALVANISM FOR DENERVATED VOLUNTARY MUSCLES

The influence of electrical stimulation in the treatment of lower motor neurone lesions has been closely studied by Prof. Seddon and his co-workers, in the Department of Orthopaedic Surgery at the University of Oxford. The importance of rest, relative rather than absolute, is dealt with by Mr. Norman Capener in the opening pages of this issue. It is well known that muscle atrophy begins very soon after denervation and that associated with it is fibrosis of the affected muscles. Gutmann and Guttman have shown by animal experiments that galvanism can prevent wasting after denervation provided it is applied soon.¹ Although it is impossible to prevent the atrophy that occurs in the first few weeks after denervation, the muscle fibres remain large and interstitial fibrosis is reduced to a minimum in treated muscle. Furthermore, if re-innervation takes place the maximum functional recovery ensues. If on the other hand the denervated muscles receive no treatment the individual fibres shrink rapidly, fibrosis occurs to a much greater extent than it does in treated muscle, and even after re-innervation the functional recovery may be bad.

Since animal experiments proved to be so promising a clinical assessment of the effects of galvanism on denervated muscle was made by Jackson² working at Oxford. Volumetric measurements of the hand were made, with industrial alcohol, on patients suffering from peripheral nerve lesions. These cases were divided into groups according to the type of lesion and the time which had elapsed between the receipt of the injury and the initiation of treatment. Ninety stimuli, at the rate of thirty per minute, were given with each treatment for six days a week in the treated cases. These were compared with a similar series which received no galvanism. The observations were limited to the period of complete paralysis.

It appears from these investigations that in the first four hundred days a steady loss in volume occurs in untreated muscles, whereas in those receiving galvanic treatment wasting is almost completely prevented except during the first hundred-day period. Moreover there is some evidence to show that even during those hundred days galvanism tends to minimize wasting. It can therefore be concluded that the course of wasting as it occurs in human muscle resembles that found in experimental animals, and that the sooner treatment is started after the receipt of the lesion the better. Electromyographic observations have shown that the delay between the appearance of motor units in a muscle and the first flicker of voluntary contraction was less in those cases in which galvanic stimulation had been carried out.

Stimulation should be started as soon as possible after denervation even if this involves cutting windows in plaster casts to gain access to areas where it can be applied. Galvanic stimuli should be administered ninety times daily at the rate of thirty per minute, with an interval of one minute between each group of thirty stimuli to permit recovery from any possible muscle fatigue; and this treatment should be applied at least six days a week. For smaller muscles such as those of the hand the value of such measures is not in doubt; where large muscle masses such

as those of the thigh are involved tolerable doses of galvanism may affect only the more superficial fibres, and this form of therapy will not be so effective.

CANCER CONTROL IN THE U.S.A.

The plan for an accelerated cancer-control programme is provided in a report on cancer facilities and services issued by the U.S. Public Health Service of the Federal Security Agency. Prepared by a committee of the National Advisory Cancer Council, the report contains specific recommendations concerning medical education and control programmes for the disease which to-day ranks second as a cause of death in the U.S. The special committee was appointed in November, 1944, by Dr. Thomas Parran, Surgeon-General of the U.S. Public Health Service, in anticipation of a post-war increase in cancer control activities. The report deals in turn with medical education in cancer, basic elements of a cancer programme, and basic information for use in studying and planning State-cancer-control activities.

The committee recommends more comprehensive and better integrated courses in cancer at medical schools; an increase in the number of centres prepared to give post-graduate training in cancer; and the continuation and expansion of the various kinds of cancer-education activities for practising physicians that have been conducted in a number of communities. It further recommends that the National Cancer Institute should aid in the development of a few cancer centres strategically located geographically, in association with one or more medical centres, and available to any patient regardless of ability to pay. It suggests that such centres would serve as guides in developing plans that could be applied anywhere in the country to give cancer patients the best that medical science has to offer in the way of diagnosis and treatment. Expansion of the research work of the National Cancer Institute is advised, including the training of research fellows and grants to aid research in other institutions. Also recommended is assistance from the Institute to State health departments and other agencies in developing programmes which will provide a State with an adequate cancer service. The report describes the basic elements of such a service as statistical research to determine the extent of the cancer problem; educational activities for doctors, dentists, nurses, and the general public; medical facilities and services, including cancer prevention or detection clinics, tissue diagnostic services, diagnostic and treatment clinics (one for approximately 50,000 population), an adequate number of hospital beds, and facilities for the care of the advanced cancer patient either in his own home or in an appropriate institution. Close co-operation is urged between the National Cancer Institute and voluntary agencies in the development of cancer-control activities. It is further recommended that if present legislation does not give the National Cancer Institute the authority to carry out the committee's recommendations additional legislation and necessary appropriations should be sought.

PERICORONARY NEURECTOMY FOR CORONARY DISEASE

In his Harveian Oration, published elsewhere in this *Journal*, Sir Maurice Cassidy draws attention to the increasing prevalence of coronary disease. In America there has been a similar increase, and the surgery of coronary disease with angina has been the subject of much experimental work.

Sensory disturbances, vasomotor reactions, and mechanical interference with the coronary blood flow all play a part

in coronary disease. Surgical operations have not so far been designed to attack all these abnormal conditions and for this reason have often proved disappointing. Fauteux¹ has recently pointed out that arteriosclerotic disease of the coronary arteries is similar to that of the extremities and has therefore suggested that surgical methods used in the treatment of peripheral vascular disease could be applied to coronary disease.

In cases of senile gangrene ligation of the popliteal vein has proved of value, and in 1937 Gross, Blum, and Silverman² reported experiments showing that occlusion of the dog's coronary sinus increased the blood supply and reduced the incidence of infarction following ligation of a coronary artery.

Since 1939 Fauteux has ligated the great coronary vein in 9 cases of angina pectoris, all with a history of coronary thrombosis. One death followed operation, and one other patient has since died. Of the 7 survivors 3 are alive after five years, and 4 are alive four years after operation. All these patients are at work and enjoying life. Fauteux considers that the coronary venous ligation affects the natural development of a collateral circulation and improves both the nutrition of the heart and its functional capacity. The coronary nervous system is not modified by the ligation, and he feels that a logical extension of the operation should include an interruption of the nerves to and from the coronary vessels. This could be done by what Fauteux calls "pericoronary neurectomy," destroying the nerve branches reaching or leaving the left and right coronary arteries, since these branches are localized behind the pulmonary artery as well as in the nerve plexus over the ascending aorta. Experimental work on dogs seems to show favourable results, and the operation has been performed on one man. This patient, aged 45, had had a coronary thrombosis following attacks of angina. He made a good recovery after operation and up to six months later had been relieved of all anginal pains and had resumed work.

This paper is no more than a preliminary account of pericoronary neurectomy and the work on which it is based. It is clearly not possible to draw any conclusions from it, but the report of further experiences and of a longer follow-up will be awaited with interest.

BARRIER CREAMS

Dermatitis is a national problem, and for some time it has been one of the principal causes of disablement from industrial disease. Any scientific attempt to initiate new, or to improve old, methods for its prevention must receive careful consideration.

Barrier creams have been hailed as the answer to the problem of industrial dermatitis, and they are of value provided that they are well chosen and as well used. But an article in this issue on "The Evaluation of Barrier Creams" (p. 769) may serve to temper enthusiasm with a caution as to the need for ascertaining whether such creams can physically or chemically fulfil the claims that are made for them.

The application of special preparations intended to act as a barrier between the irritants of industry and the worker's skin originated as the result of personal observations by the workmen who long ago used such substances as mutton fat, Fuller's earth, china clay, or soap. It seems unlikely that the primary objective was the prevention of skin affections. More probably the practice arose and grew on account of the relative ease with which the signs of toil, and perhaps staining of the skin, were removed after

¹ *Amer. Heart J.*, 1946, 31, 260.
² *J. exp. Med.*, 1937, 65, 91.

ork was over. This is still one of the main qualities of barrier preparations; and in view of the number of creams which failed to gain a credit or even a pass on the evaluation standards of Sadler and Marriott it is salutary to remember this and to recall that provided it is non-irritating to the skin even an imperfect barrier which is used will be of more value than untouched perfection in the pot.

Recently, in the Patent Fuel Manufacture (Health and Welfare) Special Regulations of 1946, "barriers" were given statutory status by the requirement of the provision "a suitable cream or similar protective substance for the skin." Every works medical officer knows that it is one thing to provide a cream and quite another to ensure its use, and where the provision is voluntary there is nothing but persuasion. This will be undertaken with more conviction if it has been shown that the protective cream provided has the requisite chemical and physical qualities for the task. As Sadler and Marriott point out, the ultimate evaluation must be the measure of success attained in actual practice, and they suggest that this should follow preliminary weeding out of unsuitable preparations by retention tests, many of which could be carried out in a works laboratory or a factory medical department. Even with this scientific approach success in the prevention of occupational dermatitis is doubtful unless the full armour of protective measures is overhauled and reassembled. These measures are well known, and perhaps the most fundamental of them is to prevent, or reduce to a minimum, contact of the skin with the irritant, both by works procedure and by effective removal of irritants from the skin by washing. Medical supervision and nursing services will detect where the cloak of protection is defective. It must be admitted that the whole range of protective measures is of a deceptive simplicity, but nothing short of the concerted effort of management and workers in the daily carrying out of these measures is likely to bring success.

Barrier creams need evaluation not only of their physical and chemical properties but also in relation to other precautionary measures directed towards the prevention of dermatitis. The majority of the barrier preparations in use in industry are of proprietary manufacture, and discussion of the relative merits of named brands is therefore edged with legal hazards. This position may be clarified, however, now that the Pharmaceutical Society of Great Britain has undertaken, at the instigation of the Advisory Panel on Dermatitis in Industry set up by the Minister of Labour, to consider the determination of formulae for barrier preparations suitable for inclusion in the *British Pharmaceutical Codex*. The results of this work are awaited with growing interest.

MALNUTRITION IN FRENCH CHILDREN

A shortage of food supplies in the United Kingdom during the war was not allowed to affect the health of our school-children. Magee¹ has reported that as a result of an enlightened food policy for the whole nation and special allowances of milk and other food in the schools our children actually grew more rapidly and had better teeth than before the war. In other countries, however, where the food shortage was more serious or where rationing schemes were less well planned and conducted the children were not so fortunate. In countries such as Holland, Poland, and Greece they felt at one time or another the sharpest pangs of starvation. In France the situation was less severe, but ample evidence has been gathered showing that suboptimal nutrition caused a reduced rate of growth and an increased incidence of disease.

Dr. Harold C. Stuart,² of Boston, U.S.A., had excellent opportunities for studying the effect of malnutrition on the children in unoccupied France in connexion with his activities from 1942 onwards on behalf of the American Red Cross. He found that children in Marseilles were inferior to children of the same age in Iowa in weight, height, and length and development of their bones as measured by skiagraphy. This was in agreement with earlier statements by Youmans³ that the average food intakes of children in this town were 22% below estimated requirements for their age. In a later publication, however, Stuart⁴ concluded that the causes of the small stature found in about 50% of the French children must have existed before the war. He was unable to decide whether the factors mainly concerned were nutritional or congenital, but deficiencies in calories, animal protein, and vitamin D were suspected.

A recent paper by Dr. Laporte,⁵ also of Boston, is therefore interesting in showing that the dietary limitations imposed by the war had a direct effect on the growth of school-children in Paris. The records of 2,595 children equally proportioned between the sexes were surveyed, and means for the various ages were calculated for the years 1938 and 1944. For boys an average deficit in weight of 6 lb. (2.7 kg.) was found in 1944 as compared with 1938, while for girls the average difference was 3.5 lb. (1.57 kg.). In height the greatest difference for boys was 3.1 in. (7.9 cm.) at the age of 11 years, and for girls 1.5 in. (3.8 cm.) at 7 and 12 years. In support of Stuart's conclusion, however, the average heights for French children, both boys and girls, were less than those of American children even in 1938.

As a minor criticism of Dr. Laporte's studies it may be remarked that the differences in both weights and heights between 1938 and 1944 sometimes varied in a very inconsistent manner. Thus the difference in weight for boys at 6 years was 7.3 lb. (3.3 kg.), at 7 years 0.6 lb. (0.27 kg.), and at 8 years 4.1 lb. (1.8 kg.). Even the large number of subjects examined, therefore, admittedly not equally assorted in regard to age, did not produce the smooth curves which might have been expected in such a study; but these small flaws must not unduly detract from the weight of the evidence as a whole. In view of both stunting of growth and the increased incidence of active tuberculosis during the war years, which is also mentioned by Dr. Laporte, it is obviously desirable that France should strive to put her children's diet on a more adequate basis.

THE ADDISON LECTURE

A former student of Guy's Hospital has given a sum of money to establish what is to be called the Addison Lecture, the first of which will be given in the Physiology Theatre, Guy's Hospital Medical School, on Monday, Dec. 2, by Prof. E. C. Dodds, under the title of "Stories of Endocrine Research." The objects of the Lecture are to commemorate the work of Thomas Addison in endocrinology and to continue in this way the intimate connexion between Addison, Guy's, and one of the growing fields of medicine.

We regret to announce the death at the age of 79 of Dr. J. Shaw Bolton, the eminent psychiatrist, who was for 23 years medical superintendent and director of the West Riding Mental Hospital, Wakefield, and professor of mental diseases in the University of Leeds.

CORONARY DISEASE

PASSAGES FROM THE HARVEIAN ORATION*

BY

Sir MAURICE CASSIDY, K.C.V.O., C.B., M.D., F.R.C.P.

For many years I have been especially interested in cardiology, and I have been impressed, like many others, by the increasing prevalence of coronary disease. Even during so short a period as the last twenty years this increasing prevalence seems to be beyond question. In the year 1926, 64,465 persons died in this country of all forms of heart disease. Ten years later this number was almost doubled—126,584, to be exact. The figures for coronary disease are even more startling—1,880 died in 1926, 14,095 in 1936, and 19,496 in 1939. The crude death rate from all causes per 1,000 persons living fell from 22 in the decade 1851-60 to 12 in 1930, and has subsequently remained almost stationary at about that figure. The similar crude death rate from heart disease, and especially from coronary disease, has risen in a spectacular fashion during this period, and particularly during the last twenty years. In the case of coronary disease the figures increase rapidly year by year—48 per million living in 1926, 148 in 1930, 473 in 1939.

Part of this rapidly increasing death rate from coronary disease is no doubt attributable to the increasing age of the population. In 1900 there were 1,750,000 persons over 65 years of age in Great Britain; in 1937 there were over 3,750,000. It is true that the standardized death rate, corrected for ageing, for policy-holders of the Metropolitan Life Insurance Company of New York shows a 70% decline for diseases of heart, arteries, and kidneys in the years 1940-5, as compared with 1911-15. But this astonishing decline in mortality is for ages 1 to 74. When the figures for the different age groups are examined it is clear that the improved mortality affects chiefly persons up to the age of 25, and is no doubt attributable, in part at least, to more efficient treatment of the acute infections which are largely responsible for cardiovascular and renal deaths in this lower age group. Between the ages 35 and 64 the standardized mortality among men shows little or no decline in the past two decades, and there is in fact an increased mortality now as compared with the level reached in the early nineteen-twenties.

The crude death rates in America, without correction for increasing age of population, have increased as they have done in this country: thirty-five years ago cardiovascular diseases accounted for less than one-quarter of all deaths; now they account for nearly a half.

The Increase in Coronary Mortality

Part of this mounting coronary mortality has been ascribed by some to increasing accuracy of certification. But I cannot believe that this can play a very important part. The position here is very different from that in bronchial carcinoma, for example, where accurate diagnosis is largely dependent on refinements of investigation such as are afforded by bronchoscopy and radiography. Angina pectoris is one of the easiest of all diseases to recognize. Its clinical features have been well known to every doctor since Heberden recounted them before this College in 1768. In most cases electrocardiographic and radiographic investigations are superfluous diagnostic aids.

Certainly the clinical recognition of coronary thrombosis has till recently been hidden from us. Though first well described clinically by Herrick in 1912, its diagnosis did not become widespread in America till about 1920. Curiously enough, it was not until 1925 that McNee brought to the notice of physicians in this country the clinical picture of coronary thrombosis as first described by the American cardiologists, and the rapid increase in the certification of deaths from coronary thrombosis since that date must be partly attributable to this. Even so, I have the impression that coronary thrombosis is far more prevalent than it was. Looking through my notes of patients seen twenty or thirty years ago, I come across occasional cases where I failed to recognize the coronary thrombosis which now, on paper, is the obvious diagnosis. But such cases are

surprisingly infrequent. It is interesting to read Mackenzie's notes of Case 112, one of the 160 case records in his book on angina pectoris (1923). He describes this as "one of the most puzzling cases I have met." It is now evident to us that this patient suffered from at least two attacks of coronary infarction the second associated with pericardial friction, and that six months later the consequent myocardial degeneration brought on three attacks of acute pulmonary oedema, the last fatal.

It is odd, too, that coronary thrombosis figures so infrequently in the post-mortem reports of thirty years ago, despite the fact that the very astute morbid anatomists of those days were fully alive to the existence of this condition.

Consider, too, the clinical experience of great physicians of the past. In his book on angina pectoris James Mackenzie states that "380 patients consulted me for angina pectoris." Osler in his *Lumleian Lectures* (1910) says: "It is a disease for seniors to discuss, since juniors see it but rarely; indeed I had reached the Fellowship before I saw a case in hospital or in private practice. During ten years I did not see a case at the Montreal General Hospital and only one case at the University Hospital, Philadelphia. . . . A consultant in active practice may see 10, 15, or more cases in the course of a year and this is about the figure reached in this country by a consultant with recognized cardiovascular leanings." He goes on to say that he has now seen 268 cases, which included 42 "of the mild neurotic or pseudo form." Contrast these figures with those of the modern cardiologist, who counts his coronary patients by thousands rather than by hundreds, and remember that there was but one James Mackenzie, and one William Osler, whereas the modern cardiologist's name is legion. During the ten years 1898 to 1908 Sir Richard Douglas Powell saw 96 cases of angina, 26 of which he classified as vasomotor angina. Surely Osler, Mackenzie, and Douglas Powell were at least as competent to diagnose angina pectoris as are physicians of this generation!

Increasing Prevalence of Coronary Disease

What is the explanation of the increasing prevalence of coronary disease? In an attempt—and I confess at once a vain one—to find some answer to this question, I have analysed the notes of 1,000 cases of coronary disease, including both coronary occlusion and angina pectoris, seen in consulting practice. I have notes of approximately another 1,000 cases which I have not analysed. I was careful to include only those cases where I was reasonably certain that coronary disease was present. And here may I put in a plea for the abandonment of such terms as angina minor, angina innocens, and, worst of all, pseudo-angina? Either the patient has angina or he has not. If he has, we believe that some portion of his myocardium is ischaemic, usually as a result of coronary atherosclerosis with or without a coronary thrombosis or a subintimal haematoma. Syphilis is a rare cause of true anginal pain, and embolism a rarer cause still. A severe anaemia may play a part probably in association with some degree of coronary atherosclerosis, for I have never seen a severe anaemia cause angina in a young subject, though this happens quite commonly in the more elderly. Alastair Hunter, however, has described 12 cases of anaemic angina, of whom ten were women and five were aged 40 or less, the youngest being 31, which certainly suggests that anaemia alone may cause anginal pain.

Anginal pain is sometimes a symptom of rheumatic heart disease, but I have not included such cases in my series because in my experience they do not conform to the clinical picture of the atherosclerotic type, though we know that rheumatic infection may produce somewhat similar coronary changes. I have never seen a coronary occlusion complicate rheumatic heart disease, nor do I feel that anginal pain in a young rheumatic subject has the same serious significance as in the atherosclerotic patient.

We can conceive of the possibility of spasm of a healthy coronary artery producing a localized myocardial ischaemia with consequent coronary pain; but we have no proof that this does in fact ever happen, though we may suspect that an unstable vasomotor control may play a part in the clinical picture of the patient, familiar to us all, who suffers, perhaps for years, from anginal paroxysms of great severity provoked by trivial physical effort, and especially by emotion. Physi-

* Delivered before the Royal College of Physicians of London on Luke's Day, 1946.

examination may be surprisingly negative, and consequently these patients are often regarded as cardiac neuropaths till at last the diagnosis of organic coronary disease becomes only too clear, perhaps as a result of the sudden and unexpected death of the patient.

Some years ago I used to diagnose "vasomotor angina" not infrequently in patients who complained of anginal pain of typical distribution, this pain being provoked by effort, but especially by emotion, without physical signs of organic cardiovascular disease and with a normal electrocardiogram. Sometimes there was evidence of vasomotor instability, such as easy flushing, or Raynaud-like phenomena, or a history of migraine. But increasing experience has convinced me that sooner or later these patients present undoubted evidence of organic coronary disease. If the same amount of effort constantly provokes substernal pain or even discomfort, however slight, and if this discomfort disappears promptly with rest, I think we may assume with confidence some degree of coronary obstruction, however negative the findings may be.

As for that large heterogeneous group of so-called "false angina," we can only speculate as to the explanation of their pain, feeling assured that it is not of coronary origin. Many of them are suffering from a cardiac anxiety state. There is an interesting, and sometimes a diagnostically difficult, group of patients, usually women, who suffer from severe paroxysms of precordial, usually not sternal, pain, which may radiate into the arms, back, or jaws. These paroxysms may be provoked by emotion, or there may be no obvious exciting cause. They come after rather than during effort, and they are usually widely spaced, with periods of robust health without limitation of physical effort between them. The subjects of these attacks, though sometimes temperamental, are often quite stable psychologically. Their symptoms are very real and severe, and may indeed be quite alarming. Possibly these paroxysms may be due to spasm of the oesophagus or the cardiac sphincter. X-ray confirmation of this is obviously difficult to obtain, though I understand that William Evans has made some interesting kymographic observations on this class of case. Diagnosis is made more difficult here by the fact that nitroglycerin gives relief; but perhaps it does so by relaxing gastric or oesophageal and not coronary spasm.

I submit that in the differential diagnosis between true angina and these non-coronary pains careful history-taking is even more important than physical, including instrumental, examination, and that the characteristic and constant relationship between anginal pain and effort is fundamental.

Personal Statistics

Turning now to my own statistics, out of 1,000 cases 779 were males and 221 females, giving a female/male ratio of 1:3.5, which seems to be about the usual ratio found in the literature, though in a recent report from the Mayo Clinic on 3,440 anginal patients the female/male ratio was 1:4.3. This far heavier incidence of angina in males than in females has never, so far as I know, received a satisfactory explanation. In the past no doubt women led a more sheltered life. But certainly to-day no one would contend that men work four times as hard as women; in fact, some might argue that the reverse is true. I have not been able to satisfy myself that the incidence of angina in women has increased of recent years as compared with that in males. If smoking plays an important part in the causation of coronary disease, which I doubt, we should certainly expect a more equal sex incidence during the next ten years or so.

Nor is there any satisfactory explanation of the unquestionably heavier incidence of coronary disease in the non-hospital as opposed to the hospital population.

As to age incidence, my figures are much the same as those of the Mayo Clinic:

	Under 30	30-40	40-50	50-60	60-70	70-80	80--
Females ..	0	1.3%	11.7%	29%	39%	15%	4%
Males ..	0.25%	3.2%	14.6%	33.9%	36%	11.1%	1%

Approximately 70% of all these patients were aged between 50 and 70 at the onset: 58% of women and 48% of men were

over 60 at onset, which confirms the general impression that coronary disease tends to become manifest at a later age in women than in men. In 26 males the age at onset was under 40, in 2 under 30, the youngest being 26. There were only 3 women under 40 and none under 30.

It has become evident that coronary disease in young subjects is not so rare as used to be thought. During the recent war French and Dock have reported 80 cases of coronary disease in American soldiers aged 20 to 36, and Newman 50 cases of coronary occlusion occurring in Service men and women in this country aged 35 or less: 22 of Newman's patients were under 30, the youngest aged 20. At necropsy atheromatous changes were found, in several instances accompanied by extensive calcification. Stolkind reported four personal cases of angina in children, and collected a further 25 cases from the literature. Many of these cases occurred in rheumatic children, and in some the evidence of angina was not very convincing.

Aetiological Factors

Family history plays a notorious part in the aetiology of cardiovascular disease, and it did so in almost exactly half my cases. But this leaves another 50% of patients whose coronary disease cannot be attributed to inheritance.

Stress, mental or physical, is often thought to be responsible for early cardiovascular death, and coronary disease has been brought into the ever-increasing ambit of psychosomatic disease. But do people really work harder or live more strenuous lives than their grandfathers did? I sometimes doubt it. Certainly we eat and drink much less than they did. I have looked carefully through the histories of my patients, and in only 20% of them do I find evidence of subjection to outstanding stresses. Many of them in fact seem to have lived remarkably placid and sheltered lives. Dr. Paul White of Boston, on a recent visit to this country, told us that in the first edition of his book *Diseases of the Heart* a sentence emphasizing the relationship between angina and stress was in italics, in the second edition in ordinary print, and in the third deleted! Nor am I familiar with the "coronary disease personality," as described, at some length, by Arlow.

Tobacco has long been thought to be a factor in the causation of arterial spasm, and there seems to be convincing experimental evidence of this. Numerous workers have demonstrated that the smoking of two cigarettes usually lowers the peripheral skin temperature, diminishes the peripheral blood flow, and raises the systolic, and still more the diastolic, blood pressure. It is said that these changes may occur not only during the smoking of the cigarettes but sometimes for as long as 30 minutes subsequently. This is depressing information to the smoker, but he will be encouraged to hear from Goetz that very similar results are obtained if the subject is alarmed, or asked to do a difficult sum, or even to take a series of deep breaths. Goetz concludes that the driving of a car in traffic would produce more adverse circulatory effects than the smoking of several cigarettes in an armchair at the club!

I always advise sufferers from intermittent claudication to stop smoking, usually without any amelioration of their symptoms. But very occasionally the results are dramatic, and I have seen relapse occur if smoking is resumed. So far as so-called "tobacco angina" is concerned, I have never encountered such a condition, and certainly I have never seen angina cured by stopping smoking. Statistically 17.6% of my coronary patients were non-smokers, 42.6% smoked moderately—i.e., not more than 20 cigarettes a day—39.8% were heavy smokers. As a control I investigated the smoking habits of a small series of non-cardiac cases, and found much the same figures.

Coronary disease persisted for more than twenty years in 11 of my patients, for more than thirty years in 2 of them. The record duration was fifty-two years, in the case of a lady who had her first attack of angina at the age of 30; she was leading quite a busy life at the age of 80, though still liable to angina whenever she walked. She died suddenly at the age of 82.

It has long been known that quite extensive coronary disease is compatible with an active life, and need not necessarily be associated with angina. In fact, this used to be put forward as an argument against the view that angina is due to coronary ischaemia. Coronary occlusion often antedates angina. It did so in 225—i.e., 22.5%—of my cases. Yet before coronary

occlusion can occur there must almost always be coronary disease. Moreover, a remarkably complete functional recovery is possible after a coronary occlusion. One of my patients played vigorous games after a coronary occlusion at the age of 39. He had a second attack at the age of 48, and, against advice, was playing tennis regularly two years later, without any angina. Now at the age of 58 he is at work, plays golf, and mows his lawn without cardiac symptoms.

It is quite common for coronary disease to be entirely latent till sudden death occurs. Prof. Hume of Newcastle tells me that since 1911 he has performed or attended post-mortem examinations on 160 miners who had died suddenly and unexpectedly in the pit or in close proximity to it. The cause of death in each instance was coronary atheroma, and the majority of the men had been working regularly, without complaint, up to the moment of their fatal collapse. Only 40 had premonitory symptoms. In one case there was a clear history of an attack of coronary thrombosis two years previously, after which he had resumed his normal work in the mine and continued it till his sudden death. In approximately 50% of the 160 cases there were old fibrotic scars in the heart muscle.

The explanation of coronary disease without symptoms is presumably that a wonderfully efficient collateral circulation may be formed if arterial obstruction develops sufficiently slowly. As Lowe and Wartman point out, "complete obstruction may, gradually produced, effect no disturbance whatever in the blood supply to the tissue. On the other hand, should the parent vessel supplying the anastomotic circulation become suddenly blocked, the area deprived of blood supply will be much greater than that following blockage of a similar vessel in a normal circulation." Hence, presumably, the sudden fatal attacks in Hume's coal-miners with previously symptomless fibrotic hearts. In this way, too, we find an explanation for the fact that, on the whole, angina in those over 70 runs a more benign course than it does in those under 60.

Relation between Hypertension and Coronary Disease

Investigating this relationship, I classified my cases as having a normal blood pressure where the readings were below 160/100, moderate hypertension those above these figures but below 200/120, gross hypertension where these last figures were exceeded. Throughout the entire series, in 44.6% the pressure was normal, in 33.7% moderately increased, and in 21.7% grossly increased. Excluding those cases in which an existing or recent coronary occlusion was thought to be responsible for a low blood pressure, the figures were: normal tension 30.6%, moderate hypertension 42.3%, gross hypertension 27.1%. So that nearly 70% of my anginal patients without coincident or recent coronary occlusion were hypertensives. These findings surprised me, for I had not realized that the proportion of hypertensives was so high. In a recent paper Fisher and Zukerman say that in the literature hypertension antedating coronary occlusion has varied between 33 and 73%. Of their own 108 cases of coronary occlusion, hypertension antedated the occlusion in 65% of the women and 39% of the men. They point out that though negroes are more prone to hypertension than whites, they show a significantly lower incidence of coronary disease. Nevertheless, one cannot help suspecting that there may be some aetiological factor in common between hypertension and coronary disease. But, unhappily, in spite of all the intensive investigation of hypertension during the last decade, fruitful though it has been, we are still abysmally ignorant of its aetiology: in the words of Harvey, "All we know is infinitely less than all that still remains unknown."

The London County Council allows the staff of its public health and social welfare departments to have free medical treatment at its general hospitals, but not at its mental hospitals. The reason for this restriction is the long-term nature of institutional care associated with mental illness. It is considered, however, that this does not apply to many types of nervous disorder which are in particular dealt with at the Maudsley Hospital, and therefore free treatment is now to be provided there, subject to review in individual cases, as at the general hospitals, when recovery is not affected in twelve months.

DEFICIENCY NEUROPATHIES OBSERVED IN MADRID DURING THE CIVIL WAR (1936-9)*

BY

M. PERAITA, M.D.

Manicomio Nacional de Santa Isabel, Leganés

Among the 3,116 patients suffering from deficiency diseases studied at the Institute of Nutritional Hygiene in Madrid during the Spanish Civil War we selected 98 cases with serious nervous disorders, as we were greatly impressed with their not showing the slightest signs of any skin symptoms connected with pellagra.

"Painful-feet" Syndrome

The most frequent symptoms in these cases were typical acro-paesthesias occurring mostly in the toes, but also appearing in many cases in the finger tips (patients complained "pins and needles"; "as though I had ants under my nails"). Generally, together with these acro-paesthesias there appeared some much more alarming phenomena—patients complaining of "terrible prickings" and "horrible stabbing pains" in the hands and feet or in other parts of the limbs (calves, thighs and forearms). Sometimes after the appearance of these symptoms or coincidentally there arose what, owing to its close resemblance to the causalgia described by Weir Mitchell, Morchouse, and Keen in wounds of the peripheral nerves, have called *causalgic symptoms*. Some of the more intelligent or self-observing patients began to notice that their feet became peculiarly sensitive to heat and unable to bear it, soon as their feet were placed near a stove they began to complain of "pains, and a very troublesome feeling of discomfort." I found that when night came, and especially when in bed, the feet, which during the day had mostly been "insensible, cold as ice," began to feel "very hot like fire." They go on to feel as though their feet were on hot coals, and to experience an atrocious sensation of burning which obliged them to move their feet out of the bed and let the cool air of the room to them, to walk barefoot on the floor, or to wrap their feet in cloths wrung out of cold water. At the height of their illness the patients presented a special sensitiveness of the skin of affected parts, so that in addition they could not bear the slightest touch on them. But patients also complained of acute sensation of cold in the extremities often alternating with these causalgic sensations ("my feet and legs are cold," "my feet are like ice"). Often this sensation of cold became painful, and they spoke of "cold pains inside the feet." Some described the succession of these phenomena very graphically ("I feel as you do when you put your hands into snow; first I feel very cold about the feet, and then they become warmer and warmer, until I can't bear the heat of them any more, and they burn me").

Other Symptoms

These signs of "painful feet" were predominant, but all of the following, discussed in greater detail by Peraita and Grande (1941), were observed in this series: adynamia, depression, lacrimation, insomnia, forgetfulness, reduced acuity of special senses, perianal erythema, hair and nail loss, girdle sensations, amenorrhoea, impotence, polyuria, changes in mucous membranes and in the motor functions of the gastro-intestinal tract, micturition, and sweat regulation. It was interesting to contrast the rarity of peripheral motor defects and cardiac and skin lesions with the frequency of both cutaneous and proprioceptive sensory changes. Little classical pellagra was observed but no beriberi, and while neither purified vitamin B nor nicotinic acid was effectively curative of the nervous lesions success was obtained with 90 g. dry yeast daily by mouth.

HOSPITAL SURVEY

NEWCASTLE AND THE NORTH-EAST

he latest volume of the Hospital Survey of England and Wales* covers the north-eastern counties, Northumberland, Durham, and part of North Riding—an area roughly coterminous with the influence of the Newcastle School of Medicine. The surveyors were Sir Hugh Lett, now President of the British Medical Association, and Dr. A. E. Quine, of the Ministry of Health.

These Surveyors consider that the area forms a natural medical province, and propose its division into five districts based on Newcastle, Sunderland, Middlesbrough, Darlington, and Durham, in each of which districts there could be a full range of hospital facilities, with the possible exception of a very few highly specialized subjects, all the hospitals in each district forming a combined service. They are of the opinion that the Hartlepoons should combine for hospital purposes with Sunderland or Middlesbrough, and that Gateshead, Tynemouth, and South Shields should come in with Newcastle.

A dearth of consultants is noticed in this hospital region, particularly in obstetrics and gynaecology, paediatrics, dermatology, nervous diseases, and psychiatry. In medicine, outside Newcastle, there are only two physicians whose practice is purely consultative—one in Sunderland and the other in Middlesbrough. The financial aspect calls for consideration, for there is not enough private practice in the area to support a large addition to the number. The Surveyors suggest that all recognized consultants engaged in the future hospital service should be offered payment on a part-time or whole-time basis.

Medical Centre at Newcastle

Newcastle has a first-class teaching hospital in the Royal Victoria Infirmary, the centre of medicine in the north-east, and with the prospect of close association with special hospitals in the city and the development of large special departments in the municipal general hospital Newcastle should take an even higher place as a medical centre than in the past. The proposed construction of a Hospitals Centre at Newcastle, which would include the infirmary and six special hospitals on one site, is regarded as a plan worthy of all encouragement. These hospitals together would provide about 900 beds, but to make them as they stand would result in an ill-balanced aggregate. The Surveyors consider that it would be better to forecast a Hospitals Centre of 1,250 beds, with provision for immediate extension by 250 if this seems advisable when the buildings are nearing completion. This would provide for a large number of acute sick from the Newcastle district and at the same time would be adequate to meet the needs of the medical school and of a consultative centre.

Other Parts of the Region

In the Darlington district there is a single hospital—the Darlington Memorial—modern and well built, which could be developed as a district hospital. In the other three centres—Sunderland, Middlesbrough, and Durham—it is recommended that certain hospitals should join together and by close co-ordination of their work form a united district hospital of at least 600 beds (except Durham, which could hardly sustain that number), staffed by consultants whose work could not be confined to in-patients but should include regular attendance in the out-patient department, charge of beds at associated hospitals, and visits to cottage hospitals.

At Sunderland a united general hospital of 800 beds is recommended, to be provided by the reconstruction of the Royal Infirmary, by additions to the children's hospital, and by the enlargement of the Monkwearmouth. The municipal hospital, already partly modernized, should proceed with its plan of reconstruction and enlargement, with such modifications as may be made after discussion with the United Voluntary General

Hospital. At Middlesbrough it is not thought that any of the existing hospitals are suitable for the extension and enlargement required to give the necessary services of a large general hospital for the district, and it is recommended that a new hospital be built to replace North Ormesby Hospital and the North Riding Infirmary. At Durham, as an interim measure, every effort should be made to secure Dryburn E.H.S. hutted hospital, and this and the Durham county hospital should form one complete general hospital for the district. As a long-term policy one general hospital should be established in the Hartlepoons, with 350 to 400 beds for the acute sick, and a chronic sick section in addition. It should replace the Cameron, Howbeck, and Hartlepoons hospitals, which in the meantime should pool their resources to form one hospital service with three branches.

Intermediate and Cottage Hospitals

The Surveyors urge that hospitals intermediate in size between district and cottage hospitals, such as the Victoria Jubilee Infirmary at Tynemouth, Ingham Infirmary at South Shields, and the Stockton and Thornaby Hospital, and possibly some of the municipal hospitals, should be in close association with the district hospitals, with the placing of their beds and out-patient departments in charge of consultants drawn from the district hospital's staff. Cottage hospitals, in the Surveyors' view, serve a useful purpose, and in this area the great majority are equal to the demands made upon them. The objections to the performance of operations in these hospitals cannot be very strongly sustained if the operating theatre is well equipped, the nursing good, and the accessory services satisfactory, and if skilled assistance is within easy reach in the event of emergencies. But the primary function of these hospitals should be to provide accommodation for patients who can receive efficient treatment from general practitioners.

Taking the area in general, the number of beds for the chronic sick is adequate, though there are difficulties in some rural areas. It is recommended that consultants from the district hospitals should pay regular visits to the chronic sick wards or hospitals.

"The mass of clinical material that these patients provide offers a wide field for clinical research which, if cultivated, would produce a greater knowledge of the diseases of old age and a better understanding of certain other diseases, especially in their later stages, and so lead to further advances in the treatment of all who may be affected by them."

Accident and Orthopaedic Services

The Surveyors call for an extension of the fracture clinic organizations to cover all injuries. This means raising the status of the accident service of the hospitals by making it a department with a visiting surgeon in charge. First-aid work is reported as excellent, but it is suggested that the first-aid station or team at the factory or pit should be an outpost of the hospital and in close touch with it so that the first-aid may be in conformity with the principles practised at the hospital. A hospital with an accident department should also have a rehabilitation department. The view is taken that the treatment of injuries from the survey area is over-centralized at the Royal Victoria Infirmary, Newcastle, where, so far as teaching is concerned, 50 or 60 beds for fractures and orthopaedic cases would be enough. The Surveyors recommend that two general hospitals, one at Durham and the other in the neighbourhood of Bedlington or Ashington (Northumberland), should treat in their accident departments injuries occurring locally which are at present sent to Newcastle. The accident services of Victoria Jubilee Infirmary, Tynemouth, and Queen Elizabeth Hospital, Gateshead, will no doubt be developed. It is also recommended that the five towns of South Shields, Sunderland, the Hartlepoons, Middlesbrough, and Darlington should each have an accident department, and that in each of the three counties there should be an orthopaedic scheme in which the hospitals and local authorities would combine.

Further sanatorium accommodation will be needed in the area in the near future, and a closer association between the tuberculosis service and the general hospitals is urged.

"Extreme specialization in tuberculosis and its detachment from other diseases of the chest and from general medicine is not without

* Ministry of Health. *Hospital Survey. The Hospital Services of the North-eastern Area*. London: H.M. Stationery Office, 1946. 1s. net.

its dangers. The separation of this prevalent disease from other branches of medicine has become so pronounced that general physicians now have relatively little opportunity of studying it and its treatment, and the time has come when the position should be reviewed."

As for infectious diseases hospitals, the Surveyors recommend as a long-term policy the provision of a few large institutions, each serving a wide area. The smaller hospitals should gradually go out of use. On maternity accommodation the two Surveyors take rather different views. One of them considers that provision might be made in town areas for 40 to 50% of expected births (15-19 beds per 1,000 births), and the other that planning should be on a more generous scale, providing for 60% of expected births, with antenatal beds in the proportion of one to three lying-in beds (30 beds per 1,000 births). They agree that in each hospital district there should be a principal maternity unit with antenatal and postnatal clinics. Maternity homes in the smaller towns and villages, where the atmosphere is homely rather than institutional, meet a definite need, and more of them should be provided.

DELAY IN SUPPLY OF SPECTACLES

The Faculty of Ophthalmologists recently appointed a sub-committee, upon which the manufacturing opticians were represented, to investigate the causes of the delay in the supply of spectacles. The meeting proved informative and useful and the results of its deliberations were considered by the Council of the Faculty on Oct. 11. It is anticipated that in twelve months' time the accumulation of orders which is the cause of the present delay will have been dealt with and deliveries will be back nearly to normal, but it was agreed to publish six suggestions for the consideration of prescribing surgeons and opticians in the meantime. The Council of the Faculty considers that the carrying out of these suggestions would result in an immediate amelioration of the situation and submit them with confidence. The suggestions put forward are as follows:

- 1 Except in cases of genuine medical urgency, avoid priority orders.
- 2 Unless there are good reasons for the contrary, avoid prescribing 1/8 powers, and 1/4 powers over 4D.
- 3 In the lower ranges, covering the "stock powers," prescribe the lenses, except in the case of bifocals, which are more easily obtained in toric form.
- 4 Avoid ordering tinted lenses wherever possible. When ordered, give alternative tints.
- 5 Where possible, indicate on the prescription that a variation of 1/4D up or down is permissible. It is suggested that this should be done by the sign " ± 0.25 " on the prescription.
- 6 Avoid prescribing prisms unless really necessary. All prescriptions including a prism, other than those that can be dispensed by decentration, demand special grinding.

WELFARE OF OLD PEOPLE

During the present century public conscience has been more and more concerned with the living conditions of its old people, a fact which is largely due to the pioneering work of the voluntary social service organizations. With the passing of the National Insurance Act and the promise to reform the Poor Law, much of this work has rightly been transferred to the statutory authorities. But a great deal remains in the voluntary field.

Work of the Voluntary Agencies

In 1943 the London Council of Social Service, realizing that the hardships of war fell heavily on the old people, who despite their amazing fortitude were the least able to put up with them, set up a committee to deal with evacuation problems, home help schemes (before these were introduced by local authorities), special meals services, and a country rest home. During the flying bomb period, when old people were not among the official categories that could be evacuated to billets, a group of voluntary organizations was formed which was able to get large numbers away from the Metropolis.

To-day there are 28 local Old People's Welfare Committees in the London area, their work being co-ordinated by the London Council of Social Service, whose advisory services are always at their disposal. Periodical meetings are arranged for pooling information and recommending common action. The London Council has taken steps to bring together the associations which run resident hostels for the aged. Consultations of this kind are a useful stimulus and help to maintain standards.

Another part of the London Council's work is research. Investigations are just being completed into special housing facilities: old people, the provision of "home helps," and old people's clubs. The results of this research will be made available to both statutory and voluntary bodies concerned with the welfare of old people in Greater London. Not only do they constitute a most useful survey, but also are a means of pooling information and ideas; they reveal a vast amount of voluntary effort on behalf of old people—and by the old folk themselves. There are, for example, in the London area alone over 100 old people's clubs, with a total membership of about 10,000. Their chief object is to provide social activities (from table games to summer outings, or "window boxes to craft work), thus counteracting loneliness, the most distressing feature of old age. Many incorporate welfare services in addition. Old People's Welfare Committees arrange friendly visits to old people in their homes—the simplest and most warmly welcomed form of service. They undertake shopping for old people who find "lining up" too much for them. They arrange special meal services, either in centres where a cheap meal can be bought in pleasant surroundings, or by a mobile canteen service for invalids. They operate clubs and residential hostels.

The London Council of Social Service, which is the principal co-ordinating organization for voluntary bodies in London, has its counterpart elsewhere in the regional offices of the National Council of Social Service, does not regard this work as of emergency character. It is "long term" and necessary to fill the gaps which invariably exist in statutory provision. The Council considers that a crucial test of the quality of a civilization is the way in which it treats its old people, and with the rapidly increasing number of old people in this country it regards this as one of the most important of its many social service activities. Its office is at Bayley Street, Bedford Square, W.C.1.

VICTOR HORSLEY MEMORIAL LECTURE

The Victor Horsley Memorial Fund, which was raised in 1919 to commemorate the services of Sir Victor Horsley to Science and the Empire, is devoted to the giving of a lecture triennially in London entitled the "Victor Horsley Memorial Lecture." The invitation of the Trustees (the Presidents for the time being of the Royal Society, the Royal College of Surgeons of England and the British Medical Association, the senior physician of the National Hospital for the Paralyzed and Epileptic, Queen Square, the senior surgeon of University College Hospital, and Mr. Stanley Robinson, son-in-law of Sir Victor Horsley) the seventh lecture will be delivered by Dr. F. M. R. Walshe, F.R.C.P., F.R.S., physician to the National Hospital, and physician-in-charge, Neurological Department, University College Hospital, in the Lecture Theatre, National Hospital, Queen Square, W.C., on Wednesday, Nov. 27, at 5 p.m. The title of the lecture is "The Contribution of Clinical Study to the Physiology of the Cerebral Motor Cortex," and the chair will be taken by Sir Alfred Webb-Johnson, Bt., P.R.C. Admission to the lecture is free on presentation of visiting card.

The midge in Scotland may not be a carrier of infection but its biting propensities make it a serious source of irritation both to the Scottish people and to many tourists. With this in mind the Secretary of State for Scotland in 1944 asked his Scientific Advisory Committee, whose chairman is Sir Alexander McGregor, to advise whether there were suitable repellents which could be used against midges, and whether there were safe methods of destroying them in their breeding grounds. A subcommittee, with Prof. F. A. E. Croft as chairman, was set up and the services of Dr. Ewen Cameron were secured for controlling the field work. In the first place, a matter of urgency, an empirical investigation into repellents was undertaken in the summer of 1945. An interim report, *Control of Midges* (Edinburgh: H. M. Stationery Office, 2d.) gives an account of the work of the subcommittee, which was able to produce and recommend a formula for a midge repellent, which was made public in good time for the midge season of 1946. The preparation found most effective was dimethyl phthalate (D.M.P.), the repellent used against the mosquito during the war. Tests were also carried out with home-made veils constructed from stout, wide-meshed hospital gauze. When impregnated with D.M.P. they gave complete protection so long as the midge attack lasted; but unimpregnated veils gave no protection whatever.

Reports of Societies

WARTIME RESEARCH IN TROPICAL DISEASES

The annual meeting of the Research Defence Society was held on Oct. 23, Prof. A. V. HILL presiding, when the fifteenth Stephen Paget memorial lecture was delivered by Prof. HAMILTON FAIRLEY on "Wartime Research in Malaria and other Tropical Diseases of Military Significance."

He said that while many of the advances in knowledge of chemotherapeutic control of tropical diseases and chemical control of insect vectors had been obtained from experiments on human volunteers, the fundamental work which placed the new agents at the disposal of medicine was initially made possible only by large-scale animal experiments. New antimalaria drugs had to be tested in the first instance on birds infected with different species of bird malaria, and the toxicity of insecticides such as D.D.T. and dimethyl phthalate on animals. During the early campaigns against the Japanese in 1942-3 casualties from sickness were from five to thirty times as common as battle casualties; malaria and dysentery were as serious a menace as the enemy.

Chemotherapeutic Control of Malaria

Before the war the knowledge of the protection afforded by regular small doses of antimalaria drugs to individuals not previously infected with malaria (non-immunes) was inadequate. Quinine had been extensively used as a suppressant in the first world war, with results which, though useful, were far from satisfactory. In 1943 at a medical research unit at Cairns, Northern Queensland, 850 healthy volunteers were experimentally infected with sporozoite-induced malaria. During the three years of the investigation the drugs studied included quinine, plasmoquine, sulphadiazine, atebtrin (mepacrine), chloroquin, aludrine, and others. It was shown that quinine in certain daily doses was not a satisfactory suppressant in jungle warfare, and that drugs of the sulphadiazine group were not suitable suppressants in New Guinea, as they failed to suppress benign tertian infections. On the other hand, excellent results were obtained in 1943 with Cairns volunteers who had received one tablet (0.1 g.) of atebtrin on every day of the week for four weeks prior to exposure to infection, during the period of exposure, and for 23 days after the last infective bite (New Guinea strains). In volunteers infected with malignant tertian malaria atebtrin was shown to be acting not by preventing infection, but by producing radical cure as a result of the destruction of the young asexual parasites soon after they had gained access to the circulation. It was shown that if troops took atebtrin in adequate daily dosage it was possible for them to go into hyperendemic areas of malaria without significant malaria casualties, while blackwater fever and fatalities would not occur.

Consequent on the establishment of a high standard of atebtrin discipline, malaria rapidly came under control. From December, 1943, the malaria rate in Australian troops in hyperendemic areas had fallen from 740 per 1,000 per annum to 26 per 1,000 per annum in November, 1944; with the exception of one A.I.F. division, this low level was maintained throughout the campaigns of 1945. It required a large-scale experiment on human volunteers to convince medical and combatant officers of the extraordinary efficacy of the atebtrin regimen; had it been possible to infect animals with human species of malarial parasites the schizonticidal action of atebtrin in suppressing and curing malignant tertian and suppressing benign tertian might have been demonstrated much earlier.

New Antimalaria Drugs

In the 4-amino quinoline group of compounds, sontochin and resochin (chloroquin) had proved to be essentially schizonticidal in action; they did not discolour the skin, and they yielded therapeutic results comparable with atebtrin. Although effective suppressants, neither was a causal prophylactic. Plasmoquine in large doses acted as a complete causal prophylactic in *P. falciparum* infection, and a partial causal prophylactic in *P. vivax* malaria, but it was too toxic for routine use as a suppressive drug.

Paludrine was shown to be a complete causal prophylactic against malignant tertian infections and a partial one against

benign tertian infections in a dosage of 100 mg. daily. Later it was found that a single dose of 100 mg. given 39-120 hours after heavy infection with *P. falciparum* entirely eradicated the infection before there was time for asexual parasites to appear in the blood. The possibilities of a bi-weekly or even a single dose regimen of paludrine applied to native villages and epidemics in hyperendemic areas opened up an entirely new field in the chemotherapeutic control of this disease, not only because of the schizonticidal effects of the drug, but also because of its extreme potency as a causal prophylactic in single doses of 100 mg. given on the 2nd-6th day following infection.

Other Tropical Diseases

Prof. Fairley briefly reviewed the measures found necessary for the control of "jungle dengue." In Northern Queensland dengue was a disease of towns, being transmitted by the domestic mosquito *Aedes aegypti*. In New Guinea, however, it affected large numbers of troops living in the jungle in the absence of this mosquito vector. Lieut-Col. I. Mackerras and his associates fed four species of mosquitoes on dengue patients in New Guinea and sent them 2,000 miles by plane to Sydney, where they were re-fed on human volunteers. By this means it was discovered that a new vector, *Aedes scutellaris*, was transmitting dengue in New Guinea. The bionomics of this mosquito were carefully studied, and once its habits and breeding places were ascertained rational control measures were instituted. During outbreaks these measures were found to decrease markedly the number of troops affected, and the dengue rate never again reached epidemic proportions in the south-west Pacific.

Carefully controlled clinical and bacteriological investigations in 1941 in the Middle East confirmed the expectations of Marshall that sulphaguanidine would prove a specific cure for bacillary dysentery. Later in New Guinea it was shown that the immediate administration of this drug in full dosage at the onset of diarrhoea aborted the disease under field conditions and eliminated carriers. In 1942 an epidemic of dysentery affected Australian troops fighting over the Owen Stanley ranges. The fate of Moresby lay in the balance. Sulphaguanidine was rushed up by plane to New Guinea and into the forward areas, and the epidemic was controlled within 10 days. In jungle fighting efficient sanitation was frequently impossible, and both in New Guinea and Burma the incidence of diarrhoeal diseases was reduced to an unprecedented low level by the use of this drug in the forward areas. It had the great advantage of not causing renal complications or agranulocytosis, and for this reason could be distributed without medical supervision.

Scrub Typhus

Scrub typhus was a serious disease both in the Pacific and south-east Asia because of its high mortality rate, which approximated to 8%. Two possible measures for its control were developed during the war: (1) the widespread use of dimethyl or dibutyl phthalate as a larval miticide applied to clothing, and (2) inoculation of troops with scrub typhus vaccine prepared from cotton rats. Vaccination was being tested in Burma on a large scale, but hostilities ceased before any definite conclusions could be reached as to its value. On the other hand, definite evidence had been obtained by Major MacCulloch as early as 1943 that dibutyl phthalate rubbed into the clothing by hand would give complete protection to volunteers spending many hours of the day in mite-infested jungles in New Guinea. Though no more effective than dimethyl phthalate as a miticide, it was found to be better retained in clothing, standing up to seven washings. The subsequent widespread use of these anti-mite fluids led to a great reduction in the incidence of typhus in troops operating in the Pacific and south-east Asia.

Finally the lecturer referred to the great value of the new synthetic insecticide, dichlor diphenyl trichlorethane (D.D.T.). During the war D.D.T. had proved of the greatest value in terminating the typhus epidemic in Naples and in the control of both malaria and bacillary dysentery. The final control of many insect-borne diseases had been brought appreciably nearer by the discovery of the astounding insecticidal action of D.D.T. by Müller in the Geigy laboratories at Basle, and by the work of British and American entomologists and toxicologists.

MEDICAL MYCOLOGY

One of a series of meetings in connexion with the jubilee of the British Mycological Society was held at the Royal Institution on Oct. 23, when addresses were given on various aspects of the medical study of fungi. Sir ALEXANDER FLEMING presided.

Dr. C. W. EMMONS, who brought the greetings of the Mycological Society of America, gave the first address, on fungi which caused human disease—a group which was much neglected. Fungous diseases ranged from superficial irritations to deep-seated and systemic fatal mycoses. Medical mycology was not new. Aetiological relationships between fungi and human disease had been known for more than 100 years. In 1839 Schoenlein described the fungus which caused favus, and Lagenbeck the fungus which caused thrush, but very little medical mycological work was attempted. During the last fifty years valuable opportunities had been lost from failure to study more systematically those fungi which caused human disease. The trained mycologist should collaborate with the clinician. Neglect of this field was probably related in part to the phenomenal impetus given to bacteriology by Pasteur, Lister, and Koch, to the fact that the bacterial diseases of man were more common than those caused by fungi, and to the lack of contact between the mycologist and the hospital diagnostic laboratory. The mycoses, with few exceptions, were relatively unknown to medicine. There was now, however, an increasing tendency to recognize fungi among the causes of disease.

In the United States in 1942 out of 1½ million deaths only 359 were attributed to fungi, but in the registration area this was nearly twice as many as the deaths due to paratyphoid fever, undulant fever, smallpox, rabies, leprosy, plague, cholera, yellow fever, and relapsing fever put together.

The Mycoses as a Group

Some of the mycoses, particularly the superficial ones, were not fatal although common, and there were mild forms of some of the generally fatal diseases, so that the true incidence of the mycoses was not known. Coccidioidomycosis, for example, a mycosis once thought to be invariably fatal, was now known to be mild and self-limited in most cases. There was reason to suppose that histoplasmosis also had a mild unrecognized form, but the evidence rested upon analogy and upon a dubious skin test known not to be specific. Since its discovery and description in 1906 by Darling histoplasmosis had appeared rarely and sporadically throughout the world, until up to the present time about 100 cases had been observed, the majority in the eastern part of the United States, and almost all fatal. But the wide occurrence of skin sensitivity to histoplasmin had been interpreted by some investigators as evidence in support of the existence of a mild form of the disease. Histoplasmin was a sterile filtrate of a synthetic broth culture which was injected intradermally, and, in a sensitized individual, produced within 48 hours a localized area of oedema resembling a positive tuberculin test. Such a reaction occurred in laboratory animals infected with experimental histoplasmosis, and in many people who were not ill and had no history of an illness resembling histoplasmosis. The percentage of the general population reacting to histoplasmin varied in different geographical areas. The subject was of great interest because it might offer an explanation of the occurrence of calcified lesions in the lung in persons who apparently had never had tuberculosis. It had been suggested that there was a benign form of histoplasmosis which gave rise to lesions which healed and became calcified.

Some of the superficial fungous infections such as dermatophytosis and secondary moniliasis were extremely common and annoying. The mycoses as a group were more fatal than some important bacterial diseases, and some were more frequent in mild forms than their recognition indicated.

Diagnosis of Mycotic Infections

The diagnosis of mycotic infections, Dr. Emmons continued, rested largely upon the laboratory. Even the superficial skin lesions caused by ringworm fungi might resemble so closely certain dermatoses due to skin irritants or sensitizing chemicals that a demonstration of the fungus in epidermal scales on

microscopic examination or its isolation in culture was necessary in order to make a differential diagnosis. In systemic mycosis the demonstration of the fungus microscopically or by culture was even more important in establishing the diagnosis. Fortunately in dermatophytosis the epidermal scales or infected hair stubs were plentiful and easily obtained, and the laboratory procedures were reasonably effective. Epidermal scale were readily cleared by warming in a drop of 1% sodium hydroxide on a microscope slide. Many media were suitable for the cultivation of pathogenic fungi, but some modification of Sabouraud's agar was commonly used.

The deeper mycoses required slightly different processes. *Sporotrichum* was easily isolated from the subcutaneous abscesses of sporotrichosis by withdrawing pus from a unopened and therefore uncontaminated abscess and spreading it upon agar. *Histoplasma* could be isolated from the circulating blood or from the sternal bone marrow. *Cryptococcus* could be obtained in pure culture from the spinal fluid in cases of meningitis. In pulmonary mycosis, and in case with ulcerative skin and mucous membrane lesions, where secondary bacterial contamination was sure to occur, bacteriological methods of spread and taking pure cultures could be used. Differential media were of assistance. Serological methods of diagnosis, so useful in bacterial diseases, were not commonly used in the mycoses.

The production of antibodies by fungi seemed to be erratic. In American blastomycosis, or Gilchrist's disease, for example Martin had reported that in some proved cases antibodies were not demonstrable. In coccidioidomycosis Smith had observed that the complement fixation titre rose as the disease progressed from the acute respiratory phase to the chronic disseminated granulomatous phase.

Distribution of Parasitic Fungi

Trichophyton rubrum was more prevalent in tropical and subtropical areas than in southern zones. Actinomycosis caused by the anaerobe *Actinomyces bovis*, occurred throughout the world. Sporotrichosis, caused by the single species *Sporotrichum schenckii*, had been reported from the gold mines of South Africa to the plant nurseries of the northern United States. Histoplasmosis was caused by a single species of world wide distribution. In some cases a mycosis appeared to have become naturalized in a new area after its accidental importation. Thus the striking dermatophytosis known as *trichophyton imbricatum*, which was native to certain South Pacific areas, was brought to Central America, probably during slavery days, and now grew in localities there. During a visit to Guatemala I saw classical examples, with partially adherent epidermal scales forming concentric and confluent patterns over the entire body surface.

A few mycoses were restricted in distribution. Coccidioidomycosis was endemic in the arid south-west of the United States and in a similar area in Argentina. North American blastomycosis was a peculiar North American disease, more often seen in the States, though it occurred also in Canada. South American blastomycosis was primarily a Brazilian mycosis, though it occurred in other South American countries. Until more was known about the reservoirs of these diseases and the habitat of the fungi causing them it would be hard to explain these geographical limitations in distribution.

As for nomenclature, there had probably been more invalid names than usual selected, as well as an enormous number of transfers from genus to genus. Many fungi had been repeatedly renamed by investigators ignorant of the earlier literature, and there had been too many exponents of the policy of splitting species on the basis of a slight difference between strains. The variability of fungi was a fascinating subject.

Considered from the point of view of the natural habitat of pathogenic fungi they might be divided into two classes: fungi normally associated with man, and fungi which were within his environment and became pathogenic only by chance. The fungi which were pathogenic to man had well-defined morphological characteristics. By far the commonest was that which caused dermatophytosis; it was easily demonstrated in epidermal scales. In mentioning *Actinomyces bovis* he said that contrary to the often repeated statements that actinomycosis was contracted by chewing straws, the agent had not been isolated from any source other than the human or animal body.

Work on Penicillin

Dr. J. H. BIRKINSHAW, of the London School of Hygiene and Tropical Medicine, followed with an address on recent work on products derived from fungi. British manufacturers, owing to the war, had at first been unable to devote sufficient attention to penicillin production, but the American chemical industry had stepped into the breach. The methods worked out by the Americans had become available to British industrialists. Perhaps the most radical advance was the change from surface culture to submerged culture. The submerged method resulted in a great saving of plant space and of labour and offered fewer chances of contamination. Selection of the most active strain of the mould had received careful attention, particularly since the best strain for surface work was found to be the best for submerged cultivation.

The chemical constitution of penicillin had at last been solved. Certain of the rearrangements which the molecule underwent were very unusual and could scarcely have been deduced from the ordinary reactions of organic chemistry. A minute amount of the pure crystalline sodium salt of penicillin 2 had now been synthesized. Penicillin was produced cheaply by the biological method, however, that chemical synthesis had become more a matter of academic than of commercial importance. Penicillins 1, 2, and 4 did not appear to lend themselves to modification, but penicillin 3 might be so modified as to make it possible to obtain an active derivative. It was synthetic in nature, which would be less rapidly excreted than the wholly natural product.

What was the cause of the long delay between Fleming's original observation and the development of the commercial production of penicillin? It was due to the fact that a further partner was necessary in the research team. The mycologist and biochemist could not determine the therapeutic applications of a fungus product without help from their medical colleagues.

Other Antibiotics

The most promising of the new antibiotics was streptomycin, which had very low toxicity. It had now been obtained in crystalline form. It was too soon yet to say what its value was in tuberculosis, but it seemed to hold out great promise. Among other substances to the structure of which he drew attention was expansin. During the war some Dutch clinicians claimed an expansion a modest success in the treatment of mycotic disease of the skin. There were between twenty and thirty antibiotic products of fungi so far isolated in crystalline form. Lavacidin, a fifth penicillin, had a different group in the side-chain; and notatin, an enzyme, was a very potent antibiotic. Although most of the products were antibacterial some were antifungal as well.

Was any advance on penicillin and streptomycin to be expected? Both required complex organic nutrients in the medium for high yields. This was not of much consequence in the case of penicillin, where the adjuvant was a cheap waste product; it was more important in the case of streptomycin. But the addition of such substances was a confession of ignorance, and the task of identifying them must be undertaken.

Disadvantages of Antibiotics

A potential danger was the development of drug-resistant strains of bacteria. The danger might be minimized by using large doses, but could be eliminated only by ridding the changes in the antibiotics employed. Allergic reactions also were not unknown. Another minor disadvantage of penicillin was that it was a mixture of sodium salts of at least four components. Those proportions varied with the strain and method of culture. In two batches of penicillin of equal potency as standardized against a particular organism, say *Staph. aureus*, the activity against other organisms might differ. The chemotherapeutic efficacy, which depended not only on the activity *in vitro* but on a number of other factors, did vary widely. Thus penicillin 4, owing to its rapid destruction in the body, was probably only from about one-sixth to one-tenth as effective as penicillin 2.* It might ultimately be possible to select the most effective form from the chemotherapeutic range.

* From recent American evidence it appears that penicillin 4 has greater therapeutic efficacy than is here attributed to it.

CLINICAL DISCUSSIONS

A clinical meeting of the L.C.C. Medical Society was held at Dulwich Hospital on Oct. 3, when cases were shown by the staffs of Dulwich and St. Olave's Hospitals. 110 members were present.

Dr. LAWRENCE opened a discussion on two cases of hepatosplenomegaly with ascites and asked for suggestions as to the diagnosis and treatment of the ascites, particularly in one of the patients, aged 31, who required paracentesis of the abdomen every 7 to 10 days. There was fairly general agreement that the results of the Talma-Morison operation were disappointing, but an anastomosis between the portal vein and the inferior vena cava (Eck fistula) might be worth trying. Mr. J. L. STEPHEN showed two cases of gastric polyposis and stressed the importance of gastroscopy in diagnosis.

Dr. E. T. BASSADONE opened a discussion on the treatment of pulmonary infarction, which, especially in post-operative cases, frequently preceded a massive pulmonary embolus. He asked for advice on ligation of veins, usually of the leg, from which the embolus spread. Mr. LEWYS-LLOYD advised against tying the common femoral vein, which usually left a swollen, painful leg, and pointed out that there was uncertainty from which leg the warning embolus had come. He advocated early post-operative exercises and the use of intravenous heparin. Mr. G. F. STEBBING pointed out that the majority of cases of pulmonary embolus came from veins giving no symptoms, and that by the time one could definitely suspect the vein of being thrombosed there was probably little danger of the thrombus moving. Dr. B. GOTTLIEB had treated two cases of venous thrombosis with heparin and was not impressed with the results, and thought it would be better as a prophylactic. Dr. B. BARLING pointed out that a venous thrombosis usually started in the calf and the first sign was a rise in temperature, and suggested that instead of looking to the chest to provide the cause of the pyrexia it might be better to examine the legs.

CURARE IN ANAESTHESIA

The Anaesthetics Committee, jointly appointed by the Medical Research Council and the Royal Society of Medicine, is considering the standardization of curare. There are on the market at present two preparations for use in anaesthesia, one amorphous and one crystalline, but both depend for their activity on *d*-tubocurarine chloride. The co-existence of preparations of different potency is a source of danger and may result in serious accidents. The amorphous preparation "Intocosturin" has in fact about one-quarter the activity of the pure crystalline material.

There is also some evidence of wide difference in the reactions of the patient, depending to some extent on the state of health of the individual at the time. The Committee therefore consider it advisable in the present state of knowledge to base the dose on the individual reaction to an initial small injection rather than on any dose/weight ratio. In the average healthy adult this initial dose could be 10-15 mg. of crystalline *d*-tubocurarine chloride or 40-60 mg. of "Intocosturin."

CONTACT LENS SOCIETY

A new society, purely scientific in object and organization, has been formed for the study of contact lens work in all its aspects. Members may be medical or non-medical, and it is hoped to stimulate interest in the subject among optical workers, doctors, physiologists, and others whose domain touches the question at any point. The secretaries, Mr. A. G. Cross and Mr. G. H. Giles, will be glad to supply information and forms of application for membership on receipt of a request addressed to 65, Brook Street, London, W.1. The first scientific meeting will be held on Jan. 20, at 5.30 p.m., at the headquarters of the British Optical Association, 65, Brook Street. Thereafter it is hoped to hold scientific meetings four times a year, or more often if sufficient material is forthcoming. Membership requires nomination by three members of the Council. The officers of the Society are: President, Prof. Ida Mann; vice-presidents, Mr. F. A. Williamson-Noble and Mr. K. Clifford Hall; joint secretaries, Mr. A. G. Cross and Mr. G. H. Giles; treasurer, Mr. C. H. Keeler. Other members of the Council are: Messrs. J. H. Doggart, G. B. Ebbage, F. A. Juler, Sir Stewart Duke-Elder, Messrs. F. Dickinson, H. B. Marton, G. D. McKellen, and T. Hamblin.

Correspondence

The Plebiscite

SIR,—I have read Dr. Alfred Cox's letter (Nov. 9, p. 707) with interest, especially the last paragraph. Aged 46 now, my recollections of the 1911-12 fight are not very clear, but my impressions are not those of defeat. To give one instance, we gained something in the way of regular consulting hours. Since then our Association has gained much experience in dealing with politicians. The recent "show down" over fees is a good augury for the future. In putting our case for another fight to those who doubt our ability to carry it off, it would be helpful to have a true short history of the events of 1911-13. What points were gained and what were lost? Can Dr. Cox or can you, Sir, supply this? I ask this because I believe that, apart from inadequate remuneration, N.H.I. has been a success. Much of the criticism one hears to-day appears to be unjust and ungracious, and some of it sheer nonsense.

As Dr. Cox points out, the new Act contains one feature at least which is unnecessary and repugnant to most of us. Whether we are "ripe" or not, many of us do not want to be plucked at any price. Sixty-six millions of public money might much more profitably be spent in filling in the gaps in our Health Services where these exist. The training of more nurses in the care of tuberculous patients and deprived children are two glaring examples which would suggest themselves immediately to the unbiased. There must be many others. An initial salary is quite compatible with the sale and purchase of practices (see Spens Report, p. 9). The Association might quite well set up a system of arbitration where the true value of a practice is in dispute. It is a pity that the Minister of Health should be a "managing director controlling all the shares." Mr. Bevan's investing interests are prompted by greed for power. Our individual "vested interests" mean just that small share of power which is freedom and true democracy.

I am, etc.,

R. W. L. PEARSON.

SIR,—The Council has decided, quite rightly, not to advise members how to vote in the plebiscite. Therefore it is as well to be a member of Council that I should be able to draw attention to an obvious and important point. All members of the profession remember what was said at the Annual Panel Conference merely threatening asking for resignations, and, fortified by that, they said "No" to the plebiscite, there will be by the time the new Act under which all would be glad to serve, freedom is guaranteed, and of which the public would be proud.—I am, etc.,

H. M. GOLDING.

G. Scoular (Nov. 9, p. 707) raises a point about the plebiscite which must have occurred to many members of the profession. The question "whether negotiations with the Minister of Health" may lead many reasonable doctors to answer in the affirmative. Such an answer, in these cases, will merely indicate their desire to learn the proposed terms of service before deciding whether they will join the Service or not.

As yet they do not know the minimum and maximum number of patients they may have to attend, the radius beyond which they will not agree to visit patients, the possibility of obtaining a better basic salary, the capitation fee, the age at which they may retire, the arrangements for off-duty time, and so on. It does seem reasonable to seek information on such points before answering the plebiscite question in the affirmative. Such an answer cannot be interpreted as expressing ultimate willingness to join the Service.

Secondly, if the majority of the profession answer in the negative, the B.M.A. will still be impelled to negotiate with the Minister of Health for the sake of those members who do intend to serve as National Health Service doctors.—I am, etc.,

London, N.22

A. J. M. BUTTER.

SIR,—The profession should be grateful to Dr. Alfred Cox (Nov. 9, p. 707) for his letter of advice to the profession this new plebiscite. Is to-day the twilight of our freedom. In the *Sunday Times* of Nov. 10 I see that the Lord Chancellor is quite clear about the attitude of the legal profession on question of their freedom. "We of the legal profession have in the past asserted our freedom and independence from interference of the Crown. To-day we are prepared to assert our freedom and independence from the Executive."

The question for our medical profession is, Are we prepared to take the advice of the Lord Chancellor to the legal profession and assert our freedom from the Executive? I am, etc.,

Horsham.

SYDNEY GORDON TIPPETT

SIR,—It seems to me that a far greater political responsibility lies on our profession than many realize. During the war the course of 90 minutes, we handed over all our cherished liberties and freedoms. We have not got them back. The contrary they become constantly fewer and more restrictive. We have now the opportunity of being the first organized body in the kingdom to call a halt to this ill-considered and doctrinaire coercion that passes for policy, and to cause at least one embryo dictator to reconsider his position and the advisability of listening to reason.

I often wonder how long his liberties can be quietly whittled away before the average Briton will explode into resistance. Some such thought I find also in my patients who ask, "Why are you?" or "Why don't you doctors do something about it?" You are in such an unassailable position." Many deeply concerned in the country's affairs are watching us closely and believe, hopefully. They are looking for a lead. I would further and say that in many countries the world over the course of events in our islands is eagerly watched to see how far the British are prepared to be browbeaten by their politicians. In war we doctors are non-combatants. If in peace we are called upon to be the vanguard of the defence for one will feel honoured. For old men who loved it, and young men who have suffered for it need have no hesitation in combining to fight for our reasonable freedom and integrity. After hearing Dr. Dain it is so clear that we have nothing to lose and everything to gain. So let us do it. And let the result be round on the paper: *responsum negativum*.—I am, etc.,

Teignmouth.

JOHN A. TIPPETT

SIR,—I trust that every member will read the letter of Dr. Alfred Cox (Nov. 9) and give it every consideration. It is a able summary of the situation confronting the profession to-day and it refers also to the effect of the present trend of legislation on the general community which is of supreme and urgent importance. We medical men are principally concerned with the art of healing the sick; but when this art has to be subsidized and controlled by the State whereby both patient and doctor become mere pawns in a political game and the liberty of each individual is threatened, all doctors should realize that in opposing the National Health Service Act they are defending the right of every man to shape his own destiny, which surely is his birthright.

Dr. Cox refers to the history of the fight over National Health Insurance in 1911-12 and states that "the present circumstances are not at all comparable." Here I must disagree. We medical men, who opposed that Act, saw in it the forerunner of the present Act and freely broadcast our opinion at the time and for many years afterwards and warned the profession what would eventuate. I do not wish to enlarge upon this; but the whole measure was blindly adopted from Germany, where it was instituted as a purely political measure for the purpose of enslaving the German people. That was not recognized by the Association as it should have been; but now I hope the majority of the Association fully recognize the seriousness of the situation and the effect such a measure will have on the future welfare of our race. The present time is witnessing the destruction of higher values—the tail is wagging the dog—as in the words of *Ecclesiastes* it might be said—"I have seen servants on horseback and princes walking as servants upon the earth."—I am, etc.,

Edinburgh.

FREDERICK PORTER.

SIR,—The National Health Service Bill has received the Royal Assent in the House of Lords; the British Medical Association has circularized every member of the profession, and we now all have the plebiscite forms before us. At last arrived that crucial moment when the profession must decide once and for all whether it will sell its precious freedom, handed down to it by generations of its forebears, for a mess of pottage—and what a mess!

Part B of the report of the Negotiating Committee is, in my humble opinion, admirably compiled and should clearly demonstrate to every general practitioner that once he accepts a Bill as it stands but merely tries to negotiate for better terms of service, etc., he loses not only his own freedom, but a patient's freedom—in other words, he supports the principle of the "closed shop."

Let us all stand firm and refuse to negotiate with any Minister or Government that shows its contempt for the individual and, what is more, for the profession by its relations with the Negotiating Committee in the past. This is our last chance. If we fail here we can never raise up our heads again to a free and honourable profession. We shall be subject to the whims of any future Minister of Health to vary our terms of service and working conditions. We might as well give up all hope and agree to a whole-time service with a 40-hour week and life in a prefab.—I am, etc.,

East Grinstead.

A. C. SOMMERVILLE.

SIR,—May I, as one of the young practitioners to whom the Minister of Health is so anxious "to give security," add one more letter to those already published on the subject of the plebiscite? In my opinion the majority of the men and women entering the profession of medicine to-day (as always) do so not because it is a safe job but because that is where their interest lies. Many letters have appeared in your columns in the past from Service doctors complaining of the petty strictions and loss of personal freedom to which they were subjected, and although this may be necessary to a degree under these circumstances, it must be avoided at all costs in civilian practice.

Thus I consider that the only answer to the question of negotiation with the present Government is "No" if we are to preserve our freedom and that of our patients. As at the moment I am not a free agent, I beg to sign myself

SURGEON LIEUTENANT, R.N.V.R.

SIR,—With the beginning of the plebiscite each individual doctor is faced with a difficult decision: "To negotiate or not to negotiate on the regulations." To a comparative few the answer will be an incontrovertible "No." Most of these will consist of those retired, senior men near retirement, some who are in salaried jobs, in entirely private practices, or those who have been prominently identified with and advocates of B.M.A. policy. These will say "No" at any price, both to the question of negotiation and that of joining the Service.

Another section of men will say "Yes." Among these will be numbered those who have heavy commitments, unpaid debts, children to educate, and those who are not well up with all that has been written and discussed and has taken place during the past year. Many of these will be doctors working in circumstances or because they prefer it, in isolation. Many men will feel it impossible to say to-day, without further information about terms of service and the inclinations of their fellow doctors, what they are prepared to do in April, 1948. Many will feel it personally safer to say "Yes," with, as Dr. Dain says, the further opportunity of saying whether or not they wish to enter the Service. On the other hand these doctors will be rather intimidated from giving a negative reply because "implicit in such a negative vote . . . is an undertaking, if so advised by the Association, not to enter the Service" (plebiscite form). Their comfort should be the words in [my] italics, as advice to do this will be based on receipt of an adequate majority of negative replies.

Some men in this category may also have been misled by an impression that Mr. Aneurin Bevan, during negotiations on the regulations, may compromise on certain objectionable features of the Act, particularly that of the basic salary. During the discussions in the House of Commons on the negative Lords amendments, the Minister said that he did not want to have

his hands tied on the method of remuneration when he came to discuss matters with the doctors. Also, following a statement by the Lord Chancellor in the Lords when the amendments went back, these crucial items were not persisted in, although Lord Moran and Lord Horder did their best. The Chancellor again gave the impression that remuneration had still to be discussed with the doctors. It should again be emphatically stated that there is no hope whatever that the Minister will, or even can, remove the obnoxious basic salary from the Act. The amount of remuneration is still open to discussion, not the method. Strangely enough this receives no mention in the "Summary of the Act," in the *B.M.J.* In this connexion, some doctors to whom I have spoken in the last few days frankly do not believe that the amount of basic salary can be altered by a stroke of the pen to 100%.

There is, finally, a bulky section of the profession, fully acquainted with the facts and also with heavy responsibilities, who find it difficult to answer "Yes" or "No." Their responsibilities would lead them to answer in the affirmative, while their full knowledge of the implications of the Act and the temperament and mind of Aneurin Bevan make them want to answer in the negative. All such doctors looked hopefully for some more definite leading from the B.M.A., but in vain. They may have good reason for this, in order to get the profession to make a decision without pressure and then stand by it. The answer will more likely be a firm one to a further plebiscite (as I hope) on the question whether or not to enter the Service.

Having analysed the problem as a doctor belonging to the third category, my purpose in writing this letter is to urge the B.M.A. before Nov. 30, by publication of definite inside information about the mind and intentions of him with whom we have to deal, to help us to make what may be the hardest decisions of our lives. This should be done immediately through the columns of the *B.M.J.*, and/or by rapidly called mass or Divisional meetings; and the majority one way or the other will be more decisive if those who answer "No" are also given a later opportunity of saying whether or not they wish to enter the Service if the "Ayes" have it and negotiations do ultimately take place. If the B.M.A. agrees with Dr. Alfred Cox that we, as a profession, are in danger of losing our soul, they should sound the trumpet call with no uncertain sound, "No negotiations." The plebiscite would still give the answer.—I am, etc.,

London, S.W.17

E. GERARD HOUSDEN.

SIR,—A perusal of the plebiscite papers issued by the Association seems to confirm just those fears which I expressed in the letter published in the *Journal* of Aug. 10 (p. 206), namely, that confusion would be created in the minds of a large number of doctors unless the implications of entering into negotiations on regulations are made clear beyond all doubt. In any such discussion the structure of the Act remains unchanged and unchangeable, and the inevitable implication is an acceptance on the part of the negotiators of that structure. To say therefore that discussion does not imply agreement to enter the Service is an empty form of words; for all experience shows that such would be the inevitable result.

So much has been written and said about the Health Service that there is danger that truth may be lost in a fog of rhetoric. It would be tragic indeed if now that it comes to a crucial vote a wrong decision were made through a misunderstanding. It seems a pity that the Association in their final survey have used so much "wrapping" to the "meat." At this late stage therefore I do beg that you will use your columns to bring the issue clearly before your readers and above all briefly and concisely.—I am, etc.,

Derby.

E. D. BROSTER.

Northern Ireland and the Plebiscite

SIR,—We in Northern Ireland are to be asked in the questionnaire whether doctors should negotiate on Mr. Bevan's new Bill. Those of us who signify "No" should realize that we are disagreeing only with the British Bill.

The Northern Ireland Minister of Health, Mr. Grant, a Conservative, who is at present considering an alternative measure, may decide upon: (i) Capitation fee only; (ii) freedom for voluntary hospitals; (iii) right of appeal; (iv) no positive

power of direction; (v) retention of the sale value of practices; and (vi) definite hours of leisure. Then, I think, doctors here could show Mr. Bevan how co-operative they could be with a Bill which satisfies them.—I am, etc.,

Dunzannon.

CONN MCCLUSKEY.

National Health Service

SIR,—I have read with great interest the letters to your *Journal* on the above subject. I should like to comment on one point, namely, the Minister's insistence on the abolition of the buying and selling of practices. The Minister's reason for this is given by Dr. J. R. Salmond (Oct. 12, p. 555): "The Minister states that the sale of practices is abhorrent to him, as it loads the young doctor with debt." This, Sir, is political eyewash! The real reason is that by the abolition of the buying and selling of practices the doctor is handing over his practice to the Government or, more simply, selling his property to the Government, thereby losing his rights and thereby becoming a Civil Servant under complete control of the Government.

Mr. Bevan may offer us 15s. per patient now as a bribe to enter his precious Service, but what is to prevent him from reducing it to 10s. or even 5s. in a year's time or five years' time with some vague political excuse?

One hears people say that the Labour Government is in power and they were given the power by the vote of the people. Are we to be ruled by the vote of a people that cannot think for itself and whose only information is that derived from the Press, which it seems to swallow hook, line, and sinker, and which throws aside Mr. Winston Churchill immediately after victory?

The general practitioners do not seem to be able to expect any help from the specialists. Lord Moran referred to an "unfortunate dispute that had arisen at the eleventh hour" between the Minister and the general practitioners. What does his lordship expect? Does he think we are so gullible and have so little intelligence as to be willing to suffer the dictatorship of Mr. Aneurin Bevan? Does he think that the chartered accountant or lawyer or anybody else that can think for himself is going to be dictated to by some such person as Mr. Bevan? The general practitioners must not be led up the garden path by this clever political eyewash which seems to be blinding the specialists. We must refuse to negotiate with Mr. Bevan so long as he insists on the abolition of the buying and selling of practices, unless and until we desire to become Civil Servants.—I am, etc.,

Marfield.

HUGH TATÉ.

SIR,—In the original Beveridge report, but conveniently omitted from the abridged version and confirmed in the recent debate in the House of Lords by the Lord Chancellor together with an implied and gratuitous insult, control of certification is stated to be essential. In the past we have frequently fought against the encroachments of the State on personal liberty both at home and abroad; the most recent being the last war. This is a Christian country with its inevitable emphasis on the individual and the family. In Fascism, National-Socialism, and Communism the emphasis is on the abnegation of individual freedom and its substitution by a Dictator State. Past correspondence showed that refusal to accept the Service is a strike. It can only be a strike after accepting service. An ancient and honourable profession, going to the very heart of individual and intellectual freedom for a pittance under an alien creed? One may be sure that the first, will not be the last of these encroachments on liberty. May I suggest that the issue is not for debate to be on negotiation, but a simple "Yes" or "No" to the basic principle, Do we accept service under the National Health Act with its inherent infringement of liberty?—I am, etc.,

W. M. RICH.

Training of the Specialist

SIR,—As a recent ex-student of Prof. Harry Platt I read with special interest his excellent letter (Sept. 28, p. 472) on the training of the specialist. The final sentence of this letter read, "The universities also have their part to play by demanding evidence of such a standard of training before they recognize

any individual as a clinical teacher." This brings to notice an important matter of medical reform, especially for the student. I had hoped that in the future better facilities would be given for the teaching of medicine to the man with the calling this somewhat arduous task rather than place the whole medical teaching in the hands of the specialist whose clinical ability remains undoubted but whose teaching ability may be short of the minimum required. I should like to suggest that in the future medical teachers should be chosen not on pure clinical merit alone but for their general characteristics as well. Surely some of our best and most esteemed general practitioners could be asked to give their help in giving to the student medicine at least an inkling of the vastness of medicine practised outside hospitals? After all "the general practice medicine" is the real foundation stone of specialization, this is impracticable I should like to suggest that teachers chosen from those who, apart from their hospital appointments, have spent considerable time in general practice.—I am, etc.,

Taunton and Somerset Hospital.

HUMPHREY THOMAS

Demobilized Specialists

SIR,—At the risk of harping back on a closed subject I should like to put forward a point of view that seems to have been missed from previous correspondence relating to demobilized specialists.

I cannot agree with Lord Moran and others (July 27, p. 1) that the R.A.M.C. officer who attained graded specialist rank during the war should be given special help to continue his specialty. Should this facility be granted it would be at the expense of the medical officer who "risked his neck" in field units. In my experience it was not the best type of officer who filtered into the general hospitals. The doctor who knowingly sacrificed clinical experience to serve at great personal hardship and risk with field medical units will, because of the force of character, make the better specialist if given the chance. It was always possible to volunteer for service with a field unit during the war, if one was physically fit. Therefore medical officers in hospitals were in many cases either physically fit or disinclined for "active service." Neither category I think is specially suited for priority help to attain the higher ranks of our profession. I should like to propose therefore for no official recognition being granted to the fortunate men who attained graded specialist rank during the war.—I am, etc.,

Haifa, Palestine.

J. S. MCKENZIE POLLOCK.

Postgraduate Education

SIR,—In his thoughtful letter (Oct. 5, p. 510) Mr. John Staworthy referred to the kindness and assistance shown him by medical colleagues since he came here, as a stranger, thirty years ago. I would be grateful if you would allow me to voice a similar tribute on behalf of the doctors of another Dominion and to stress how much Australian medicine owes to the gracious reception given to medical visitors from the Antipodes.

My introduction to this facet of medical liaison was in 1911 when postgraduate work had to be found quickly for the medical officers of the Australian Army whose return to their own country was delayed by transport difficulties. On putting the problem before the late Sir J. MacAlister, at the Royal Society of Medicine, his answer was, "If you will find the men we will find the teachers and the facilities." The Fellowship of Medicine was founded early the following year and mainly through its help a large number of our medical men were able to work in the United Kingdom for periods varying from three months up to two years. They carried the gospel back with them to Australia, and their enthusiasm led in 1921–2 to the formation of the Postgraduate Committee in Melbourne, to which Mr. Stallworthy refers. There is now a committee of this nature in each of our capital cities, the one in Sydney being a very live one.

In a recent issue of the *Medical Journal of Australia* the committee announced courses in diseases of women, a twelve weeks' course for general practitioners, courses for Parts I and II of the Master of Surgery, of the diplomas of women's diseases of ophthalmology, of laryngology and otorhinology, and for candidates proceeding to the diploma of psychological medicine.

When there is a need for a dietary supplement 'Wyamin' Capsules will supply the essential vitamins in a readily assimilable form.

Each capsule contains not less than: Vitamin A, 4,500 int. units; Vitamin D, 675 int. units; Vitamin B₁, 100 int. units; Vitamin B₂, Complex containing Lactoflavin, 50 gamma; Vitamin C, 100 int. units; Nicotinamide, 10 mg.

PENICILLIN

in
Meningitis

UNLIKE the sulphonamides, penicillin is normally unable to pass the blood-brain barrier, although there is some evidence that in inflammatory diseases of the brain and meninges this barrier loses some of its effectiveness and permits a certain amount of the penicillin to reach the brain fluids.

Treatment by penicillin is strongly recommended for all pneumococcal, streptococcal (with the exception of some due to *Str. viridans* penicillin-resistant strains), meningococcal and staphylococcal cases, as well as those due to Pfeiffer's bacillus.

The penicillin solution should be injected directly into the cerebrospinal fluid by lumbar, or if necessary cisternal or ventricular puncture.

milar courses are being run in Melbourne. Examinations for a primary F.R.C.S. and M.R.C.O.G. are to be held in Australia early next year, and certain of the courses listed above are designed to be suitable for candidates taking these examinations. This action emphasizes the value which is attached to the demand for, British diplomas. In the years between the wars many Australian medical graduates came to the United Kingdom to work and were warmly welcomed. Everyone was helpful and many of these visitors are now on the staffs of our teaching hospitals.

The end of World War II produced a similar position to that which obtained in 1918. Scores of young medical men who had gone straight from hospital into uniform were being mobilized and were anxious to get back to full clinical work again. Australian universities, general hospitals, and post-graduate committees did all they could, but a considerable number of the applicants wanted to come here, and higher authority encouraged this view. Maj.-Gen. S. R. Burston, D.G.M.S., of the A.I.E., made a special trip home to study the position at first hand and was well received. There were two difficulties: (a) placing men here when they came, and (b) finance to enable them to come. Sir Francis Fraser and his staff undertook the placing, providing numbers were limited at first. The Nuffield Foundation announced their medical fellowships for medical men from the Dominions and India, and the Australian Red Cross made a generous money donation. This fine gesture of the Nuffield Foundation has evidently escaped Mr. Stallworthy's notice. Recent letters do not support a suggestion that "many men are asking why they should cross the world for training, which they may or may not be able to obtain, when they have the assurance of obtaining it much more easily and cheaply nearer home." The number of applicants for the official schemes far outnumber the places available, and many disappointed men are making their own arrangements to come. The official nominees are carefully elected with a view to providing the teachers and research workers of the future, and as such they will mould medical opinion in the years to come. Of necessity there must be a number of men who from one cause and another will have to do their postgraduate training in their own country, but present indications suggest that many of the Australian teachers of the future will have worked, in one capacity or another, north or south of the Tweed. What is valued most is the opportunity to gain an insight into British methods of teaching and the "ideals," for want of a better word, which inspire medical practice in the United Kingdom. Personal contact is necessary for this. The man who describes a trip to this country as "going home" will make every endeavour to do so, whether it be for postgraduate work or for some other laudable reason.

In conclusion, may I support warmly the suggestion in the last paragraph of Mr. Stallworthy's letter regarding the co-ordination of postgraduate units here and overseas and all that this entails. British visiting doctors can be sure of a warm welcome in Australia whether they go out on official or private errands, to lecture to postgraduate classes, or to conduct examinations. In addition to the benefit derived from the interchange of views, such visits enable the hosts overseas to make some little return for the kindnesses which have been extended to them or their friends when in the United Kingdom.—I am, etc.,

JOHN H. ANDERSON.

Ruthin, N. Wales.

Smallpox in the Vaccinated

SIR,—I am glad that Dr. J. Ross Innes (Nov. 2, p. 668) thinks my comments are "most helpful and sound." As I have received far more kicks than halfpence for the views about smallpox and vaccination which I have tried to put over during my professional life it is naturally pleasant and gratifying to receive occasional commendation. For the same reason it is nice to know that Dr. H. Angell Lane, a public vaccinator, approves of my recommendation of "little and often" as the best policy for protecting anti-smallpox staff.

When he states, however, that in the early years of the century I was "claimed by the Anti-vaccination Society as their chief supporter in the medical world" he is, I think, drawing upon his imagination rather than upon facts. It is true that I have often been quoted by *The Vaccination Inquirer*, the

official journal of the National Anti-vaccination League, but that is easily explained, for I have never hesitated to draw attention to facts which told against vaccination as well as to those which told in its favour. I have never attended a meeting of the League, but I once offered to deliver a lecture before them if they would allow me to do so, which offer I may say was politely declined. Moreover, in everything I wrote or spoke about smallpox and vaccination I always tried to make my faith in the efficacy of vaccination to (temporarily) protect the individual quite clear, and it was in the early years of the century (in 1903) that I gave a practical proof of the strength of this faith by taking my wife and two young children into the Leicester smallpox hospital and photographing them by the bedside of a severe confluent case of major smallpox. I told the anti-vaccinists that in denying the power of vaccination to protect the individual they were beating their heads against a stone wall. At the same time, however, I quite admit that I have given the anti-vaccinists credit for several important contentions, which lapse of time has I believe shown to be correct, and which at that period were hotly disputed by ardent pro-vaccinists, e.g., that it was not infant vaccination which was banishing smallpox from this country; that infant vaccination was not necessary for the effective control of smallpox; that vaccination ought to be regarded as a serious operation which was not infrequently attended by serious after-effects, and that therefore compulsory infant vaccination ought to be abolished. To-day, I think, all these contentions will be generally conceded, or at least not seriously disputed, but we ought in fairness to recognize that it has been largely due to the steady and untiring propaganda of the National Anti-vaccination League—apart from the inexorable logic of events—that this great change in public opinion has been brought about.—I am, etc.,

Leicester.

C. KILLICK MILLARD.

Classification of Psychological Disorders

SIR,—With reference to my paper in the *Journal* of Aug. 31 (p. 289), Sir Charles Symonds (Sept. 21, p. 436) has raised some queries in relation to the chronic problem of classification. By not differentiating between anxiety neurosis and anxiety state I have conformed with modern views—see official *Nomenclature of Diseases*, 1931, *Army Classification of Psychiatric States*, 1942, and *Textbook of Psychiatry*, by Henderson and Gillespie, page 423 *et seq.* The latter authorities refer to the special Freudian interpretation of anxiety neurosis, but many other parts of the text do not differentiate between "neurosis" and "state." The same lack of differentiation is apparent in the numerous papers on psychotic breakdown in war, where the terms anxiety neurosis and anxiety state have been freely used, although the term anxiety "neurosis" does not appear in the official military nomenclature. It is obviously significant of the very nature of the problem that most textbooks describe but do not exactly define these conditions.

To economize space on a controversial subject, I would suggest that many further points are best answered by restating some generally accepted principles: (1) The same trauma may produce very different psychiatric reactions in different people; (2) many psychotic patients show neurotic symptoms during the course of their illness; (3) psychiatric illness is rarely entirely due to reactive or endogenous factors; (4) neurotic patients may develop psychosis. As a rule, therefore, there is no "either/or" in the matter; one has to diagnose the predominating pattern of illness, deciding whether this pattern is chiefly depressed in the psychotic or mainly anxious in a neurotic sense. Similarly, psychotic depression or anxiety neurosis (or state) may be mainly reactive or mainly endogenous, hence the considerable inquiry entailed in psychiatric case-taking.

To return to the chief subject of the paper—electric convulsive therapy rather than classification—it should be emphasized that observation of the reaction of the patients showed that it was most necessary to decide whether depression of a psychotic type prevailed as opposed to anxiety, obsessions, or other neurotic symptoms. A certain amount of depression often occurred as a secondary feature in the primarily neurotic clinical picture (i.e., neurotic depression), but the important point for the therapeutic result was correct diagnosis of the prevailing reaction type. Tables (2), (3), and (4) showed that

with the usual E.C.T. frequency of treatment there was considerable difference in the result between these main types, not to mention other responses. The presence of "anxiety neurosis" or of "anxiety state" was of academic rather than practical interest.

It follows that occasionally one will meet a patient in whom psychotic and neurotic factors appear evenly balanced. Such cases are often recent, and more common in the general hospital psychiatric population than in mental hospitals. The decision on therapy may be difficult; hence my remarks on the therapeutic test. Generally speaking, the patients' response to E.C.T. was consistent with the accepted textbook symptomatic classifications, even if it did at times show up one's own diagnostic mistakes.—I am, etc.,

Sutton.

D. E. SANDS.

Priority Foods

SIR,—It amazes me that the Food Rationing Advisory Committee did not think of the milk rationing modifications suggested in this *Journal* by Mr. A. Staveley Gough (Oct. 12, p. 551) and Dr. Lindsey Batten (Oct. 26, p. 626) and in the *Daily Telegraph* of Nov. 8 by Dr. Ellis Parkinson. The cancellation of the meat and cheese rations for all persons suffering from any of the classified diseases except active tuberculosis would certainly effect a considerable economy without harming anyone by greatly reducing the number of claimants.

A reduction in the allowance of priority milk from one pint to half a pint daily could and should often be made. This could surely be safely left to the discretion of the patient's medical attendant. Is there no hope that these suggestions may even now be made to the Minister of Health for his consideration and action?—I am, etc.,

London, S E 12

E. M. LYNTON-LOW.

The Milk Ration

SIR,—The basic ration of milk has come down to two pints (1.14 litre) a week. The minimum priority allowance (except for sick children not attending school) is seven pints (4 litres) a week. It is not reasonable to expect a worker, on the first day of his return to work, to be able to adapt himself to the sudden reduction from seven pints to two pints per week—or to make this sudden adaptation on any other day. Many people, working or aged, get along quite well on an allowance of three and a half pints (2 litres) a week, but not on two pints, especially when this reduced quantity is imposed suddenly after a priority of seven pints.

I suggest that a priority category giving a claim to three and a half pints a week would be welcomed by doctors; that no patients in need of milk would suffer; and that much priority milk could be saved for general distribution. Other sensible suggestions for reductions in priority amounts have been made. By means of this new category a great saving could be made, yet no individual need necessarily have his quantity of milk reduced unless his doctor approves.—I am, etc.,

Crowthorne

H. D. FORBES FRASER.

Legal and Medical Insanity

SIR,—I have read with much interest the various letters in the *Journal* on this important matter. There is, to the informed, a great difference between the two forms of insanity, and if the McNaghten (the name is spelt variously) Rules are given careful study it is impossible to see where they fail to fulfil their object.

The rules are summarized briefly as follows. (1) Every man is presumed to be sane and to possess a sufficient degree of reason to be responsible for his crimes, until the contrary be proved to the satisfaction of a jury. This is one of the presumptions of law just as a man is presumed innocent till found guilty. Furthermore the law of England makes juries the judges of fact, and under our judicial system it is the function of a jury to decide after hearing evidence on the matter to say whether an insane person falls within these rules. (2) To establish a defence on the ground of insanity, it must be clearly shown that, at the time of committing the act, the party at the time was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing, or (if he did know that) not to know that what he was doing was morally wrong. (3) If the accused was conscious that the act was one which he ought

not to do and if that act was at the same time contrary to the law of the land, he is punishable. The test is the power of distinguishing between right and wrong in regard to the particular act committed. (4) Where a criminal act is committed by a man under some insane delusion as to the surrounding facts, which conceal from him the true nature of the act he is doing, he will be under the same degree of responsibility as if the facts were as he imagined them to be.

The words "nature and quality of the act" in No. 2 do not mean the physical act and the morality of the act respectively, but apply alone to the physical character, and were not intended to distinguish between the physical and the moral aspects of the act (*R. v. Codere* 12 Cr. App. R. 21). These rules have been the subject of much consideration and criticism by both medical and legal writers (Stephen, *Hist. Cr. Law*, pp. 124-186; Mayne, *Ind. Crim. Law*, 4th edition, pp. 169 *et seq.*; Wood-Renton in *Lunacy*, pp. 885-914), and Dr. J. A. McCluskie (Oct. 12, p. 555) once again revives the old discussion. I am very surprised to see that Dr. McCluskie asks what is meant nowadays by the words right and wrong; even with the modern trend of living the dictionary meaning of these words has not altered. Surely he does not think it right to kill? Murder, after treason has from time immemorial been regarded as the most heinous crime; and even the learned judge has not a discretion in the punishment once the jury have returned a verdict of "Guilty." He is bound in the absence of a defence of insanity having been established to impose the death sentence.

It would take many pages of your paper to go into this subject at length, but those of your readers interested might read *R. v. Hay* 1899 16 Cape of Good Hope Reports (Sup Ct.) 290; and *R. v. Jessamine* 19 Canadian Crown Cases 214 where in the former case it will be seen that South African (Cape) Law was laid down stating that the capacity to distinguish between right and wrong is not the sole test. Lord Bramwell's apt test is surely the correct one: "They would not have yielded to their insanity if a policeman had been at their elbow," and analysis of the McNaghten Rules surely fits into this saying. Moral insanity as a defence is not yet accepted in England as falling within the McNaghten Rules while insane impulse (kleptomania) is often put forward as a defence in courts of Petty Sessions to charges of petty theft as these courts do not possess the power of ordering an accused person "to be kept in custody as a criminal lunatic." No is a defence of unconscious automatism familiar in our courts unlike Continental tribunals. If careful study is given to the McNaghten Rules a psychiatrist must surely realize where the line is drawn between legal and medical insanity.—I am, etc.

Amoebiasis in Italy

SIR,—Dr. Graham Hayward's interesting article on amoebiasis in Italy (Sept. 28, p. 457), which I have just studied in detail raises several points of interest. The low incidence of bacillary dysentery (104 cases out of 4,601 admissions from June, 1944 to June, 1945) indicates highly successful preventive medicine such as could hardly be expected during the course of an operational campaign. With regard to amoebiasis he points out that in the Burma theatre and in India depressing results followed the standard courses of treatment in contrast to the disease in Italy. The reasons for such results in India and Burma were obvious to any officer who was engaged in the practice of medicine out there. While standard courses of treatment (consisting of emetine injections, E.B.I., "quinoxyl" (chiniofon), and carbarsone) were circulated to all medical units, E.B.I. was unobtainable in Assam and Burma during the whole of 1944 and 1945 while I was serving there. Nor was "quinoxyl" available in sufficient quantities. It is true that E.B.I. was used in certain base hospitals in India, but for case of amoebiasis arising in the campaign none was obtainable at the front. Moreover, while I was serving in a large military hospital in India in 1943 for six months E.B.I. was not available. This state of affairs prevailed in spite of repeated reports of physicians who were responsible for the treatment of cases. I myself mentioned the deficiency in all my official reports and in personal conversation with high administrative officers. Nor could I discover any real reason why, at a time when emetine was being manufactured on a large scale from *ipecaeuana*, E.B.I. could not be manufactured in addition.

ention these points because it is well known that relapsing cases of amoebiasis invalided to this country from India and Burma have frequently proved to be especially resistant to treatment.

As Dr. Hayward points out, the relapse rate has been high when repeated inadequate courses of treatment have been given. I regret that such was the state of affairs for the Burma theatre and to a great extent also in India where the usual courses consisted of injections, carbarsone, and "quinoxyl" retention nemata. It is of the utmost importance that no discredit should be associated with the work of medical officers in the Far East, even under the most severe handicaps on account of the efficiency of E.B.I., which was quite outside our control. Most of us were familiar with authoritative opinion on the treatment of amoebiasis before we ever embarked for the Far East.—I am, etc.,

Windsor.

PHILIP H. WILLCOX.

Posterior Dislocation of the Shoulder

SIR,—Dr. A. McEwen Smith's account of a case of posterior dislocation of the shoulder joint (Nov. 9, p. 694) prompts me to emphasize a point in dealing with these cases which may be important. My experience is confined to three cases, but it is interesting that, of these, two should have been sent to me because reduction was unstable and one to a colleague for recurrent posterior dislocation.

The first patient had several reductions performed by various methods, and each time the joint was felt to click into position, but, as soon as the arm was brought across the chest, re-dislocation occurred. The posterior displacement was not appreciated at this time. When the patient came under my care six weeks had elapsed since injury, and the head of the humerus was plainly felt lying posterior to the glenoid. Reduction was accomplished, not without difficulty, and the arm was immobilized in plaster in ninety degrees abduction and external rotation with the elbow well back: this was the only position in which the joint was stable.

The second case, seen within a few days of injury, presented similar features, in that reduction was easily accomplished by traction in abduction, but re-displacement occurred as soon as the arm was brought into the position for a sling. A shoulder spica, with the arm in abduction and external rotation, was applied and worn for six weeks. Neither case had any associated fracture and both patients were young men. In both the functional result was good a few months later, and as far as is known neither developed a recurrent dislocation.

The early history of the third case was somewhat obscure, but it is certain that treatment was not by a plaster spica in the abducted position. The point to be remembered in treatment is that the position of the usual arm sling is the position of dislocation. Although reduction was apparently stable in Dr. Smith's case, the torn posterior joint capsule has been placed on the stretch during healing. Fortunately the sling was worn only for two days in this instance. In view of the apparently high incidence of recurrent dislocation following posterior displacement of the head of the humerus, it would be interesting to know the final result of Dr. Smith's case.—I am, etc.,

Lactal Duct Obstruction

SIR,—A possible cause of obstruction to the outflow of breast-milk, such as might lead to a breast abscess, is suggested by the following case.

A primipara, two months after childbirth, with lactation fully established, suddenly developed a painful swelling in the area of one sector of the breast. The nipples were of the depressed and furrowed type, and in the position on the nipple corresponding to the affected sector of breast was what appeared to be a blister the size of a pin-head. There was no obvious inflammation, nor before the swelling arose had there been any pain on suckling. Massage of the breast, compression of the lactal sinuses, and the use of the breast-pump were all unsuccessful in overcoming the obstruction. When the "blister" was pricked six ounces of milk were easily expressed and the swelling disappeared.

The condition recurred twice in an adjacent sector of the same breast, a week and a fortnight later. On these occasions there was no obvious "blister," but careful examination with a high-powered hand lens showed a minute fluctuant area slightly paler than the rest

of the nipple, and the same treatment was again successful. The obstructing membrane in each case seemed to be epithelium that had bridged over the furrow at the bottom of which the duct opened.

Had no active treatment been given it seems at least possible that breast abscesses might have resulted. Since on the last two occasions the cause of the obstruction was discovered only by careful search with a lens, one wonders whether this condition may possibly be the cause of breast abscesses more commonly than is realized.—I am, etc.,

VERNON R. PICKLES.

Digital Traction

SIR,—Like Mr. E. G. Slesinger (Nov. 9, p. 709) I have used the method of nail traction in the treatment of fractured phalanges many years ago. When I was house-surgeon under Schnitzler in the years 1929–34 that method was one of the stock methods at that department (Wiedner Krankenhaus, Vienna). I am, however, unable to state what publication caused Schnitzler to use and to teach that method or when and where it might have been published first. Quite likely it was in *Guy's Hospital Reports* quoted by Slesinger. We too found it usually possible to perforate painlessly the free edge of the nail for our purpose.

The nail traction proved useful in many cases, but occasionally we observed one undesirable effect: under the continuous traction the nail loosened, and although by that time the fracture was sufficiently consolidated not to suffer any ill effect, the patients eventually lost the nail and had to put up with the discomfort of it after the original trouble caused by the fracture was got over.

I think that the very occasional occurrence of losing a nail should not necessarily lead to the method being discarded altogether, but I do think that it is well worth keeping the possibility mentioned in mind and perhaps forewarning the patient. In any case I thought it should be mentioned in this correspondence.—I am, etc.,

Gillingham.

K. F. POLLACZEK.

Penicillin-Sulphathiazole Snuff for Nasal Sinusitis

SIR,—Like Dr. J. Ross Macmahon (Sept. 14, p. 403) I have had chronic nasal sinusitis for many years, and like him I have at long last found an effective remedy. Had I thought of penicillin-sulphathiazole powder earlier I should have been spared a very painful third operation which has left annoying sequelae.

The trouble began in 1929 probably provoked by surface diving in deep water. On one occasion water completely filled my sinuses and poured out as from a tap when I lent my head forward to dry my hair. By 1935 persistent catarrh led to investigation which revealed a chronic infection of the left antrum. Lipiodol instillation followed by x ray showed a grossly thickened lining membrane. An anastomosis was performed, but unfortunately closed over soon afterwards. Symptoms persisted and in 1936 the anastomosis was re-opened and enlarged by another E.N.T. surgeon. Lavage was advised and I did this daily with benefit. Crusts of pus blocked the opening whenever I desisted for a few days. In 1939 I met a third E.N.T. surgeon who assured me that lavage was out of date. He advised me to sniff up 1/2% ephedrine in normal saline. Performed daily this enabled the antrum to empty its contents completely about three-quarters of an hour after treatment, and thereafter it usually gave little or no trouble for the rest of the day. The discharge evacuated, however, remained purulent. Moreover the ephedrine solution itself soon became infected from the dropper—a tendency which is little publicized and the prevention of which requires special methods.

In 1945 I had a disastrous case of sepsis following a clean operation. I vowed that I would either get my nose put right or give up surgery. I repaired to the second E.N.T. surgeon and begged him to do something more for me. A Caldwell-Luc operation was accordingly performed. All went well for two days, then a severe infra-orbital neuritis began and continued to give me agonizing pain for nearly a month. I began to wonder whether it was ever going to cease. I feel myself lucky to be left with nothing more serious than some local hyperaesthesia. After this radical procedure the discharge dried up within 2 or 3 months. However, with the first cold it returned and persisted. It was then that I thought of penicillin-sulphathiazole powder. I had some prepared, 250 (later 2,500) units per gramme, and I sniffed a little up my left nostril every morning, with my head over to the left to encourage it to enter the antrum. I tipped a little on to the back of my hand, avoiding

contamination of the contents of the bottle. The results of this simple procedure were a great improvement on lavage or ephedrine. The discharge soon became clear and then decreased in amount. After a while I stopped treatment, but the infection recurred within a few days, and this experience has been repeated on a number of occasions. My wife knows at once when I have not been taking my "snuff" regularly because the smell of the infection returns quickly. This presumably means that the infection is being controlled rather than eliminated. I therefore intend to try taking the snuff twelve-hourly. I shall also test the effect of four daily injections of half a million units of penicillin which Maemahon found effective.

In commenting on the effectiveness of this powder I must emphasize the lack of symptoms of hypersensitivity to the sulphathiazole after almost daily use for over two years. Perhaps I have been fortunate. I am not aware whether the nasal mucosa is as liable as the skin to develop sensitivity. I must add that I have tried this snuff upon a relative who has chronic sinusitis. It was without effect, probably owing to lack of drainage. However, in cases where permanent drainage has been secured I feel confident in recommending trial of this remedy, especially to my surgical colleagues to whom—and to whose patients—this disease is such a curse.—I am, with your permission, writing as—

A SURGEON WITH SINUSITIS.

Clicking Ears

SIR,—The case of clicking noises in the ears reported by Dr. Elliott Emanuel (Nov. 2, p. 652) prompts me to describe a similar case I saw in a Service general hospital in England in 1941.

The patient, a British soldier 21 years of age, was evacuated from Dunkirk nine months previously. He complained of a noise in his right ear which he said was like an alarm clock ticking. True enough a noise, like enough to an alarm clock, could be heard at a distance of two to three feet (60 to 90 cm.) away from the right ear. The noise could also be heard, a little more distinctly, from the front of the patient if he allowed the mouth to open slightly. Wide opening of the mouth, or the use of the tongue depressor, abolished the noise; the tickings recurred on closing the mouth again. No movement of the drumhead was to be seen. There was no defect of hearing. The Eustachian tubes were patent. Clonic movements of the soft palate were seen through the slightly opened mouth. These clonic movements were synchronous with the ticking noises. The clonic movements were abolished by wide opening of the mouth or by the use of the tongue depressor.

The absence of any movement of the drumhead is against the theory that the sound is due to the effect of contraction of the *tensor tympani* muscle on the drumhead. The sound is probably originated at the mouth of the Eustachian tube caused by the spasmodic opening of its lips.—I am, etc.,

Liverpool

G. A. MOULDEN.

"Cord Round the Neck"

SIR, I wish to confirm Dr. L. R. C. Agnew's observation concerning the significance of the advance and retreat of the caput at the end of the second stage of labour. The time comes when one expects the head to be born with the next pain. The pain comes, but the caput advances no more than it did with the previous pains. Then the pain passes and the caput, instead of remaining at the vulva, passes back into the vagina. It appears to recede from one to two inches (2.5–5 cm.).

Many years ago when attending such a case the nurse said to me, "I bet the cord is around the neck." I took the hint and delivered with forceps. The cord was round the neck. It was with pardonable pride the nurse said, "I was right, doctor. I have often noticed it before." I have often noticed it since. It also occurs with a short cord, but then a cord round the neck is also a "short" cord. In these circumstances it is easy to understand how a baby can be born dead. With a contraction the length of the uterus shortens and the baby's head is able to descend until the cord is fully stretched. It can advance no further. When the pain passes off, the uterus relaxes and pulls upon the cord; the cord in turn pulls the baby back into the vagina. If the cord is short there is little risk to the baby, but if the cord is round the neck then that portion which is round the neck is gradually tightened and may not relax. So the circulation is reduced or finally stopped.

When, in an apparently normal case, the head advances and retreats as described, I consider that the diagnosis of cord round the neck rather than short cord should be made, and the baby should be delivered at once. To wait for foetal heart signs may prove to be too late. If the cord cannot be released at once by the usual methods it should be cut between forceps—not between ligatures, as time is precious to the baby.—I am, etc.,

Clones.

M. G. KIRKANS.

SIR,—While we were very interested to read the letter from Dr. L. R. C. Agnew (Nov. 2, p. 668) describing his case of "cord round the neck," we do not agree with his treatment. We feel that time does not allow for the difficult procedure of ligaturing and dividing the cord *in situ*. Under the circumstances he describes we prefer to perform a monolateral episiotomy straight away under light ether anaesthesia, reinforcing it with a few drops of chloroform for the more resistant patient. If she has not delivered herself by the time the forceps are sterilized, we proceed to instrumental delivery, severing the cord en route as need be. If the child is not breathing, we give, simultaneously with the artificial respiration, half an ampoule of "coramine" (nikethamide) direct into the heart, and the remainder of the ampoule goes into the muscles of the thigh.

It is surely not necessary to attempt the refinement of diagnosis of "cord round the neck," nor to attempt the difficult procedure of cord ligature and severance *in situ*; in any case if this is done forceps should be applied immediately afterwards. Time, even to seconds, is the governing factor in the production of a live baby, and when the modern midwife sends in these circumstances, we know we have to get on with the delivery without delay. The modern midwife expects results too.—We are, etc.,

Work of the Government Lymph Establishment

SIR,—In your issue of Oct. 26 there occurs an article on the "Work of the Government Lymph Establishment from July, 1898, to June, 1946" by my ex-colleague Dr. Fremlin who retired from the active staff in 1930. From that date until his untimely death in November, 1945, Lieut.-Col. Stevenson, C.I.E., was solely responsible for the Establishment and was ably assisted throughout by Dr. Butler, M.B.E., who carried on until lymph manufacture by the Government was finally abandoned at the end of June, 1946. Stevenson and Butler held office at the most critical period in the history of the establishment, and to them alone belongs the credit for the maintenance of supplies in 1939–46.—I am, etc.,

J. R. HUTCHINSON.

Medical Research under "Field" Conditions

SIR,—There is a growing tendency in medical research nowadays to investigate disease either in the laboratory or on the patient in hospital. It would seem, therefore, that little or no attention is being paid to the influence of environment upon disease.

The veterinary surgeons have, for some years, been aware of the influence of environment upon disease and have made intensive studies of animal disease under "field" conditions. I would suggest, therefore, that we extend our activities beyond the two compartments now used—namely laboratory and clinical pathology—and develop a new branch of "field" investigation of disease in the patients' own homes, in their workshops, in their offices—in fact under conditions approaching as near as possible to the environmental normal.—I am, etc.,

Runcorn, Cheshire.

NIKETHAMIDE B.D.H.

Nikethamide B.P. has become firmly established in all branches of medical practice. In general practice it should be immediately available for emergency use in cases of collapse, shock or poisoning, and it is prescribed as a routine to overcome the respiratory depression, debility and hypotension associated with various acute infections and the period of convalescence therefrom.

Nikethamide B.P. is issued as Anacardone, for injection in ampoules (Injection of Nikethamide B.P.), and in flavoured 25 per cent. solution for oral administration. Further details are available on request.

THE BRITISH DRUG HOUSES LTD. LONDON N.1

Anecd/E/35a

A Simple and Accurate Tuberculin Skin Test

The application of Tuberculin Diagnostic Jelly A&H to the skin is a convenient and reliable means of detecting positive reactors to old tuberculin. In controlled observations, the results have been as reliable as those obtained with the intracutaneous technique of Mantoux.

The test does not involve the discomfort of injection; it is easily and rapidly carried out; the area of positive reaction is sharply circumscribed; there is no untoward local or constitutional reaction, and no risk of infection.

(See reports, *Brit. med. J.* (1944) i. 531—
Med. Off. (1945) lxxiv. 209—*Lancet* (1946) i. 162.)

It is available in tubes of 2 gm. (20 tests) and 5 gm. (50 tests).

AURO-CALCIUM

Gold therapy now takes a foremost place in the treatment of rheumatoid arthritis. Toxicity, formerly of sufficient severity to detract from its general usage, has been materially reduced by a more careful selection and management of cases, a much lower scale of dosage, and the development of less toxic gold salts.

Crookes Auro-Calcium, a finely divided aqueous suspension of calcium aurothiomalate, provides an appreciable contribution to this reduction of toxic effects.

CROOKES AURO-CALCIUM

Available in single ampoules and in boxes of six ampoules.

Strengths:
10 mg., 25 mg., 50 mg., 100 mg.

THE CROOKES LABORATORIES LIMITED
PARK ROYAL LONDON, N.W.10

For the Disabled and the Infirm

THE ability to get about, to maintain daily interests and social contacts, plays an important part in the continued health and happiness of the disabled and the infirm.

For this purpose the NELCO "SOLOCAR" is ideal. Electrically driven; silent, vibrationless and free from fumes; operated with one hand—effortlessly and without strain—it climbs any hill, travels forty miles without re-charging, passes through most doorways, turns in its own length.

Enquiries for the new post-war models can now be received.
A fully detailed and illustrated brochure will shortly be issued.

The Nelco SOLOCAR

NELCO LTD., Station Road, Shalford, Nr. Guildford, Surrey.

Gently Borne

The rhythmic movement of the gentle wave carries the fallen leaf harmlessly to the shore. Similarly, the gentle rhythmic movement of the peristaltic wave induced by Agarol assures certain evacuation.

The exceptionally stable emulsion of pure medicinal mineral oil softens and lubricates the intestinal contents and thus prepares the ground for the peristaltic stimulus provided by the highly purified white phenolphthalein present in Agarol.

The three principal requirements for the relief of constipation are adequately furnished by Agarol: softening, lubrication, peristaltic stimulation.

Nontoxicity, smaller dosage, effective bacteriostasis are the therapeutic features of 'Sulfathalidine' phthalylsulphathiazole, the new intestinal sulphonamide developed by the Medical Research Division of Sharp & Dohme.

The compound maintains a high concentration in the gastrointestinal tract. Its bacteriostatic action markedly alters the bacterial flora and results in a profound reduction of *Escherichia coli*, *clostridia* and related organisms.

The compound is indicated in the treatment of ulcerative colitis, regional ileitis, as a supplement to therapy of amebiasis, giardiasis, and paratyphoid infections, and as an adjunct to intestinal surgery. Supplied in 0.5 Gm. compressed tablets in bottles of 50, 100, 500 and 1,000.

SHARP & DOHME LTD. HODDESDON, HERTS

Obituary

ARNOLD LYNDON, O.B.E., M.D.

Vice-President, British Medical Association

The death of Dr. Arnold Lyndon, which took place on Nov. 14, in his 86th year, removes from the British Medical Association a prominent member who inspired much affection among his colleagues and who would, but for ill health, have taken even a higher place in its central affairs. He was at one time Deputy Chairman of the Representative Body, but had to withdraw from offering himself for re-election.

Arnold Lyndon qualified in 1885. His student career was highly successful. He took first-class honours in *materia medica* at the Intermediate Examination in Medicine of the University of London in 1884. In 1888 he took the M.D. After serving as house-surgeon and ophthalmic house-surgeon at St. Bartholomew's, where he had won the Brackenbury Surgical Scholarship, and as house-surgeon at the Royal Orthopaedic Hospital, he settled in practice at Hindhead on the border of Surrey and Hampshire, where he built up a high reputation as a general practitioner. He was also consulting medical officer to the Haslemere and District Hospital and an insurance practitioner on the Surrey and Hampshire panels. He threw himself into many local activities, being specially interested in the educational museum at Haslemere, formerly maintained by Sir Jonathan Hutchinson and now a Hutchinson memorial. During the war of 1914-18 he was medical officer and organizer of the Grayshott Auxiliary Hospital, Hindhead, and for his work there he received the O.B.E. In a wider field one of his great interests was Epsom College, of the Council of which he was a member for many years, and he was an earnest propagandist on behalf of that charity. While resident at St. Bartholomew's he had been an enthusiastic member and at one time President of the Abernethian Society. He was an active member of the Medical Defence Union, for many years a councillor, and also a member of the Standing Joint Committee of the Union and the London and Counties Medical Protection Society.

Arnold Lyndon's work for the British Medical Association began in the Surrey Branch, of which he was president in 1922, and honorary secretary for eight years. He had also been joint honorary secretary of the Guildford Division. He was in the best sense of the word a "local man," always keenly interested in the peripheral organization of the Association, with an eye for its weaknesses and its potential strength. Nothing pleased him more, while a member of the Organization Committee, than to analyse the figures of membership of the Divisions and Branches and to strengthen the local organization wherever it showed signs of weakness. He became a representative in 1920 and so remained, with one intermission, until 1931. It was in 1927 that he was elected Deputy Chairman of the Representative Body, and he served in that capacity until 1929.

A position in which he displayed exceptional zeal and ability was as chairman of the Ethical Committee, where his skill in the adjustment of the personal difficulties which often come before that committee was well exemplified. In 1931, on his retirement from the chairmanship of his Local Panel Committee, which he had held for 19 years, and from the honorary secretaryship of the Surrey Branch, Dr. Lyndon was presented with a handsome silver rose bowl and a cheque subscribed for by his colleagues. The testimonial expressed the sense of his unflinching courtesy and suavity, and these were his outstanding characteristics. His membership of the Council extended from 1922 to 1935, and during that time his principal work was done on the Ethical and Organization Committees. On the latter he was chairman of the Grants Subcommittee, a work after his own heart, and he seemed to have at his fingers' ends the necessary particulars with regard to all the Branches and Divisions in the kingdom. Other committees on which he served for shorter periods were the Journal Committee, the Finance Committee, the Public Health Committee, and the Committee on the Peripheral Organization of the Association. The Charities Committee enlisted his special interest, and here his long experience of Epsom College was of great value.

N. E. W. writes :

The present generation of practitioners in Surrey can have little knowledge of the amount of work Lyndon put in on their behalf. He held every position in the Division, on the Branch Council, and on the Local Medical and Panel Committee in which he could render service to his colleagues. His wisdom and experience were recognized by all, and he seldom had any difficulty in bringing a meeting round to his point of view. No slipshod or ambiguous resolutions ever got past Lyndon. He always insisted on the decision of a meeting being expressed in precise and unequivocal terms. Ill health prevented him from continuing all his activities, but he remained treasurer of the County Local Medical Committee to the end, and attended a meeting as recently as two months ago. His particular interest was the benevolent side of the work of the committee, and he was their trusted adviser as to how the considerable sum raised for charitable purposes should be distributed. Others will have written of Lyndon's many other activities, but it is fitting that Surrey should pay a tribute to Arnold Lyndon and express its gratitude for the services he rendered.

HARRY ROBERTS, L.M.S.S.A.

The death of Dr. Harry Roberts on Nov. 12 has taken away a man of uncommon talents, with a personality all his own. He was a good doctor to countless poor people, a clear thinker who wrote very well on many topics, a stimulating companion, and a loyal friend. He was a practising sociologist long before "medical sociology" was spoken of or "social medicine" received a name. His gift for arranging the week's work enabled him to put every hour to the best use and to combine the life of a busy East End practitioner with authorship of high quality, the pursuit of many intellectual tastes, and the cultivation of his garden and orchard.

Harry Roberts came of West Country yeoman stock. He was born at Bishop's Lydeard, Somerset, on Sept. 30, 1871, and was educated at Queen's College, Taunton, at University College, Bristol, and at St. Mary's Hospital, London, and qualified in 1895. After a few months spent in teaching elementary science he began work as a general practitioner in Cornwall; but, though he loved the countryside and liked driving about behind a horse, the mental stagnation of the neighbourhood was more than he could bear. So he came to London, not, however, to practise in the centre or the West End, where he could rub shoulders with educated people every day, but to put up his plate in Stepney, at a good house amid the enveloping slums. In 1909, when this East End practice was being built up on novel lines, Neil Lyons wrote a book about it called *Sixpenny Pieces*, which in a rather jaunty and florid way took Harry Roberts as the central figure ("Dr. Brink") for a series of vignettes of life in a very poor and rough quarter of London before the coming of the National Insurance Act. The work went on after 1912 and the practice grew, the senior partner spending many week-ends away from 63 Harford Street at his country house at Hawkey, near Liss in Hampshire, where he read and wrote and gardened and talked with congenial friends. Some seventeen years ago, when Roberts was still actively running his well-organized treatment centre, the firm came into collision with the London Insurance Committee on a charge of "excessive prescribing"; they were fined £100 notwithstanding tributes from the referees to the admirable ideals of the four doctors and the "high efficiency of the treatment given by them in a poverty-stricken neighbourhood." The case dragged on and Roberts fought it with persistence and skill in argument. The Minister upheld the penalty, but those who knew what Harry Roberts was doing for the poor of Stepney felt that justice had not been done—far from it.

He was a frequent contributor to the leading reviews and occasionally wrote for medical journals. Many of his social, political, and philosophical articles reappeared in book form. He also published books on the history and practice of gardening and on everyday hygiene and psychology.

Dr. GEORGE ALEXANDER WILLIAMSON, who has died in retirement, twice held office at Annual Meetings of the B.M.A.—as secretary of the Section of Tropical Medicine at Aberdeen in 1914, and as vice-president of the Section of Services and Tropical Medicine at Aberdeen in 1939. He was born at

Inverness in 1871, son of Alexander Williamson, J.P., and was educated at the Royal Academy and College, Inverness, and at Aberdeen University, graduating M.A. in 1889, M.B., C.M. in 1893, and M.D. in 1899. He took the Liverpool D.T.M. in 1906 and the D.P.H. of Aberdeen (with honours) in 1910, and received the Certificate (with distinction) of the Liverpool School of Tropical Medicine. After holding house posts at Elgin and Inverness he became District M.O. for Cyprus in 1895, and retired from the Colonial Medical Service in 1911. Returning to Scotland he became lecturer in tropical medicine at Aberdeen University, and during the war of 1914-18 served with the Egyptian Expeditionary Force with the rank of major, R.A.M.C.(T.A.), and was mentioned in dispatches. Dr. Williamson published several papers on tropical diseases and had been medical officer and lecturer on hygiene at the Aberdeen Training Centre under the National Committee for Training of Teachers.

We regret to announce the death of Dr. ANDREW BROWN MURRAY, of Banff, who had been chairman of the Banff, Moray, and Nairn Division of the B.M.A. and represented it at ten Annual Meetings; he was also president of the Northern Counties of Scotland Branch in 1938-9. Dr. Murray studied medicine at the University of Glasgow, graduating M.B., C.M. in 1897, and was then in turn house-surgeon and house-physician at Greenock Royal Infirmary and Fever Hospital, and assistant medical officer to the Metropolitan Asylums Board. Settling in practice in the north of Scotland, he became medical officer of the parish of Banff and Boyndie, and visiting physician to Chalmers' Hospital, Banff. He had been Provost of the Royal Borough of Banff, and J.P. for the county since 1919. He was at one time a keen Territorial officer, reaching the rank of major, R.A.M.C.(T.A.), and receiving the Territorial Decoration. He was also vice-president of the Banffshire Field Club and a member of the County Education Authority for some years.

Dr. HUGH DAVENPORT LEDWARD, who died on Oct. 19 after several years of incapacity through illness, aged 68, was the son of the late H. D. Ledward of Bowdon, Cheshire, in which town he went to school. Thence he entered Trinity College, Cambridge, where he was placed in the First Class of the Natural Science Tripos in 1899. The following year he gained the University Scholarship at St. Bartholomew's Hospital, London, and qualified M.R.C.S., L.R.C.P., in 1902, becoming M.B., B.Ch.Camb. a year later. He was house-surgeon to Sir D'Arcy Power at that same hospital, and house-physician at the Brompton Chest Hospital. When Letchworth Garden City was in its infancy he settled there in partnership with Dr. Norman Macfadyen, and remained there from 1905 until his retirement for health reasons in 1936. In 1916-18 he served in the R.A.M.C. with the 60th General Hospital at Salonika and elsewhere. To all his friends he was endeared by a modest, quiet disposition which by no means prevented widespread recognition of his professional abilities at Letchworth, where he is still affectionately remembered. In 1910 he married Miss Lilian Grace Gibb, who survives him: their only daughter died in childhood; their son is Dr. A. D. Ledward, now practising at Sandwich after service during the recent war. Dr. Ledward joined the British Medical Association in 1908; he was secretary of the Section of Medical Sociology at the Annual Meeting of 1913, and chairman of the East Herts Division, 1922-3. He was a member of the Representative Body in 1912 and 1913.

We regret to announce the death of Col. GEORGE A. TROUP, M.D., C.M., D.P.H., on Oct. 24, at his native village of Rhynie, Aberdeenshire, where he and a brother had resided together in recent years. He was educated at Gordons College, Aberdeen, and after graduating in medicine at the University there joined his cousin, the late Dr. P. J. S. Nicoll, in 1894 in private practice at Romford Road, Stratford, London. Later, in addition he was appointed a consulting physician at Queen Mary's Hospital for the East End, which position he held for many years. After the death of his partner in 1926 Dr. Troup lived for a time at Wanstead, but later moved to Loughton in Essex. It was soon after his complete retirement from practice in 1940 that he took up residence in Rhynie where, as a Trustee of the Nicoll Hospital in particular, but in other matters of local interest too, he found pleasure and interest in affording help and guidance. Col. G. A. Troup, T.D., served in the R.A.M.C. in Gallipoli and Palestine with distinction, was mentioned in dispatches, and became an A.D.M.S. He was appointed a Deputy Lieutenant for the County of Essex, and it is believed that his interest and work for the Territorial Association subsequent to the War of 1914-18 led to his receiving that appointment, which, however, he resigned on leaving the county for Scotland. He had a kindly disposition and was held in very high esteem by his patients and fellow medical practitioners,

and it is known too that during his long career in the Army Medical Service he held the confidence of those with whom he served.—A.L.

Surg. Lieut.-Cmdr. W. F. VIRET, D.S.C., who was demobilized in December, 1945, died at Bradford on Oct. 23 after a short illness. He had served in the Royal Navy for 10 years. The second son of the late Dr. B. P. Viret, of Bradford, he was 36 years of age and had been educated at Bradford Grammar School, Leeds University, and University College Hospital, London. He qualified in 1935 and entered the Navy after a period spent as house-physician at Leeds General Infirmary. During the early part of his naval career he served on a river gunboat on the China station and in the recent war he was first attached to a destroyer engaged in the Channel patrol. Later he went to the Mediterranean as Surg. Lieut.-Cmdr. in the cruiser H.M.S. *Aurora* and saw a great deal of active warfare. In 1944 he was awarded the Distinguished Service Cross for conspicuous bravery and devotion to duty. After demobilization in 1945 he went into practice with his brother and sister-in-law (Drs. R. P. and Elizabeth Viret) at Shipley, Yorks. In 1940 he married Penelope Mary Downes and had a son and a daughter. A colleague writes: Wilfrid Viret was a man of sterling character, wide sympathies, and sound judgment. He was vigorous in mind and body and therefore it is all the more tragic that he should have been struck down by a sudden, fulminating infection. The country can ill afford to lose a man so devoted as he was to his profession, his patients, and his family.

Dr. JOHN SOUTTAR MCKENDRICK, who died on Oct. 31, held office as President of the Royal Faculty of Physicians and Surgeons of Glasgow in 1939-40. He was born on March 5, 1874, son of John Gray McKendrick, emeritus professor of physiology in Glasgow University. From Kelvinside Academy he entered the University in 1891 and graduated M.B., C.M.Glasg. with high commendation in 1896, proceeding M.D. with first-class honours and the University gold medal three years later. He was elected F.R.F.P.S. in 1902 after holding resident posts at the Western Infirmary, where subsequently he served as a member of the visiting medical staff for many years. In the early part of his career Dr. McKendrick was assistant to the professor of medicine, Sir Thomas McCall Anderson, and assistant lecturer in practical physiology in Glasgow University under his father. During the war of 1914-18 he was physician to Bellahouston Red Cross Hospital. The Royal Society of Edinburgh elected him a Fellow in 1900, and he was a member of the Association of Physicians of Great Britain and Ireland. He contributed papers, mainly on clinical subjects, to this and other medical journals. He had been a member of the British Medical Association for 42 years.

It will be difficult (writes K. P. H.) for the non-official medical fraternity of Assam to become accustomed to the fact that FREDERICK MCCOMBIE, who died in Shillong at the end of July, is no longer with us. He was, without any question, the doyen of the profession here, having spent the whole of his working life in Assam and having been accorded every honour possible to a non-official. He qualified M.B.Lond. in 1904 after a brilliant career at King's College, which he entered with a Clothworkers' School Exhibition, and immediately came out to India as assistant to Dr. Gregerson of Tinsukia, Assam. Within a very short time he had shown his scientific interest in tropical medicine by publishing a paper in 1906 on the then almost unknown method of treatment of cholera by saline injections. On his chief's death (he was murdered by the Abors when on a hunting expedition) he succeeded to the practice and remained in the area for the rest of his life. In 1912 he became B.S.Lond. and M.R.C.S., L.R.C.P., and took his M.D. in tropical medicine and the D.T.M.&H. of Cambridge. About this time he helped to found the Assam Branch of the B.M.A., in which he took an interest to the very end. He was President of the Branch on many occasions, his last period of office being during the year 1944, and chairman of the Assam Valley Division on even more. His happiest moments were probably those when he was associated with his colleagues at meetings of the Association, where his sane and sound counsel was always sought. He was also for many years a keen member of the Assam Valley Light Horse, being promoted to the rank of Lieut.-Col. and receiving the Volunteer Decoration. The confidence placed in him by his fellows was shown by his membership over a long period of the Assam Medical Council, of which he was an elected member. "Freddie" never married, but many in Assam will mourn his loss. He never spared himself to help his younger colleagues and he salted any criticism with his typical dry humour. He was what he wanted everyone else to be—a good B.M.A. man—and Assam will not know his like again.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a Congregation held on Nov. 2 the following medical degrees were conferred:

M.D.—M. A. Rushton.
M.B., B.Chir.—J. W. Ker (by proxy).

UNIVERSITY OF LONDON

The title of Professor of Morbid Anatomy and Histology in the University of London has been conferred on Dr. Robert Wilfred Scarff in respect of his post at Middlesex Hospital Medical School, as from April 1, 1946.

Pathological appointments held for at least six months in the laboratories of the public health service at Colindale, Cambridge, Oxford, and Cardiff have been approved for the purposes of admission to the M.D. examination, Branch II (Pathology), but the matter will be further considered in the session 1950-1.

The University of London Conservative and Unionist Graduates Association is reorganizing after seven years of suspension and will hold its first post-war general meeting at King's College, Strand, W.C., on Saturday, Nov. 30, at 11 a.m. Mr. R. D. Milne, M.A., 15, Avenue Road, Highgate, N.6, is acting hon. secretary until a new appointment is made.

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council on Nov. 8 the following appointments were made: *Lecturer in Pharmacology*, D. R. Wood, B.M., B.Ch.; *Research Fellow and Tutor in Therapeutics*, J. F. Goodwin, M.D., F.R.C.P.; *Research Assistant in Medicine*, Margaret H. Miller, M.B., Ch.B.; *Demonstrator in Pathology*, J. D. Hopewell, M.B., Ch.B.; *Part-time Demonstrator in Physiology*, Ursula S. Gray, M.B., Ch.B.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

Sir Arthur MacNalty, K.C.B., D.M., will deliver the FitzPatrick Lectures on Tuesday, Dec. 10, and Thursday, Dec. 12, at 5 p.m., at the College. Subject: "The History of State Medicine in England." (1) From the Accession of Queen Victoria to the General Board of Health. (2) The Medical Department of the Privy Council.

At a quarterly comitia of the College, held on Oct. 31, with the President, Lord Moran, in the chair, Sir Archibald Gray, Dr. Macdonald Critchley, Sir Lionel Whitby, Prof. A. A. Moncrieff, and Dr. Janet Aitken were elected Councillors.

It was agreed that an International Congress of Medicine should be held in Sept., 1947.

It was also decided that there should be an organization of the Members of the College with provision for meetings and the election of two representative Members to serve on the Council.

Reports were received and approved from the Paediatric Committee and the Committee on Dermatology.

On the nomination of the Council the following were elected representatives of the College: Dr. C. M. Hinds Howell on the committee of management of the Conjoint Board; Dr. F. S. Langmead on the Central Midwives Board; and on the Standing Joint Committee of the three Royal Colleges, the President, Sir Leonard Parsons, Dr. H. E. A. Boldero, Dr. W. G. Barnard, and Sir Allen Daley. Dr. C. M. Hinds Howell, Dr. M. E. Shaw, Dr. J. B. Harman, and Dr. J. C. Hawksley were elected representatives on the Committee of Reference, and Dr. Hinds Howell and Dr. Harman on the Central Medical War Committee. Dr. John Parkinson was elected the representative of the College on the committee of management of the Canadian Red Cross Memorial Hospital, Taplow.

It was announced that Prof. G. Selby Wilson had been appointed Milroy Lecturer for 1948, his subject being "The History, Design, and Purpose of the National Public Health Laboratory Service."

Mr. Francis M. Stent was appointed secretary of the Examining Board.

The following, having satisfied the Censors' Board, were elected Members of the College:

R. A. Andrew, M.D., B. Antonious Bactor, M.B., Major J. P. Baird, M.B., R. A. M. C., Margaret R. Becklake, M.B., J. F. Bolton Carter, M.B., A. S. V. Burgen, M.B., A. D. Charters, M.D., S. Chaudhuri, M.B., C. J. M. Clark, M.B., P. Corridan, M.B., P. J. N. Cox, B.M., W. S. McR. Craie, M.D., J. P. Crawford, L.R.C.P., F. E. Crawley, M.D., F. W. Dickson, M.B., K. W. Donald, M.D., R. G. Evans, M.B., Mary Farquharson, M.B., R. Fletcher, M.B., S. Grieve, M.B., L. G. Hannah, M.B., J. N. Harris-Jones, M.B., A. R. Harrison, M.B., B. E. Heard, M.B., M. S. R. Hutt, M.B., R. J. Isaac, L.R.C.P., A. H. James, B.M., B. Lees, L.R.C.P., M. I. Levin, M.B., R. B. Lucas, M.D., J. Luder, M.B., Fl. Lieut. D. H. Mackinson, M.M., R. A. F. V. R., R. B. Martin, M.D., Lieut.-Col. A. N. T. Meneces, M.B., R. A. M. C., G. El D. Nor el Din, M.D., B. D. Patel, M.B., P. D. Sarnan, M.B., I. Schirre, M.B., Esther E. Simpson, M.B., Jean V. Simpson, M.B., A. J. Singh, M.D., B. C. Sinha, M.B., Y. G. Sofer, M.B., G. S. C. Sowry, M.B., C. A. Storr, M.B., G. B. Stratton, L.R.C.P., W. St. C. Symmers, M.B., M. Symons, M.B., R. B. Terry, M.B., A. J. Thomas, M.B., J. Vallance-Owen, M.B., C. E. Van Rooyen, M.D. (in absentia), R. P. Varin, M.D., A. G. W. Whitfield, M.B., A. W. Williams, M.D., D. I. Williams, M.B., G. M. Wilson, M.B., L. Wolman, M.B., C. Zahra Neumann, M.D.

Licences to practice were conferred upon the following 114 candidates (including 22 women) who had passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board and have complied with the necessary by-laws of the College:

Ruth Ainsworth, T. W. Backhouse, W. O. Backus, P. T. Ballanyne, P. J. Banks, B. W. Barras, J. H. Beaton, R. W. Bell, P. L. Berger, P. G. Bevan, I. A. Blackmore, R. W. Booth, R. W. A. Bottoms, W. I. H. Bourne, L. W. Bowen, P. A. Boxall, T. Brandl, D. S. N. Brierley, F. B. Briggs, M. H. Brook, Brenda M. Buck, P. J. Burdon, Yvonne B. Capon, Sybil C. Capper-Johnson, P. J. Chapman, Patricia Chippindale, H. E. Christensen, L. W. Clarke, P. W. Clemeats, R. A. Cocks, J. F. Cogan, W. A. D. Combe, A. T. Cook, D. C. Cooke, H. S. Coulsting, Mary Creevey, T. Crisp, D. W. J. Cullingford, H. Dasch, A. J. A. Dawes, R. A. Dawes, K. R. Dempster, R. D. Eastham, W. McC. Edgar, G. B. Elliott, Kathleen A. Elliott, Audrey T. Evans, I. A. Falner, J. Fairlie, Joyce Faulkner, M. E. Fearnley, E. C. Fleming, L. Ford, R. H. Fox, H. H. Frank, Margaret A. Gee, J. H. H. Gibbon, A. W. Guffman, Jean F. Gordon, W. V. Graham, G. J. Hadfield, A. A. Hall, P. S. Hall, J. L. Harris, J. B. Hearn, Erica W. Higsons, A. H. Jennings, Gwyneth M. V. Johns, R. F. D. Horn, B. B. Jakeman, J. L. Jenman, J. R. Leslie, H. M. Lyons, H. J. Johns, H. G. Mather, D. McK. Maxwell, P. R. H. Moleworth, Nestor G. Moron, G. O. Morse, J. E. Owen, P. N. Porritt, Alice M. Pandrill, J. H. S. Perrett, T. L. Pilkington, N. C. D. Pizey, P. N. Porritt, Eva M. Raybould, B. F. Richards, D. A. Richards, Betty Scotter, S. Silbermann, M. Silverberg, J. P. A. M. Skene, Gwendolen D. Smith, Margaret T. Smith, Patricia E. Smith, M. J. Squires, B. H. Storey, M. Strobe, W. Wagland, H. Walters, L. G. R. Wand, G. B. B. White, A. MacR. Whittington, K. L. Williams, P. H. Williams, T. B. Williamson, Audrey J. Worman.

Diplomas in Ophthalmic Medicine and Surgery, in Tropical Medicine and Hygiene, and in Physical Medicine were granted, jointly with the Royal College of Surgeons of England, to the successful candidates whose names were printed in the report of the meeting of the Royal College of Surgeons of England in the *Journal of Oct. 26* (p. 630).

Diplomas in Child Health were granted, jointly with the Royal College of Surgeons of England, to the successful candidates whose names were printed in the report of the meeting of the Royal College of Surgeons of England in the *Journal of Oct. 26* (p. 630) and to H. G. Farquhar, E. Kahn, Margaret Munro, and A. M. Young.

Diplomas in Medical Radiotherapy and in Medical Radio-Diagnosis were granted, jointly with the Royal College of Surgeons of England, to the following successful candidates:

MEDICAL RADIO-THERAPY.—S. Curwen, R. F. Hendlass, C. L. Lewis, T. McK. Robb, W. R. Ward.

MEDICAL RADIO-DIAGNOSIS.—J. Aspin, R. F. Ashwin, A. T. Aylmer, W. M. Forster, S. Haase, H. A. R. Hamilton, W. S. Holden, F. L. Ingram, S. J. Johnson, A. M. Jones, D. R. Mailand, J. H. Middlemiss, K. D. F. Morie, E. H. Mucklow, C. Pickard, R. A. Reynolds, W. H. T. Shepherd, T. Stephanides, G. H. Thomas, M. R. Tomlinson, H. J. Trenchard, P. Watts, W. J. R. Wyness.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A Commonwealth Travelling Professorship

The following announcement was made by the President, Sir Alfred Webb-Johnson, at the Buckston Browne Dinner at the Royal College of Surgeons on Nov. 14:

A prominent New Zealand industrialist has made an anonymous gift to the Royal College of Surgeons of England for the endowment of a Commonwealth Travelling Professorship. The endowment will provide an income of about £2,000 a year, and the benefaction is to be known as a gift from "A New Zealand Family." A Commonwealth Professor will be appointed each year and will generally be a prominent physician, surgeon, or scientific worker resident in Great Britain or in Australia or New Zealand. The appointing authorities are also empowered, however, to elect as a professor a distinguished teacher from one of the other Dominions. The professor will be required to travel from the country where he or she is ordinarily resident to Great Britain, or to Australia and New Zealand, and to any other Dominion of the British Commonwealth, for the purpose of assisting in the advancement of medical science either by lecturing, teaching, or engaging in research. It is hoped that the institution of this professorship will not only lead to the establishment of closer links between scientific workers in the Dominions and in the older seats of learning and centres of research, but that the people of all nations will benefit. It is also hoped that it will be an important contribution to Imperial unity.

General Annual Report

The general annual report for the year ending July 31, 1946, has been printed for the Council and gives a record of the work of the College in its various departments during that period. As was announced in the annual report for 1944, the Council is applying for a grant for a Supplemental Charter to enable the College to expand its activities and effect reforms in its administration. During the year 86 Fellows, 581 Members, and 98 Licentiate in Dental Surgery were admitted after passing the College examinations. Prof. F. Wood Jones assumed office as Sir William H. Collins Professor of Human and Comparative Anatomy at the beginning of 1946. The pathological specimens have been returned to the College, and the reorganization of the collection has been continued under Prof. R. A. Willis, the Sir William H. Collins Professor of Pathology. The return of evacuated books and the

re-equipment of the main book-stack, with its shelving, were completed early this year. The rearranging of the books returned from the country continues, and a start has been made with the repair and rebinding of the historical collections. Considerable success has been achieved in making good the gaps in wartime periodicals from America, France, and neutral countries. The return of the laboratories of the College from evacuation at Finchfield, Essex, was completed in August, 1945, but the disturbance caused in the laboratories by war damage repairs and the urgent needs of the other scientific departments made necessary a further evacuation of the Department of Experimental Research, and the Bernhard Baron Professor and his staff obtained hospitality in the Department of Physiology at Cambridge. Since May, 1946, Prof. John Beattie has been in Germany as head of a group of workers who are investigating further the problem of famine oedema. The policy of the College to provide postgraduate education has been considerably expanded, and a course of 69 lectures on anatomy, applied physiology, and pathology was arranged for September-October, 1946. For the first time in the history of the College the assets stand at over one million pounds. A third grant of £100,000 from Sir William H. Collins was the principal increase of capital which has enabled the College to reach this notable point and to further the work of the scientific departments. The restoration fund stood at £141,000 on Aug. 1, 1946, including recent gifts from America, Australia, and New Zealand.

The Buckston Browne Dinner

At the annual dinner of Fellows and Members held at the College in Lincoln's Inn Fields, the President made the announcement printed above concerning the Commonwealth Travelling Professorship. He also read a message received from the King assuring the College of his interest in its many activities and saying that the new professorship should be of great benefit to medical science throughout the Commonwealth and Empire. In a letter on the same subject the Prime Minister wrote that one of the means by which the British peoples could remain in the foreground of medical science was by exchange of ideas and knowledge. Sir Alfred Webb-Johnson, in a general welcome to the guests, said that this was a domestic occasion endowed by Sir Buckston Browne, one of the best and most lovable of men and a great benefactor of the College. Addressing the Minister of Health he asked: "Can we get together and talk over the extraordinary activities of the Government and see if we can make sense of them?" And he told of a long visit paid by Mr. Aneurin Bevan to the College and the keen interest he showed in its work. The benefactions received by the College were a great inheritance for great ends. The work was already expanding in many directions, and in September of this year the attendances at lectures were no fewer than 9,000.

During the evening the Honorary Medal, instituted in 1802 and awarded only twenty times before, was handed by the President to Sir Alexander Fleming, F.R.C.S., whom Sir Heneage Ogilvie, Senior Vice-President, introduced in a felicitous speech. Replying to a toast to the guests Lord Addison, F.R.C.S., Secretary of State for Dominion Affairs, expressed his admiration for the enterprise now shown by the College and spoke of London's unique opportunity for postgraduate teaching. Mr. Bevan, who followed, said that he need not make a speech at this family affair, but he was impressed by the graceful symbolism of the New Zealand gift, which seemed to him even more important than its content, and he paid a tribute to Sir Alfred Webb-Johnson's great work for surgery and interest in young men. The High Commissioners for New Zealand and for Australia also replied to the toast.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At a quarterly meeting of the College, held on Nov. 5, with the President, Dr. D. M. Lyon, in the chair, Dr. A. MacA. Gillespie (Edinburgh), Dr. A. M. MacDonald (Edinburgh), Dr. R. A. Miller (Edinburgh), Dr. G. O. Horne (Edinburgh), Dr. R. J. Kellar (Edinburgh), Dr. G. D. Maleolm (Bridge of Earn, Perthshire), and Sir Andrew Davidson (Edinburgh) were introduced and took their seats as Fellows. Dr. H. J. Parisi (Pettis Wood, Kent), Dr. P. V. Pritchard (London), Dr. R. C. Wood (Edinburgh), Dr. P. N. Bardhan (Ferozepore, Punjab), Dr. H. M. D. Shepherd (Shanklin, I.O.W.), Dr. J. A. Malloch (Edinburgh), Capt. J. W. D. Goodall, I.M.S., Major J. Mackay-Dick, R.A.M.C., and Dr. D. M. Anderson (Braintree, Essex), were elected Fellows of the College.

Drs. A. Rabinowitz (Johannesburg), A. Brinks (Germiston, S.A.), W. Henderson (Edinburgh), J. H. D. Millar (Edinburgh), R. H. M. Ross (Darlington), L. S. Prasad (Bihar, India), N. S. Gordon (Edinburgh), G. H. Armitage (Cummock, Ayrshire), M. M. Whittet (Glasgow), Elizabeth M. Hislop (Edinburgh), and I. Wang (Edinburgh), were elected Members of the College.

The Cullen Prize, 1946, was awarded to Lieut.-Col. W. F. Harvey, C.I.E., F.R.C.P.Ed., I.M.S. (ret.). The Hill Pattison-Struthers bursaries in anatomy and physiology were awarded to M. C. Berenbaum and J. Jackson. The Hill Pattison-Struthers bursary in clinical medicine was awarded to Dr. J. L. Quartey-Vandercuije.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

The following candidates have been approved at the examination indicated:

DIPLOMA IN OBSTETRICS.—T. M. Abbas, J. S. Atbury, R. H. O. Bannerman, A. Barker, A. P. Bates, T. C. Beard, A. V. G. Bibby, J. M. Bowen, S. Burke, D. J. Burnett, Diana Butler, P. H. Cardew, T. E. A. Carr, Betty J. Clymo, C. K. Cole, N. K. Crooke, T. K. Davies, Ruth M. Dearing, Janet M. Done, Kathleen A. Drury, R. C. Dwyer, C. T. F. Ealand, W. S. R. Fenton, H. Flack, Mary Francis, W. K. Frewen, Kamel Girgis, Mary E. Goodson, A. H. Grenz, G. E. R. Hamilton, Emily G. Hamlyn, J. R. Hassan, Lore M. Hasslaeher-Traub, J. J. Hayward, Mary A. Hewett, Monica M. Hogben, F. L. E. SOCIETY OF APOTHECARIES OF LONDON

On Thursday, Nov. 28, at 8 p.m., the Master, Wardens, and Court of the Society of Apothecaries of London will present the Society's gold medals in therapeutics to Sir Alexander Fleming and Sir Howard Florey in recognition of their work on penicillin. The presentation will be followed by a soiree for the members of the Society.

Medical News

Abstracts of World Medicine and Abstracts of World Surgery. Obstetrics and Gynaecology will make their first appearance in January, 1947. These two new journals are being published monthly by the British Medical Association, the first at an annual subscription of 3 guineas and the second at 2 guineas. Applications for subscription should be sent to: The Publishing Manager, *British Medical Journal*, B.M.A. House, Tavistock Square, London, W.C.1.

The Family Planning Association (69, Eccleston Square, London, S.W.1) has arranged a Medical Conference to be held at Gas Industry House, Hyde Park Corner, S.W., on Sunday, Nov. 24, at 10.30 a.m., when medical officers from a county council and from a borough council will open a discussion on "The Experience of some Local Authorities in providing contraceptive advice within the terms of the Ministry of Health Memoranda"; this will be followed by a discussion on "Clinical Problems in Contraceptive Technique and the Atypical Case." At 2.30 p.m. "Developments in the treatment of Sub-Fertility and their application to Clinics" will be discussed. A film, made in the United States, entitled "Studies in Human Fertility" will be shown at the end of the conference.

The Medical Society for the Study of Venereal Diseases will hold a general meeting at 11, Chandos Street, Cavendish Square, London, W.1, on Nov. 30, at 2.30 p.m. Dr. J. A. W. McCluskie will give an address on "Cardiovascular Syphilis."

The Edinburgh University Club of London has arranged to hold a reception at the May Fair Hotel, London, on Thursday, Dec. 5, 6.30 to 8 p.m., in honour of the Principal, Sir John Fraser, Bt., and Lady Fraser. Any member who has not received a notice by Nov. 25 is requested to get in touch with the Hon. Secretary at 12, Wimpole Street, London, W.1.

A meeting of the Scottish Group of the Association of Industrial Medical Officers will be held at the Institute of Hygiene, University of Glasgow, on Wednesday, Dec. 11, at 3 p.m., when there will be a symposium on "Occupational Medicine" by Prof. T. Ferguson and assistants. All medical practitioners interested are invited to attend.

At a meeting of the court of directors of the Society for Relief of Widows and Orphans of Medical Men, held on Oct. 9, with Dr. R. A. Young, President, in the chair, the death of a member was reported and two new members were elected. The death was also announced of a widow who had received £1,261 in relief since 1932. The half-yearly accounts to June 30 which were presented showed that £1,940 had been given to widows. It was reported that the widow of a member had applied for relief and a yearly grant of £60 was voted. It was decided to make a Christmas present to the widows. A donation of £31 5s. was received from the Bovril Medical Agency. Members who have been demobilized should send their new addresses to the secretary, as until they have paid the arrears of subscriptions their membership is suspended. Membership is open to any registered medical man who, at the time of his election, is residing within a twenty-mile radius of Charing Cross. Relief is granted only to the widows or orphans of deceased members. Full particulars may be obtained from the secretary of the society at 11, Chandos Street, Cavendish Square, W.1.

The London Irish Medical Golf Society will hold its annual general meeting and dinner at the Charing Cross Hotel on Thursday, Nov. 23, at 7.30 p.m.

The opening of the Dublin office of Burroughs Wellcome and Co. at 18, Merrion Square was celebrated on Nov. 12 by a dinner attended by the Lord Mayor of Dublin and by leading members of the medical, dental, veterinary, and pharmaceutical professions. It was presided over by Mr. Leslie G. Matthews, who said that the office was intended to place the scientific and technical resources of the Wellcome Foundation, Ltd., more readily at the disposal of the company's customers in Ireland. Dr. H. J. Parish (clinical research director of the Wellcome Foundation) welcomed his medical colleagues, who included Prof. J. W. Bigger (Dean of the Faculty of Physic, Dublin University), Prof. J. M. O'Connor (Dean of the Faculty of Medicine, National University of Ireland), Dr. Bethel Solomons (President of the Royal College of Physicians of Ireland), Dr. Andrew Ryans (President of the Irish Medical Association), and Dr. J. Deeny (Chief Medical Adviser, Department of Local Government and Public Health of Eire).

The London Medical Exhibition, which has been resumed after a wartime break, attracted considerable interest this week at the Royal Horticultural Hall. There was a display of the products of over one hundred firms which was supplemented by the exhibition of medical films. Every variety of drug, appliance, and book was on view and reflected the current interests and recent advances in medicine. The film shows, illustrative of some of the best in this rapidly expanding field of educational aid, were well attended. The publications of the British Medical Association were well represented. At a time when degrees and diplomas are of such interest to medical graduate and undergraduate alike it is to be regretted that there should be such a shortage of paper for recent medical books whose variety, format, and contents continue to bring credit to British medicine throughout the English-speaking world.

Plans for a new cancer hospital in New York, to cost nearly £750,000, have been completed. It will be known as the James Ewing Hospital for Cancer. The hospital will be twelve stories high and will contain laboratories, offices, classrooms, and wards. It will be administered by the City of New York.

Dr. Otto May, F.R.C.P., who died on Aug. 15, 1946, left £38,117 gross, with net personalty £37,580

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* an increase was recorded in the notifications of measles 490, whooping-cough 50, and dysentery 10. A decrease was reported in the number of cases of diphtheria 40, paratyphoid fever 23, and scarlet fever 22.

Measles is prevalent in only a few counties, and almost one-third of the total notifications were reported from the counties of Lancashire and Durham. The largest rises during the week were Lancashire 175, Middlesex 101, Northumberland 100, and Kent 52; the largest fall was Sussex 40. The only appreciable variations in the incidence of scarlet fever were a fall in Yorkshire West Riding 37 and a rise in Lancashire 20. The rise in the incidence of whooping-cough was most marked in Lancashire 54 and Yorkshire West Riding 29; the only decreases of note were Devonshire 24 and Derbyshire 23. Although a relatively large decrease in cases of diphtheria was recorded for the whole country the notifications in London were more than doubled by an increase of 18, giving the highest total for the metropolis since the middle of April. The only large returns for dysentery were London 15 and Yorkshire West Riding 11. The decline in the notifications of paratyphoid was due to a decrease in the outbreak in Yorkshire West Riding, where 51 of the 66 cases were notified; 38 cases of paratyphoid were notified in Sheffield C.B., and the origin of this outbreak has still not been established.

In *Scotland* infectious diseases were more prevalent, and the rises included measles 60, scarlet fever 51, whooping-cough 45, and pneumonia 17. Dundee had 130 of the 222 notifications.

In *Eire* the only changes of note were increases in whooping-cough 19 and diphtheria 11 and a decrease in diarrhoea and enteritis 9. The incidence of diphtheria 47 was the highest since April.

In *Northern Ireland* there were a further 25 cases in the outbreak of measles in Belfast C.B.

Week Ending November 9

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 1,323, whooping-cough 1,590, diphtheria 314, measles 3,987, acute pneumonia 601, cerebrospinal fever 46, dysentery 65, acute poliomyelitis 21, paratyphoid 30, typhoid 5.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Nov. 2.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

It is still not possible to publish the return of births and deaths for Eire for the week ended Nov. 2.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. House, Tavistock Square, London, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aithology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulote, Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Buffalo's Milk and Tuberculosis

Q.—It is commonly believed that buffalo's milk is safer than cow's milk from the point of view of tuberculosis. Is this correct?

A.—Judged by experimental inoculation, there is no reason to believe that the Indian water-buffalo, which is found throughout India, Burma, and the East, and is used to some extent in the West Indies, is any less susceptible than the ordinary cow. On the other hand, in its native locality the buffalo does not seem to be exposed to any great extent to the risk of tuberculous infection, and what little information there is available suggests that in most parts of the world the incidence of tuberculosis in the buffalo is very low indeed. The chances, therefore, of finding tubercle bacilli in buffalo's milk must be small. There are some exceptions, however, since it is reported that in Egypt tuberculosis in buffaloes appears to be by no means infrequent; in fact, 60% of the buffaloes slaughtered in the Alexandria abattoir in 1937 showed macroscopic lesions of this disease.

Basal Anaesthesia

Q.—What exactly is a basal anaesthetic?

A.—A basal anaesthetic is a drug used to maintain a constant basal level of anaesthesia below which the depth is varied by the addition of another agent. The commoner term "basal narcotic" indicates the level usually considered desirable. This definition applies to nitrous oxide when used with, say, ether or intermittent injections of thiopentone, as well as to drugs having a prolonged action (bromethol, pentobarbital) which are given in a single dose. It is not applicable to the short-acting barbiturates when used for induction of anaesthesia—their action is more comparable to that of ethyl chloride before ether.

D.D.T. and Raw Vegetables

Q.—With the wider use of D.D.T. to prevent parasites attacking vegetables, and in view of the fact that it is not destroyed by ordinary washing, is it likely to cause toxic manifestations if large quantities of raw vegetables are eaten? Is it affected by boiling? Has D.D.T. any action on protozoa or on worms?

A.—D.D.T. is far less toxic to man than other insecticides (such as nicotine, lead arsenate, etc.) which have been in use for many years without danger to vegetarians. Because of its high toxicity to insects, only low concentrations are used in field applications. It is not affected by boiling water, but ordinary rinsing is likely to leach off a good proportion of the residue. Like any organic chemical, D.D.T. in excess is toxic to all forms of life; but it is specifically deadly to insects, crustacea, and certain other arachnids. Protozoa and worms are comparatively unaffected by it.

Penicillin and Normal Saprophytes

Q.—To what extent does penicillin affect the symbiotic bacteria? If it destroys them, is there any lowering of resistance to intestinal or, in the female, to genital infections?

A.—By symbiotic bacteria the questioner presumably means the normal saprophytic flora of the body. Most of these micro-organisms are entirely unaffected by penicillin administered

systemically in ordinary doses. The drug does not reach the skin or the intestine. In the latter situation most of the normal bacteria are in any case resistant to penicillin. In the mouth however, most of the species are penicillin-sensitive and may be affected by very large doses given systemically, or by sucking penicillin pastilles. It has been observed that after such treatment the suppression of normal types is followed by the appearance of penicillin-resistant organisms, such as coliform bacilli, which are not normally found. It is possible that such a transformation of the flora may occasion harm but there is no clear evidence of this. We know of no observations on similar effects resulting from local treatment in the female genital tract; systemic treatment would be unlikely to cause any such change.

Infestation of Stored Flour

Q.—I have been advised not to lay in a store of flour because it may become "mity" or "weevilly"? What are these "insects"?

A.—"Mity" flour is due to infestation with *Tyroglyphus farinae*. The larval nymph of this mite is common in dust especially in grain stores, and is spread from place to place on flour sacks. It may be carried about on flies and clothing and can survive for many months. "Weevily" flour is due to infestation with the larval stages of certain beetles, especially *Calandra granaria*, which feeds on, and lays its eggs in, grain.

Infectiousness of Infectious Diseases

Q.—When do the infectious fevers become infectious? For instance, is a child who is developing mumps liable to infect other children during the whole twenty-one days of the incubation period?

A.—This question cannot be answered dogmatically. The "infectiousness" of a fever is, in the first place, dependent upon the ability of the host to liberate organisms. In some diseases the organisms multiply superficially and, as it were, never leave the portal of entry. In such cases the host will be infectious from the time he receives the organism. Scarlet fever, tonsillitis, diphtheria, and meningococcal meningitis would fall into this category. In other diseases it is considered that the organisms multiply internally and are thus only able to be liberated when the infection is about to become manifest. Thus, measles, rubella, whooping-cough, and mumps become infectious towards the end of the incubation period as the virus begins to reappear in the oronasal secretions. Again, in chicken-pox and smallpox the primary infection is of the upper respiratory passages and the virus can be liberated towards the end of the incubation period. The evidence of the duration of the incubation period in smallpox contacts would suggest that smallpox is most infectious just before the rash makes its appearance.

In the second place, the "infectiousness" of a fever will depend on the amount and virulence of infecting agent that the host can liberate. Looked at in this way the case of mumps which developed after an incubation period of twenty-one days would show an absence of infectivity during the greater part of the early incubation period; during its last few days infectivity would gradually increase to become greatest during the onset of the disease, thereafter disappearing in a rapid diminuendo.

Exercise Tolerance

Q.—Is there any standard exercise tolerance test? If so, will you please give details?

A.—The standard test, which has been used widely since its introduction by Sir Thomas Lewis in relation to his work on "effort syndrome" during the 1914-18 war, is to make the patient step up on to a suitable stool or chair, 18 in. (45 cm.) high, twenty times during a period of about one minute, recording the heart-rate before, immediately afterwards, and subsequently at one-minute intervals, until the resting rate is resumed, or for five minutes. In normal healthy subjects, emotionally stable and at ease, the heart-rate returns to the resting level within one minute.

It should be clearly understood that this test is frequently abnormal in anxious, nervous subjects, and especially in those with an anxiety state, and it is often normal in patients with

established heart disease with good myocardial reserve. It is therefore of limited practical value in clinical medicine. On the other hand, it is very helpful where a combination of physical fitness and mental stability is required—e.g., in the selection of pilots, commando troops, and so on.

Use and Abuse of Pituitary Extract

Q.—(a) It is categorically stated in most textbooks that posterior pituitary extract ("pituitrin") should never be used in the first stage of labour, but its use is widely recommended in certain cases of accidental haemorrhage during the first stage. Can you explain this contradiction? (b) Can oxytocin ("pitocin") be given to induce labour in cases of rupture of the membranes prior to the onset of labour where there is no disproportion or malpresentation?

A.—Although the authors of some textbooks are not always consistent in their statements about the use of posterior pituitary extract before and during labour, the inconsistency is often more apparent than real. The dangers of giving such oxytocics are to both the mother and the child, and these should be borne in mind when considering this problem. Giving posterior pituitary extract may result not only in "contraction ring" formation, extensive cervical tears, and ruptured uterus, but also in death of the child from intrauterine asphyxia (when the placental circulation is impeded by violent and sustained contractions) and from intracranial injury. When the patient is not in labour and the uterus is relatively quiescent a violent response to pituitary extract is less likely than if labour has begun. Therefore those who advise against its use in the first stage of labour may still think it proper to give it to induce labour. Even for this purpose, however, it is falling into disfavour.

When the membranes have ruptured and a good deal of liquor has escaped the danger to the child is increased. This is true even when the membranes are ruptured artificially, and not many would regard it as safe to use oxytocin in such circumstances. Nevertheless the membranes are not as a rule ruptured artificially unless the foetal head is already low in the pelvis and the cervix is taken up and the prospects for easy delivery are good. When the membranes rupture prematurely of their own accord it often means that the presenting part is high and not fitting well—there may be a posterior position, etc. In general, therefore, the risks of giving oxytocin in such circumstances are greater than when the membranes have been ruptured artificially.

The case of accidental haemorrhage is a special one. Here it should be recognized that oxytocin is advised only if the uterus is quiet and not contracting. This often means that the power of the uterus to contract is impaired, so there is little chance of a violent response. Moreover, unlike delayed labour, the obstetrician is here faced with a complication which threatens the life of the patient—one where the risks are greater than the risks of giving oxytocin. Again, if the condition is so severe as to necessitate the use of posterior pituitary extract, the child is almost sure to be dead already, and the risk to the foetus from such treatment need no longer be considered.

Re-inoculation with T.A.B.

Q.—Three years ago a patient had the first T.A.B. and tetanus toxoid injections, but never the subsequent ones. What is the present state of his immunity?

A.—After a single injection of a foreign protein acting as an antigen, the cells concerned with the production of antibodies become sensitized so that a secondary injection, after an interval of months, or probably years, will evoke a good response in the way of antibody production. The important factor is that the first injection—the primary stimulus as it is called—should be adequate to prepare the tissues concerned to react to the secondary stimulus. In the case cited, this requirement will have been fulfilled if the first inoculations contained the recommended dosage of T.A.B. vaccine and of tetanus toxoid, and therefore similar injections should be sufficient to stimulate the necessary production of antibodies to give protection. The matter could, of course, be put to the test by withdrawing a sample of blood two to four weeks after injection to find if the serum contains a high titre of agglutinins to the typhoid

and paratyphoid bacilli. If the person is going abroad to an area where enteric is more prevalent than it is here, he should be advised to have a further injection within six months' time.

Inheritance of Hodgkin's Disease

Q.—A male patient, aged 30, has Hodgkin's disease. What is the likelihood of any future offspring being affected? He has had one healthy child conceived before the disease was apparent.

A.—There is no likelihood of Hodgkin's disease being transmitted from the father to his child. One case is on record, although it is not above criticism, of maternal transmission. The number of authenticated instances of two or more cases in the same family are very few. It is safe to say that the disorder is neither hereditary nor communicable. There is no reason to anticipate that the child would be affected in any other way.

INCOME TAX

Car Transactions

W. G. is employed by a local authority and receives a car allowance. He sold his car in September, 1946, and bought another for £346 (including tax). The car allowance does not cover the full costs of running the car, including periodical replacement.

* He is entitled to an initial allowance of 20% of the cost of the car excluding the tax (the tax ranks as an expense), and wear-and-tear allowance for 1946-7 at 25% per annum on the same figure. As against that he will have to bring in any income tax profit on the sale of the old car and, of course, any excess of the car allowance over the running costs. Some restriction may be due for private use of the car.

R. L. has been in general practice for some years. He bought car "A" in 1940 for £200 and car "B" in 1942 for £120. Car "A" was sold in October, 1946, for £475; car "B" will be sold shortly and replaced by car "C" to cost £x.

* The liability for the current financial year will not be affected, but in calculating R. L.'s liability for the year to April 5, 1948, he can claim in respect of car "C" the "initial allowance" of 20% of £x, and the wear-and-tear allowance of 25% of £x. He will, however, be liable to a "balancing charge" on car "A" (apparently £475-£200=£275), and similarly as regards car "B" if a profit should be realized on the sale of that car—vice versa if a loss should be incurred.

J. R. holds an appointment as a medical superintendent. He sold his car in 1944 when serving in the R.A.M.C. His duties now necessitate the use of a car and he has purchased one for £500—presumably after April 5, 1946. What can he claim?

* Nothing can be claimed in respect of the old car. Assuming that the necessity for using a car arises in the performance of the duties of the appointment, and not, for instance, in travelling from his residence to the hospital, he can claim in respect of the new car for 1946-7 (a) the initial allowance of 20% of £500=£100, and (b) depreciation at 25% per annum of £500 for the period from the date when the car was brought into use to April 5, 1947.

Private Use of Car

X. Y. Z. runs two cars for professional and private use; his coupons are partly "basic" and partly "E" coupons. How can he deal with a request to indicate the proportion of professional to private use?

* Assuming that both cars are used for both purposes and that records of the professional and private use are not kept, the only way of dealing with the request appears to be to estimate the respective mileages. Clearly no precise figures can be substantiated, but inspectors of taxes are aware of the difficulty and generally a reasonable figure is accepted without further evidence.

Cost of Locumtenent

R. W. employed a locumtenent during his summer holiday, providing "board and lodging for himself and his wife . . . equal to those of a first-class hotel." He asks what is the maximum amount that can be claimed as expenses.

* The admission of a claim to deduct the cost of a locumtenent's services is based on practice rather than on any specific rule of law. R. W. might claim to deduct the general expenses of the establishment less some allowance for the fact that his own personal effects, etc., remain on the premises, but it is possible that the Revenue may contend that the claim should be limited to the additional cost of the establishment incurred by reason of the employment of the locumtenent.

LETTERS, NOTES, ETC.

Ichthyol

Surg. Lieut. G. B. HOPKINS (Portsmouth) writes: I note a reference to ichthyol in the *Journal* of Oct. 12 (p. 562), in response to a question upon the action of ung. ichthyol upon inflammation. The answer appears to follow the lines of the standard pharmacological textbooks, even that excellent and critical tome by Goodman and Giltman, *The Pharmacological Basis of Therapeutics*. The unanimity of the subject matter relating to ichthyol may be construed in two ways: it may be largely correct, or it may represent an uncritical textbook survival. A chemist friend of mine several years ago queried a possible relationship between ichthyol and the sulphonamides; this suggestion merits consideration. Ichthyol is obtained by neutralizing with ammonia the sulphonated product of the destructive distillation of a bituminous schist, formerly obtained from Tuscany, and now from wider areas of southern Europe. The schist is regarded by geologists as having originated by fossilization of sea birds' excreta—an explanation which, though often presented dogmatically, is presumably open to controversy. From a perusal of chemical dictionaries such as Allen's and Thorpe's, and much delving into past numbers of the *Pharmaceutical Journal*, the *Journal of the Chemical Society*, and the *Journal and Proceedings of the Institute of Chemistry*, I came to the conclusion two or three years ago that ichthyol had never been subjected to close chemical analysis, and I was able to find an empirical formula only. Ichthyol contains carbon, hydrogen, oxygen, nitrogen, and sulphur; and these facts, in association with the sulphonating process, which was introduced to increase the sulphur content in the belief that the efficacy of the product lay therein, render it possible that a para-amino benzene sulphonamide derivative may be present. As a student I was dissuaded by one of my professors from swallowing ichthyol and testing for conjugated sulphonamide excretion products. The late Col. Marsh, senior E.N.T. consultant to the Birmingham United Hospital, told me that he was first introduced to the use of ichthyol when he went to Birmingham from Barts., and that he considered it sufficiently useful to prompt him to prescribe it for the rest of his life. The *Index Medicus* gives numerous references, few of which throw any light upon a possible chemotherapeutic action of ichthyol; but I found that Russian gynaecologists had used ichthyol by intramuscular injection for the treatment of pelvic infection. I was unable to follow up this reference. As a matter of historical interest, I should be happy if the above facts and conjectures prompted one of the manufacturing pharmaceutical firms to investigate the chemical composition of ichthyol and its biological action. The topic is one which would have appealed to Sir Walter Langdon-Brown were he still alive. I write entirely from memory and regret that I am unable to give any references.

A Lethal Plastic Bib

Dr. J. H. FODDEN, pathologist to the Royal Salop Infirmary, Shrewsbury, writes: I would like to place on medical record a most tragic and unfortunate happening which determined the death of a three-months-old baby boy. The child had been placed in his cot for sleep, with a clean plastic bib tied loosely around his neck. The bib was small, and was designed to fasten only around the neck with two pieces of tape. It was almost as thin as tissue paper, and just as transparent. When the child was next seen he had been dead some hours. The thin plastic membrane covered his face, almost as completely as his skin. It took up every contour of the eyes, the nose, and the lips. The post-mortem examination which I made showed that the child had been asphyxiated. The bib seemed to become very slightly "tacky" after it had been warmed in my hand for some time. Then when it was placed over the child's face it spread quickly into the position of a close-fitting mask. I am quite sure that myself and my witnesses hope never to see a repetition of such an experiment in similar circumstances. I have the permission and support of Dr. W. B. A. Lewis, H.M. Coroner, Oswestry and District, to make notice of this death through misadventure.

Urobilinogen Excretion in Infective Hepatitis

Dr. M. WINTERNITZ (Prague) writes: The question on urobilinogen excretion in infective hepatitis ("Any Questions," Aug. 10, p. 215) prompts me to a few further remarks and a slight correction of the answer given. The aldehyde test, as it is called for brevity (*recte* Ehrlich's *p*-dimethylaminobenzaldehyde reaction), is used on the Continent not only in infective hepatitis but as one of the routine tests in every urine examination. Its usefulness, however, can only be appreciated if the urobilin metabolism in the human body is well understood. Ubg. (urobilinogen) is formed from bilirubin through the reducing action of the upper intestinal flora. It is partly excreted in the faeces, partly reabsorbed into the portal blood stream. But it is not to any considerable extent excreted into the bile, as your answer maintains, but is reconverted into bilirubin in the liver cells. This can easily be shown by examination of the

duodenal bile, aspirated from a Ryle's tube. Normally the aldehyde reaction is negative, whereas the more sensitive urobilin reaction is weakly positive. Large amounts of Ubg. found in the duodenal contents or in bilious vomits occur with increased haemolysis, with infections of the bile passages by certain bacteria, and with diffuse liver damage, as in Laennec's cirrhosis. The normal urine contains only traces of Ubg.—slightly more after meals. Pathological Ubg.-uria, due to failure of the liver to reconvert Ubg., is found not only in diseases of the liver, such as infectious hepatitis, but in most infectious diseases, particularly lobar pneumonia, scarlet fever, rheumatic carditis. Its absence in certain diseases such as typhoid is of diagnostic importance. The aldehyde test is an important guide in congestive heart failure. In chronic nephritis and malignant hypertension Ubg. is poorly excreted by the kidneys and even normal traces are usually absent. Thus in hypertensive heart failure a strongly positive aldehyde reaction will at once exclude malignant hypertension—important information for contemplated mercurial treatment. The absence of more than traces of Ubg. from urine and faeces in the presence of frank jaundice points to the absence of bile from the duodenum; while its presence excludes complete obstruction of the bile passages. The reappearance of Ubg. in the urine in such cases is a welcome sign of recovery. Incidentally the positive aldehyde reaction must not be confused with the red or pink sediment produced by the reagent in the presence of sulphonamides.

Recent Advances in Anaesthesia

Dr. J. B. GURNEY SMITH (Dunfermline) writes: I have read the article on "Recent Advances in Anaesthesia" by my learned teacher, Dr. C. Langton Hewer (Oct. 12, p. 531), with considerable interest. I was, however, a little surprised to observe that no mention is made of the use of intravenous anaesthesia and the administration of pentothal. I have always imagined that the introduction of this drug into surgical work represented a major advance. I can speak from personal experience, having had it myself, and I recall that I slept for some four to five hours following the operation, and that there was none of the unpleasant post-operative anaesthetic sequelae usually associated with inhalation and spinal anaesthesia. Perhaps Dr. Langton Hewer would be good enough to enlighten me as to how "recent" is pentothal anaesthesia. It certainly seems to have established itself in the modern anaesthetist's armamentarium.

Rail Travel for the Sick

Major F. A. EVANS, R.A.M.C., writes: Recently I made use of a facility which is perhaps not as well known as it might be—namely, the moving of bed-ridden patients by rail. I accompanied an aged relative with complete hemiplegia from Euston to North Wales, using a special saloon with a very comfortable single bed. Settee and arm-chair for the use of the sister in charge, independent accommodation for relatives and luggage compartment, provision of electric kettle, bed-pans, etc., all gave an air of self-contained privacy. Meals, of course, could be obtained from the dining-car. The patient emphasized how perfectly comfortable and contented she had felt throughout the journey.

Disclaimer

Dr. A. KENNETH YOUNG writes from Tarbert, Argyll: I wish to disclaim responsibility for a paragraph on the back page of the *Scottish Sunday Express* of Nov. 10, in which I was quoted under the heading "Milk Revolt by Doctor." This paragraph was intended to represent an interview with me, when, in fact, it was a reconstruction of a letter of mine which appeared in the *Scotsman* a few days earlier and in the *British Medical Journal* later. Following the letter in the *Scotsman* an *Express* reporter telephoned me to ask how I intended to continue supplying priority milk certificates as before, and I explained to him that I should do so simply because I had always adhered rigidly to the requirements of the priority schedule and regulations. He then suggested that I might grant him an interview at a future date, but I told him plainly that such could only be the case if my name was withheld in accordance with professional etiquette. No further interview took place, and the next thing I knew was the somewhat sensational paragraph already referred to. I have already been in touch with the paper concerned and they are most apologetic.

An Error Corrected

Surg. Capt. H. PARRY-PRICE, R.N.V.R., writes: Dr. Langton Hewer has drawn my attention to an error appearing in my recently published book, *Practical Anaesthetics*. On page 69 it is stated, "Hewer says that the mortality in toxic goitre operated upon with auricular fibrillation is 30%." It is quite unnecessary for me to state that this should read 4.7%, and I apologize to Dr. Hewer for attributing such a statement to him.

Correction

In an annotation on "Insects, Mites, and Asthma" (Aug. 31, p. 304) mention was made of a report by "Ordman." This should have been "Ordman," and refers to Dr. David Ordman of the South African Institute for Medical Research.
